UNDER this heading various writers in the lay press have been discussing what they are pleased to describe as the "irresponsible and autocratic behaviour" of the General Medical Council in regarding canvassing as "infamous conduct," and punishing the offender according. The surprise is all on our side since these self-same critics have not a word to say regarding the vastly more stringent disciplinary rules enforced by the Incorporated Law Society. For a man to describe himself as a solicitor is an offence automatically and swiftly followed by punishment, whereas the punishment of a similar delinquency on the part of an unqualified person in respect of a medical title often presents great difficulty. If a solicitor touted for clients the Society would not fail to bring home to him a sense of his responsibility, and rightly so,

yet the legal and judicial officials affect astonishment and even dismay at the idea of similar powers being vested in, and exercised by, the General Medical Council. The fact is that these arguments and attitudes are merely party tactics intended to offer a loophole of escape to those members of the medical profession who are willing to ignore the higher interests of their profession in deference to sordid motives. Fortunately the movement is one which must of necessity end in smoke, but it would be more satisfactory if the public could be brought to see that in this instance, at any rate, the interests of the medical profession are identical with their own. The mere idea of an advertising medical profession ought surely to carry conviction though perhaps not to the lay press which of course would stand to win untold profits thereby.

Foot-Gear.

LOOKED at from an anatomical standpoint, it is as unreasonable to expect to get a well-fitting and suitable pair of ready-made boots as it would be to suppose that one could get a comfortable set of ready-made false teeth. This may appear a somewhat startling theory, yet its general acceptance, while certainly doing the trade of bootmakers no harm, would prove very beneficial to the rising generation, if not to the present. Although there are broad general lines, now fairly well understood on which boot construction should be conducted, the difficulties in deciding what is best in individual cases are exceedingly great. How to encase the movable foot—the best use of which depends on the ease with which its highly complicated articulations are allowed their proper range of movement under varying conditions of weight and position—a boot which will not interfere with these movements, is a difficult problem Dr. J. A. Sampson, in an exhaustive paper on the subject of "Proper Footwear," (a) has recently indicated many practical points, attention to which will prove most valuable to those who may be consulted on the choice of boots and the correction of deformity; in concluding his paper Dr. Sampson returns special thanks to his own feet, which have for three years stood all kinds of experiments without grumbling. It may be remembered, that it was due to Stromeier's success in operating on Little, that the latter returned to England prepared to extend the benefits of subcutaneous tenotomy to others.

Infectious Kisses.

It is almost incredible, in view of the extremely infectious nature of diphtheria, that intelligent people should allow children to run a serious risk of contracting this deadly disease by kissing the body of a schoolfellow who had succumbed thereto. An outbreak due to that cause is reported from Little Clacton, and several deaths have occurred. Even among apparently healthy children the practice of mouth-kissing should be sternly discountenanced, since, as is well known, the habit is fertile in mischief.

(a) *Johns Hopkins Hospital Bulletin*, January.

The Fate of a Medical Anti-Vaccinator.

A RECENT incident in the career of Emmanuel Pfeiffer, M.D., of Boston and Bedford, Massachusetts, comes very opportunely to illustrate the fallacy of the anti-vaccinationist propaganda. This gentleman, according to the *New York Medical News*, was one of the most vigorous and intelligent anti-vaccinationists of his neighbourhood, and his thesis was that small-pox is not a contagious disease for healthy persons, but is the product of bad hygiene and an evil diathesis. So convinced was he of the truth of this view that, bolder than many anti-vaccinationists of whom we have heard, he solicited permission to visit the Boston Isolation Hospital without being vaccinated. His formal request was acceded to, after mature consideration, and on January 23rd he went through the wards, taking all the precautions which other visitors take under similar circumstances, such as the wearing of a close bound gown and cap, washing the hands, beard, hair, &c., on leaving, and so on. For the next ten days, more or less unknown to himself, he was kept under observation by physicians from the Board of Health, but on the eleventh day he suddenly became conspicuous by his absence at his "office," and his secretary stated that he was travelling. No news could be obtained of his whereabouts until on the fifteenth day after his visit to the small-pox hospital, a notice was received that he was ill at his home in Bedford of a disease which experts pronounced to be a bad attack of the disease in the confluent form. Hopes are entertained that he may recover, and we do not grudge him this victory because he has involuntarily done great service to the cause of small-pox prevention by means of vaccination. Whether this drastic experience will convince Dr. Pfeiffer of the error of his ways is another matter, for the human mind is curiously constituted in regard to such matters. The incident is a pendant to that of the unvaccinated nurses at the Mile End Infirmary, who one and all contracted the disease, while their revaccinated sisters all escaped.

"Ladies' Bars."

Is it a sign of the times that we see springing up in various parts of the metropolis departments in public-houses specifically allocated to lady customers? Can it be that the enfranchisement of women is developing in the direction of imitating certain masculine habits, not in themselves worthy of commendation? It may be, of course, that the "Ladies' Bars" merely indicate that jealous man resents the intrusion of the fair sex into the secluded haunts where it is his wont to talk loudly and freely of his private affairs, a habit which obviously paves the way to subsequent trouble if indulged in promiscuously. We hesitate to believe that these signs are conspicuous evidence of the law of supply and demand in respect of the bibulous propensities of the "ladies" of this country. The ravages which alcohol makes among women are, in all probability, not fostered by the facilities offered for drinking in

public places, but rather by the ease with which flagons of strong drink can be smuggled into the house among the groceries, the effect being usually more in evidence than the cause, which, on diligent search, begotten of an uneasy suspicion, may be revealed only by an unaccountable abundance of empty bottles. The problem is one which bristles with difficulties, but we question whether the advantage of keeping "ladies" out of the public-houses is not more than compensated by the ease which grocers' licences offer for procuring secret supplies of spirits and brandied wines. By enabling the average housewife to indulge her morbid proclivity at home, the wholesome and deterrent influence of public opinion is withdrawn, to say nothing of the friendly, if somewhat gruff surveillance of the publican, who is not backward in conveying his impression that a particular customer has "had enough." No such moralist is at hand to check the thoroughly domesticated woman on her downward career—the more's the pity!

The Sex Mortality of Women.

THE question of the relative mortality of males and of females at various ages presents many interesting, and in some cases, hitherto unsolved problems. The women have the advantage in the first years of life to the extent of thirteen male to ten female deaths. That fact has not yet been satisfactorily explained, as the larger size of the head of the male at birth fails to account for the bulk of the mortality which falls upon the period of infancy and childhood rather than that of parturition. Between the ages of ten and twenty the women show a slight excess of deaths, due, to a great extent, to the earlier incidence of phthisis upon their sex. Formerly they showed an excess also during the child-bearing period, but of late years the introduction of aseptic methods has enormously lessened the risks incident to maternity, so that nowadays, speaking broadly, the mortality of men and women is about the same between the ages of five and thirty-five. From the last-mentioned point onwards the women hold the advantage until the end of life. Men have to encounter the stresses of hard work, exposure, and anxiety, all of which are apt to lay the foundation of degenerative changes in later life, and so lead to premature old age and death. The result is a considerable excess in the female over the male population, and many social readjustments due to the pressure of the struggle for existence. The question of sex and mortality is clearly of great importance in life insurance, the conditions of which have been simply revolutionised of late years as regards the lives of married women in the child-bearing period.

At the recent visit of the King and Queen to Portsmouth, her Majesty presented nine nursing sisters with their certificates. The nurses were introduced by Inspector-General Bolster, M.D., of the Royal Naval Hospital, Stonehouse.

The Physiology and Pathology of Kissing.

THE origin of many customs is veiled in prehistoric gloom, and many a time-honoured procedure still remains wrapped in unscientific uncertainties. The advantages of kissing have long been recognised and the practice is undoubtedly ancient. It has, however, become the fashion of recent days to seek out hidden dangers lurking in apparently innocent quarters, and it must be admitted that the act of kissing is not without its dangers, that is to say bacteriologically speaking. The whole subject is one which may well repay careful study. Kissing is defined by Dr. Christopher, the Professor of Romance and Philology at the University of Copenhagen, in his work on "The Kiss and its History" which has recently appeared in English dress, as, "An inspiratory bilabial sound which English phoneticians call the lip click, *i.e.*, the sound made by smacking the lip." Generally speaking, it takes two to produce an effectual physiological kiss. Not infrequently there is difficulty in selecting a suitable subject for a graduation dissertation or scientific thesis. We venture to suggest that the above-mentioned subject would afford ample opportunities for original investigation. Certainly the science and art of kissing, or the theory and practice of the same, would afford suitable titles on which to hang much useful and perhaps some useless information regarding the physiology and pathology of kissing. Perhaps, however, the candidate should first seek the approval of the powers that be.

The Health of the Naval Cadet.

It has long been recognised that the old training-ships, often constructed of wood, with limited air space and rich in sanitary defects of almost all kinds, were anything but ideal nurseries for the Navy. Indeed, it has been clearly shown that morbid conditions might be engendered by such non-hygienic surroundings. Phthisis, for example, has been conclusively proved to be more frequent in the wooden ships than in ironclads or healthy institutions on land. It is, therefore, with particular pleasure that we anticipate the good results which must accrue from the establishment of the new Naval College, at Dartmouth, the foundation-stone of which has just been laid by the King. At least a quarter of a million is to be expended on the new building which has been designed by Mr. Ashton Webb, A.R.A. Three hundred and sixty-four cadets and the officers, and at least a portion of the staff, will reside in the College. Separate sick quarters are to be provided with accommodation for sixty.

Death of Professor Kaposi.

WE regret to say that the great dermatologist, Kaposi, is no more. A telegram from Vienna states that he died from apoplexy on Thursday last, at the age of sixty-five. Dermatological science owes much to the research and painstaking investigation of a lifetime, which he had devoted to diseases of the skin. Kaposi and his father-in-law, the great Hebra, accomplished much in making sure founda-

tions for this branch of medical science. Kaposi was not only a great student but a famous teacher, and as a physician his reputation was world-wide. His publications are said to exceed 150 in number. With the death of Professor Moriz Kaposi, Vienna University loses one of its most distinguished men.

The Epidiascope.

THIS apparatus is designed for the projection of objects lying in a horizontal position. It allows of the projection of both opaque and transparent objects. Pickle specimens, illustrations from books, instruments and the like can readily be portrayed on the screen. It will be invaluable for lecture purposes. Although somewhat expensive, it will prove a great saving in the long run in replacing the necessity for expensive drawings and elaborate diagrams, and as regards convenience it leaves little to be desired. Every medical school should be equipped with one of these ingenious appliances. Full particulars can be obtained from Carl Zeiss, of Jena, the manufacturer.

The Binoxide of Sodium.

PROFESSOR DESGREZ and Dr. Balthazard, of Paris, have just made public some interesting results obtained by them with the binoxide of sodium. This salt has the property of liberating oxygen which, in its nascent state, promptly destroys the poisonous substances of respired air, choke-damp, &c. It thus purifies contaminated air and restores the proportion of oxygen. It is hoped that, with a supply of the salt in a headpiece it may be possible to carry on explorations under water, in mines, &c., without the cumbersome and often dangerously complicated apparatus at present in use.

Accidental Electrocution.

THE force of electricity is an all-pervading influence, beneficent when safeguarded aright, but deadly when left unfettered. The sad case of electrocution at a Sheffield theatre recently indicates the need for care and caution. The victim was a workman at an electrical works and received a charge, which proved fatal within ten minutes, from a brass bracket used for lighting the Theatre of Varieties at Sheffield. The current, it is said, did not exceed 200 volts. It is to be hoped that those responsible for the safety of the public will see that every precaution is taken to ensure due protection.

Suture of the Heart.

ANOTHER case of wound of the heart in which recovery followed suture has been reported by Watten. In this instance a thoraco-plastic operation was done, and a wound in the right heart closed with two sutures after some difficulty. One point of considerable interest in the case is that the surgeon was obliged to introduce his hand into the pericardial sac behind the heart in order to steady it sufficiently to allow of the introduction of the sutures. The closing of the wound is said to have resulted immediately in a less tumultuous heart's action, and the

patient made a complete recovery, the pneumothorax caused by the operation soon disappearing. Such a case as this evidences how much handling the heart will bear without ceasing its work.

King Edward's Hospital Fund for London.

THE annual meeting of the General Council of this fund was held on the 7th inst. at York House, H.R.H. the Prince of Wales occupying the chair. The report shows steady progress in spite of the drain caused by the war, last year's receipts being in excess of those of the preceding year. It was stated that the grants had for the most part been limited to hospitals and it had been deemed necessary to restrict the operations of the fund to institutions situated within the seven mile radius of Charing Cross. The expenses had been less than 3½ per cent. on the amount collected, which affords sufficient evidence of economical management. The Prince of Wales was enabled to state that £20,000 out of the desired £50,000 a year had already been promised, and he expressed the hope that the necessary capital of a million sterling would be obtained during the Coronation year, in order to free the London hospitals for ever.

Arsenic as a Cause of Beri-beri.

It will be remembered that when cases of arsenical poisoning from beer-drinking were first observed at Chester during the great "epidemic" of arsenical poisoning in the North of England, Drs. Newall and Prytherc, fortified by the opinion of Professor Ronald Ross, considered that the peripheral neuritis occurring in their patients was but a manifestation of the obscure tropical disease known as beri-beri. Dr. Ross has continued his researches as to the possibility of beri-beri being really a form of chronic arsenical poisoning. Dr. Dixon Mann has examined the hair of some twenty cases, and in six he finds arsenic. From this Dr. Ross contends that "the probability is very strong that the Penang beri-beri is arsenical, especially when we know that the people there largely work in tin manufactories and are brought closely into contact with arsenic." All this is very interesting, but by no means convincing. If the cases are "brought closely into contact with arsenic," it seems likely that external contamination of the hair might readily arise; and even should a certain amount of arsenic be absorbed into the system in sufficient amount to be detected on chemical analysis, this surely does not prove beri-beri to be due to this toxic agent.

We sincerely regret to have to announce that Mr. John Lumsden Probert, M.B., Lond., M.R.C.S., and Chief Medical Officer of the Metropolitan Fire Brigade, a son of the Founder of the Royal Medical Benevolent College, died at his residence in Gloucester Place on the 7th inst.

On March 8th Major-General Sir Henry Trotter presented the distinguished conduct medal, together with the South Africa medal and clasp, to Private S. Nathan, of the Medical Staff Corps.

PERSONAL.

MISS LAMPORT has the honour of being the first woman doctor to be appointed to the post of public vaccinator, the guardians of Poplar having set the example.

DR. CABLE, of Greenwich, was thrown from his trap last week, the horse having slipped on the tram lines. Fortunately he escaped with a severe shaking, but his coachman sustained more serious injuries.

MISS KAPADIA, the lady doctor in charge of the Ranchodlal Zenana Hospital, has just passed the F.R.C.S. Ireland examination, being the first Parsee lady to take the diploma.

DR. W. B. MACDONALD met with a serious accident last week when cycling from Haddington to Dunbar, and he was found lying unconscious at the foot of Penoraik Hill, having sustained a fracture of the skull in addition to other severe injuries.

THE reports from South Africa regarding the health of Mr. Cecil Rhodes are of an alarming nature. He is said to be suffering from attacks of angina pectoris and dyspnoea, for the relief of which inhalations of oxygen are being administered. The medical man in attendance is Dr. Jameson.

Special Article.

THE MIDWIVES' BILL FROM AN IRISH STAND-POINT.

SEPARATE legislation for Ireland and England in such matters as the control of midwives cannot commend itself to any person who considers the points at issue. The poor in Ireland are as largely attended by midwives in proportion to their numbers as is the case in England, and the number of untrained women who pose as midwives is relatively as great. Consequently, if a Bill can be carried through Parliament by which the efficient control of midwives is guaranteed, such a Bill should include Ireland, and we believe would receive the approval of the medical profession in Ireland as a whole. Is the present Bill likely to ensure the efficient control of midwives and to check the practice of untrained women? We fear that the answer must be in the negative. It is notoriously the worst of its kind which has as yet been laid before Parliament. It is unnecessary to dwell at length on its faults, as these have been already pointed out with singular unanimity by the important medical bodies and journals throughout the country. It may be said to have awakened a universal chorus of disapproval, so far as the medical profession is concerned, starting from the time that Sir John Take declined to place his name upon its back, as he had done in the case of its predecessor. By all omission of a penal clause, the Bill fails to protect the midwives whom it certifies, and in that respect emulates the worst features of the Medical Acts. It ousts the General Medical Council from its necessary position of regulating and supervising authority of registered midwives, and substitutes lay authority in the form of the Privy Council. It constitutes a Central Midwives Board on which the bare majority of medical practitioners is so appointed that a majority opposed to medical control could readily be brought into existence. Lastly, the power which the Bill gives to County Councils to delegate their authority to District Councils will seem to anyone familiar with the present working of the Irish Poor-law Medical Service to be a most undesirable clause to appear in an Irish Act. We, therefore, have no hesitation in saying that the application of the present Bill to Ireland would not in

our opinion be of advantage to the country. A further question remains. If the present Bill, or even a modified form of it applying to England alone, is passed, how will it affect the position of midwives who have been trained in the great Irish midwifery schools? This is we know a matter which causes the keenest anxiety to all those familiar with the prestige and excellence of these schools. What they ask will be the position of midwives who have received the diploma of the Rotunda or Coombe Hospitals, a diploma which is already recognised by Act of Parliament? Is the Midwives' Bill to sweep away the powers conveyed by these charters? At present, the Bill recognises the certificate in midwifery of the Royal College of Physicians of Ireland as entitling holders to admission to the midwives' roll. This, in itself, is sufficient to show that the framers of the Bill are not acquainted with facts. The Irish College has ceased to issue certificates to midwives, and it is doubtful whether there are a dozen women practising as midwives who hold the College's certificate. Whereas the Rotunda and Coombe Hospitals have, we may say, hundreds of certified diplomates practising in England, all of whom have received a careful training, and have passed a searching examination. Surely the Bill requires a modification which will ensure that these women are placed on the midwives' roll, not as a favour, but as a statutory right, by virtue of the fact that they hold the certificate of an Institution appointed by charter to issue such certificates. Similarly, the possession of such a certificate should entitle the holder to obtain admission to the midwives' roll not merely at the inception of the Act, but subsequently. In other words, the Bill should include a clause to the effect that diplomates of existing chartered midwifery hospitals should not be obliged to pass the examination of the Central Midwives' Board. We may then sum up our views of the relations of Ireland to the present Midwives' Bill as follows:—A good midwives' Bill applying to Ireland is to be desired, but the existing Bill does not come under this heading. It is essential that in the case of any Bill the interests of the Rotunda and Coombe Hospitals and of their diplomates, should be rigidly guarded, inasmuch as these hospitals were incorporated by Royal Charter, the one in 1766 and the other in 1867, for the express purpose of training, examining, and certifying midwives. Mr. H. Heywood Johnstone, M.P., when the Bill of 1900 was before the Grand Committee on Law, stated that he would accept an amendment to the effect that the examinations of the Rotunda and Coombe Hospitals should be regarded as equivalent to that of the Central Midwives' Board. Surely, there will be no difficulty in securing the addition of such a clause to the present Bill.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

THE FORTHCOMING ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

CONSIDERABLE activity is now being shown in connection with the forthcoming visit of the British Medical Association. The committees which have been entrusted with the various necessary arrangements are meeting constantly, and have their work so well in hand that there is sure to be a good "picnic." The officials of the "sections" are also at work, and if all their invitations to discuss subjects and read papers are accepted there will be enough intellectual pabulum to fill the *Journal* for months. It would be a good plan, surely, to publish a thick special number of the *British Medical Journal* containing the whole of the literature relating to the meeting. These papers and discussions undoubtedly spoil the *Journal* for many weeks after the meeting every year, and they ought to be dealt with separately.

Judging from your own columns and from those of contemporaries, considerable interest has been displayed in the so-called "Manchester Brass Band." This has surprised the natives, for no one here ever supposed that the dulcet tones of the fraternity referred to would find listeners afar off. However, it is

proverbial, or rather Biblical, that prophets have no honour in their own country.

THE MIDWIVES' BILL

This must not be taken to mean that the bulk of the profession in Manchester is in favour of the present Midwives' Bill. On the contrary, there is probably not one among us who considers the Bill now before Parliament to be anything but a useless, if not a dangerous, attempt at legislation on a matter which would be much better let alone until the working-class public can be educated in cleanliness and other matters. If the present Bill becomes law there will be a rise in the mortality from puerperal fever. A local proverb, however, states that "Them as knows nowt fears nowt," and of such without doubt are the promoters of the Bill.

THE ROYAL VISIT.

The public interest is at present centred in the Royal visit, which is fixed for March 12th. There will be the opening of the Whitworth Hall at the Owens College in the morning, a lunch at the Town Hall, and a huge social function in the College in the evening. The next day there will be a Degree Ceremony and presentation of addresses in the Owens College. A large number of honorary degrees will be conferred, and the delegates and honorary graduates will dine with the College and staff in the evening. Preparations for the decoration of the streets have begun. The hoardings, which have for months obscured one corner of the College buildings, are down, and the pavement gives great promise of being complete once more.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

QUACK AND CRIMINAL ADVERTISEMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Whilst there can be no hesitation in condemning, as you do, many newspaper proprietors for their almost criminal neglect of the public welfare in knowingly opening their columns to the advertisements of cruel and fraudulent medical pretenders, it must be borne in mind that many editors and journalists have practically no belief in medical science, and rather pin their faith to those who base their opinions upon an anti-scientific foundation, or who pursue methods which to the professional eye are those of gross and palpable quackery. To this class mostly belong the party of anti-vivisectionists. Their attitude towards medicine was well exemplified in the letter on cancer addressed by that representative lady, Miss Frances Power Cobbe, to the *Daily News* a few weeks ago—a letter which was discussed in a leader in THE MEDICAL PRESS AND CIRCULAR. Other equally typical, prominent and influential members of Miss Cobbe's party are the Hon. Stephen Coleridge and the Rev. Canon Wilberforce.

The writings and speeches of Mr. Coleridge, the hon. sec. to the Anti-Vivisection Society, are familiar to many of us, and those who read the sermon preached by Canon Wilberforce on last Hospital Sunday are never likely to forget it. This sermon was commented upon editorially at the time by you and by most of the leading professional journals. The teachings and the preachings of leading anti-vivisectionists, whatever their intention, have had the effect of exciting widespread disbelief in medical science, and distrust and even hatred of its practitioners. The influence of a single dignitary of the Church of England like Canon Wilberforce is of incalculable weight. When a prelate holding the position of Canon of Westminster and Chaplain to the Speaker, delivers himself solemnly from the pulpit, his utterances have, with a large section of the British public, a weight almost equal to those of the Pope when speaking *ex cathedra* to the Catholic world. And it must be remembered that these teachings from pulpit, platform and press have been unremittently carried on during the past twenty years, not only by Canon Wilberforce, but by equally eminent divines, such as Bishop Barry.

A precisely similar effect in producing disbelief in medical science and distrust and suspicion of medical men has been brought about by the anti-vaccinators. These number in their ranks many prominent men, such as Mr. Hopwood, the Recorder of Liverpool, Mr. Corrie Grant, M.P., and Mr. Bernard Shaw. The last-named gentleman, well known as a writer, is said to be also a leading journalist. His writings have had throughout the tendency I describe. His very latest utterance is in the form of a letter to *The Times* of this morning (March 1st). He therein expresses a doubt whether the outbreak of small-pox at the Mile-end Infirmary was due to importation of a case of small-pox into the wards, and thinks it possible or probable "that the presence in the infirmary of a number of nurses suffering from various eruptions on the arm (that is to say, the re-vaccinated nurses) produced not only the outbreak among the un-revaccinated nurses, but also among the patients."! He distrusts the professional opinion that vaccine variola is not infectious, and suggests that it may be in fact more infectious than small-pox itself.

The effect of all such teachings on the so-called "educated" but really uncultivated and stupid classes has been illustrated in the position taken up by Col. Le Poer Trench in his championship of the "lachnanthes" cure for consumption—a subject in the discussion of which in your columns I, some little time back, took part. If the frame of mind there disclosed can be induced in "educated" men, there need be no wonder at the credulity and gullibility of the untutored multitude. They demand and will have quackery; and, as many of their pastors and masters believe quackery to be better than science, it may not always be just to blame newspapers which, holding similar opinions, lend the aid of their columns for reasonable payment towards promotion of what they consider a legitimate and, perhaps even as well, a beneficent industry.

I am, Sir, yours truly,

March 1st, 1902.

UBIQUE.

THE MANUAL INDUCTION OF ANÆSTHESIA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to the article with this title in your issue of Feb. 26th, I take the liberty of pointing out that Dr. Steiner displays an edifying degree of infantile innocence regarding the history of anæsthetic practice. If he, or any of your readers, will refer to an article on "Capital Punishment" which appeared in the pages of THE MEDICAL PRESS AND CIRCULAR of Nov. 13th, 1901, he will find the following item:—"It is not, we believe, very generally known that in the good old days of unlimited monarchical power, when executions, especially political ones, were carried out on so large a scale, when a rebel was drawn on a hurdle, hanged, disembowelled, beheaded, and quartered—hanging was used as an *anæsthetic*. From time immemorial in some of the Eastern nations partial strangulation was so employed before important surgical operations. And in the execution of an English rebel the hanging was by 'short drop,' and the culprit was cut down while still alive. He was then ripped open, and the heart and bowels were torn out and burned 'before his face' in a fire made ready for the purpose."

For tens of centuries before the introduction of what I may venture to call *chemical anæsthesia* this process of jugular production of unconsciousness before cutting operations was practised in many Oriental countries.

It was carried out either by manual pressure, as in the practice of the modern medicine-man of Java, or by pressure of a bandage, or rope, or some such utensil—sometimes utilised by the process of suspension.

It would be interesting to ascertain how Dr. Steiner came to know that the *internal carotid* artery is the vessel aimed at. Has the medicine-man of Java made a successful study of the anatomy of the vascular system of his fellow-man? Dr. Steiner's critic is surely right in saying that the *internal carotid* artery cannot be compressed "without at the same time obstructing the jugular vein." But he has not noticed the fact that the *external carotid* artery must also be involved in pressure applied at that

level—which is immediately above the situation of the bifurcation of the common carotid trunk into its internal and external branches—one of the most "constant" points, we may observe in passing, in the whole range of arterial anatomy. Now every surgeon who is intimately acquainted with the anatomy of this most important region, as every surgeon should be, must be conscious that pressure applied in the way described by Dr. Steiner, "below the angle of the lower jaw," is brought to bear exactly upon the line of division of the common carotid artery and both its divisions, and obstructs the arterial circulation in all three, as well as—necessarily—in the internal jugular vein. It is the proper position to select for the complete arrest of both arterial and venous currents.

Accordingly the resulting unconsciousness is very easily comprehended. Dr. Steiner's commentator tells his readers that "there is reason to suspect that the compression of the pneumogastric nerve and certain sympathetic filaments may also play a part in the production of unconsciousness. Well, there is at least one reader of THE MEDICAL PRESS AND CIRCULAR who would like very much to hear what the "reason" is!

Before concluding I will just relate an item of personal experience on this subject. Some years ago I was one day holding on my knee a bright and precocious girl of six to whom I was intensely attached. In the intervals of more serious conversation there had been a good deal of caressing and tickling going on.

It so happened that I had been reading but a day or two before something on this same subject of jugular anæsthesia; and a busybody spirit moved me to try whether my little playfellow would bear much pressure on the vessels of the neck without noticeable result. So I began to vary the tickling processes by making pressure along the course of the vessels of the neck—in long drawn strokes at intervals with the thumb on one side and the four finger-tips on the other. Each application began at the level of the angle of the jaw, and was prolonged to near that of the clavicle. As the individual strokes were made with studious gentleness, the little one enjoyed the play as fully as possible. As the experiment proceeded the pressure-strokes were deeper and more prolonged; when, on keeping up the obstruction a little longer than in any of the preceding contacts, to my unspeakable horror the little one's eyes became glazed, her neck and back (slightly) arched backwards, and her thumbs turned in in the usual eclampsia fashion. The insensibility lasted, I should say, about twenty seconds, when, with a sudden shuddering movement, both spasm and unconsciousness disappeared. Of course, I questioned her as to whether she had felt any pain or sensation of want of air before I took my fingers from her neck. She assured me that she had felt nothing of the kind. She had no knowledge whatever of what had occurred. There was absolutely no warning of the spasm or unconsciousness; both her hands had been free during the whole time and she had made no attempt to remove mine.

Needless to say, I did not repeat the experiment, nor do I intend to. But I am glad of the experience, as it gave me an object lesson of the possibilities of physiological anæsthesia which I am not likely to forget.

I am, Sir, yours truly,

JOHN KNOTT, M.D.

34, York Street, Dublin, March 1st, 1902.

A SENTENCE FOR REVISION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to the few lines you kindly published in your last issue, I may be allowed to state that the Home Office has been approached regarding this lamentable accident, and for some extraordinary reason appears to regard the sentence as one of no undue severity. It is evident from the accounts that a common assault was committed, but no direct violence took place, otherwise the post-mortem examination must have revealed it, and for this offence the prisoner might have been heavily fined, and although I have no desire to reflect on the deceased "De mortuis nil nisi bonum," the assumption is that there was extreme provocation

for the accident. Under all these circumstances, seeing that the medical profession has done more for humanity and the law than the law has done for us, I submit that a more charitable view of the case might have been taken.

I am, Sir, yours truly,

CLEMENT H. SERS.

Queen's Road, Peckham, S.E.,
March 7th, 1902.

Literary Notes and Gossip.

WE understand that the popular "Manual of Surgery," by Messrs. Rose and Carless, is now being translated into the Czech language, and that an edition will be published in Budapest in the spring.

DR. LUCOMME, of Lyons, is engaged in translating that scholarly work of Prof. Mayo Robson and Mr. Moynihan, on "Diseases of the Stomach and their Surgical Treatment." It affords us pleasure to congratulate the authors on the success of so sterling a work.

"WOMAN'S Best Work and Latest Capabilities," by Mr. F. J. Gant, F.R.C.S., has been honoured by acceptance of copies by H.M. the Queen and by H.R.H. the Princess Christian, who have graciously sent letters of acknowledgment to our *confère*.

A THIRD edition of Dr. J. Dixon Mann's well known work on "Forensic Medicine and Toxicology" has just been issued by Messrs. Griffin and Co. Arsenical neuritis having come very much to the fore since the previous edition was printed, this section has been rewritten in accordance with recent knowledge. We hope to review the book shortly.

WE are pleased to note that a memorial has been set on foot by the President and Council of the Pharmaceutical Society to perpetuate the name and the distinguished attainments of the late Mr. William Martindale, author of "The Extra Pharmacopœia." It is proposed that the memorial take the form of a marble bust and a medal or other prize in pharmacy.

THE new volume of the "Edinburgh Medical Journal" is, if anything, more interesting than any preceding issue. The original articles are numerous, pithy and suggestive; the selections, analytical reports and sectional reviews of the different provinces of medicine are such as the busy practitioner wants—brief, clear, practical, and dealing with the difficulties that occur in everyday practice. The illustrations are numerous and beautifully executed; and what is better, are well chosen and very helpful.

IN the third and cheaper edition of Quain's "Dictionary of Medicine," recently published, Messrs. Longmans explain that although the general scheme of the book as planned by the late Sir Richard Quain has been preserved, some departure has been deemed necessary by the editor, Dr. Montague Murray and his assistants. New articles have been introduced, others re-written, and the increasing incursions of Surgery into the realm of Medicine have received adequate recognition.

"ELEMENTARY Ophthalmic Optics," by J. H. Parsons, F.R.C.S. (recently published by J. and A. Churchill), is elementary in name only, as we venture to think that most practitioners and many specialists in ophthalmology would find the matter of this book the reverse of its title. It requires a distinctly mathematical brain to grasp it, and this the average student is scarcely expected to possess. As a book of reference, and in the solution of many optical problems it will be found excellent, evincing as it undoubtedly does much knowledge and scientific acumen on the part of the author.

ANY book that advocates a simple mode of living and diet is always to be welcomed. The older methods of attacking disorder and disease almost exclusively by medicine are now being replaced by the more rational methods of treatment by diet and healthy surroundings. It is, however, advisable to consider and prescribe for each person, according to his particular necessities, and the diets advocated in this little book, so exclusive of meat, would neither be tolerated nor necessary in even the uric acid diathesis. "Science in the Daily Meal," by Albert Broadbent, F.R.H.S., may be useful if only for its excellent culinary recipes.

THE same author has issued a companion pocket-book, entitled "Fruits, Nuts and Vegetables," in which he insists very briefly and conclusively on the nutritional and medicinal value of fruits, nuts and vegetables. Undoubtedly the abuse of a nitrogenous diet is productive of much metabolic disorder, and many persons would doubtless enjoy better health if their over-abundant nitrogenous diet were varied with fruits and vegetables. Simplicity in medicine is an excellent quality, but one hesitates to endorse the manifold and extraordinary cures which are stated in this book to result from the use of the various members of the vegetable kingdom.

UNDER the will of the late Dr. Nathaniel Rogers the Senate of the University of London offer a prize of £100, to be awarded next year, for an essay on "The Production of Immunity in Specific Infective Diseases Generally, and with particular reference to any one disease on which the writer of the essay may have made original investigations." The prize is open for competition to all the members of the medical profession in the United Kingdom. The end of February, 1903, is the limit of time by which essays competing for the prize must be sent in.

THE Liebig Company, we are told, have given away during the past month a quarter of a million of cookery books, including one to the household of every member of the medical profession. Should any of our readers not have received a copy, they ask us to state that one will be sent free on receipt of name and address at their office, 9, Fenchurch Avenue, London. The Lemco cookery book is a neat little volume compiled by a well-known authority, and embraces 180 original recipes for soups, fish, entrées, invalid cuisine and general cookery. Many housewives will doubtless be grateful that the enterprise of the Liebig Company has provided them with so useful a guide to the culinary art.

MR. F. J. GANT, F.R.C.S., whose works on "Surgery," in a past generation, will be favourably remembered by many, now devotes the leisure of his retirement to literature of a non-medical character. We have before us his latest contribution, entitled "Modern Natural Theology" (published by Elliot Stock), in which, whilst firmly holding the necessity of evolution he quite as firmly and surely believes in a Creator and a God, and in which he can venture to say, from his own convictions, founded upon anxious and serious inquiry, "evolution is not the grave of natural theology, but its ever living and most majestic expression." The chapter on "The testimony of man's moral nature to a Supreme Moral Lawgiver" is well worthy of reflection. The author has got at the heart of things when he says "Man never finds unalloyed happiness in being his own master."

THOSE of our readers who enjoy a highly-spiced and amusing story should read "The Persecution of John P. Tadcaster," by Max Adeler, published in the March number of *The Leisure Hour*, by the R. T. Society. It is an account of a man who becomes an amateur doctor by force of circumstances, in spite of his own protestations, and who eventually receives a large legacy under the will of a grateful patient. This gentleman was travelling for the purpose of study in no way connected with the medical profession; he carried with him, as

was his habit, some quinine pills, paregoric, and court plaster, in case of need. With this simple armamentaria he cured children and adults of fevers, broken legs, &c., instant, and even raised the dead to life on one occasion. But the story is too good to give away its points. *The Leisure Hour* is at all times one of the most instructive of the magazines, and this number will particularly commend itself to the profession.

An interesting little book at the present juncture, entitled "The Fish River Bush, South Africa," by W. T. Black, M.R.C.S., L.S.A., has just been published by Mr. Pentland. It is a reprint of articles contributed to the *Edinburgh New Philosophical Journal* by the author when he was serving as Army Surgeon on the Fish River in the Kaffir wars of 1848 and 1852, and will be appreciated by colonists of the present day in view of the changes that have taken place since the contributions were first penned. The wild animals mentioned by the author include "elephants and hippopotami, tigers and hyenas, koodos and bush-buck," and in his preface he suggests that they will have disappeared by now. The hippo no longer sports in the Fish River, and the elephants have shifted west to the Addo Bush; but koodos, tigers (leopards), and bush-buck remain, together with the wild birds he found in such numbers fifty years ago.

Medical News.

A Libel Action against a Medical Man.

DR. G. W. GRAHAM, of Mathyness, Witham, defended, last week, an action for libel brought against him by his former housekeeper. The libel was contained in a letter addressed by the defendant to the husband of the plaintiff in the form of an accusation of systematic dishonesty. A verdict was given for the plaintiff for £65 with costs.

The Sale of Insecticide.

MESSES. JENKINSON, of Newcastle-on-Tyne, horticulturists, were last week fined £2 and costs for having sold a certain poisonous insecticide without labelling it poison. The insecticide in question was shown to contain a large proportion of nicotine, and it was put into an old brandy bottle without a label, with the result that a gardener drank some of it and died. It was urged for the defence that the law only applied to substances or preparations intended for therapeutical uses because, if otherwise, paint which contained lead or arsenic, would require to be labelled poison, indeed quite a large number of substances would require to be so labelled were the contention of the prosecution adopted. Fortunately this ingenious argument did not carry weight with the bench, and if the result should be to render the use of the poison label more general so much the better.

The Mortality in Foreign Cities.

ACCORDING to official returns supplied to the Registrar-General, the death-rate of the various populations per thousand for the latest week to hand were: In Calcutta 36, Bombay 94, Madras 48, Paris 27, Brussels 17, Amsterdam 18, Copenhagen 17, Stockholm 16, Christiania 12, St. Petersburg 25, Moscow 25, Hamburg 15, Munich 19, Vienna 20, Prague 24, Buda-Pesth 19, Trieste 23, Rome 19, Venice 31, New York (including Brooklyn) 21, Philadelphia 21.

Portrait of the late Dr. Leech.

A PORTRAIT of the late Dr. Leech, painted for the Leech Memorial Fund by Mr. George Harcourt, was presented last week to the Council of Owens College.

St. Thomas's Hospital.

THE following house appointments have been made:—House Physicians.—T. B. Henderson, M.A., M.B., B.Ch., Oxon.; H. S. Stannus, L.R.C.P., M.R.C.S.; W. M. G. Glanville, M.A., M.B. B.Ch., Oxon. (Extension); T. W. S. Paterson, M.A., M.B., B.C., Cantab., L.R.C.P., M.R.C.S. (Extension).

Assistant House Physicians.—H. W. Sinclair, M.B. Lond., L.R.C.P., M.R.C.S.; K. E. Crompton, B.A., M.B., B.C., Cantab.

House Surgeons.—G. A. C. Shipman, M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S.; W. Hill, B.A., Cantab., L.R.C.P., M.R.C.S.; T. W. H. Downes, L.R.C.P., M.R.C.S.; F. J. Child, M.A., M.B., B.C., Cantab., L.R.C.P., M.R.C.S.

Assistant House Surgeons.—B. S. Jones, L.R.C.P., M.R.C.S., J. Coates, L.R.C.P., M.R.C.S., A. C. Hudson, M.A., M.B., B.C., Cantab., H. Spurrier, B.A., Cantab., L.R.C.P., M.R.C.S.

Obstetric House Physicians.—(Senior): V. S. Hodson, B.A., M.B., B.Ch. Oxon. (Junior): T. D. Miller, L.R.C.P., M.R.C.S.

Ophthalmic House Surgeons.—(Senior): F. B. Skerrett, B.Sc. Lond., L.R.C.P., M.R.C.S. (Junior): F. Clarkson, M.B., R.S., Durh.

Clinical Assistants in the Special Department for Diseases of the Throat, Skin, and Ear.—Throat: Z. Mennell, M.B. Lond., L.R.C.P., M.R.C.S., B. E. Sansom, L.R.C.P., M.R.C.S., L.S.A. Skin: H. A. Easton, L.R.C.P., M.R.C.S. Ear: H. S. D. Browne, B.A., Cantab., L.R.C.P., M.R.C.S.

Clinical Assistant in the Electrical Department.—L. S. Dudgeon, M.R.C.P., M.R.C.S. (Extension).

Conviction of a Medical Man.

JOHN FLANAGAN, L.R.C.P., L.R.C.S. Ed., was found guilty at the Assizes, held at Longford last week, of throwing vitriol over a groom. Flanagan pleaded guilty and was sentenced to twelve months' imprisonment from the day of arrest. A hope was held out by the Judge that if compensation was given to the injured groom the sentence would be reduced.

The "American Specialists."

THE American specialists were arraigned before the Lord Chief Justice at Ennis last week on a charge of obtaining money under false pretences. Evidence was given of the defendants having guaranteed cures in return for various sums of money, and also of the nature of the bottles of medicine, &c., which they dispensed. For the defence, four women were examined as to cures they stated were effected by the treatment of Madame Lillian. The jury were unable to agree, and his lordship said he would allow the defendants out, to appear on getting ten days' notice, on George Lillian's paying £23 to the Crown Solicitor, and entering into personal recognisances of £50; the two women should enter into personal recognisances in £10 each.

[An American Swindler.

Dr. W. J. SINCLAIR, of Manchester, has been the victim of a swindler who borrowed money from him on the representation that he was Dr. C. C. Perry, of New York. Inquiries led to the discovery that this representation was false and a warrant has been issued for his arrest.

Dublin Death Rate.

THE average annual death-rate represented by the deaths registered in the Dublin registration area for the week ending Saturday, March 1st, 1902, was 30.0 in every 1,000 of the population. Tuberculous disease caused 42 deaths. Respiratory diseases caused 73 deaths. Diseases of the circulatory system caused 14 deaths. The death-rate in the Lisburn Street district of the city was 41.6 in every thousand, and in the Peter Street district it reached 46.2 in every 1,000.

The Cure of Lupus.

THE Emperor of Austria has given £840 from his private purse for the foundation of an institute for the cure of lupus.

3 Royal Colleges of Physicians and Surgeons, Ireland.

JOHN O'DONOGHUE, L.R.C.P. & S.I., has passed a special examination for the Diploma in Public Health.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

AN EDINBURGH GRADUATE.—We have made inquiry and find that the book has been out of print for some time, but a new edition is now in the press.

DR. BYRON BRANWELL is thanked for his courtesy.

L.R.C.P. Lond., M.R.C.S.—If our correspondent will furnish fuller data it will afford us pleasure to give an opinion.

MR. BURTON.—In the case of sale of practice it is usual only to introduce the incoming to patients on whom the vendor is at the time in attendance, not on those who have ceased for the time or permanently to be his patients.

NOTIFICATION FEES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Can you tell me whether a Suburban Sanitary Authority can make a rule debarring a medical man getting his notification fee or fees unless applied for within six months, which I am told is done by two Councils in my neighbourhood? Why should I be required to send in an account at all when the law fixes the price? I am not required to send in my account to a coroner or law court, why, then, for a Council? My notification of the case should be ample notice for payment. If they wish to make a rule, why should they not discharge their liabilities at fixed periods determined by themselves?

I am, Sir, yours truly,

M.

[* No such rule could be enforced at law, and we see no reason for conforming thereto. In case of difficulty the threat of proceedings would probably secure immediate payment.—ED.]

ALLEGED FRAUDS ON A MEDICAL MAN.—A CAUTION.

We have been asked to draw attention to the doings of a man who calls himself "Dr. C. C. Perry," in order to put the members of the medical profession on their guard against him. It appears that on the 11th of last month Dr. W. Japp Sinclair, of Manchester, was visited by an American who represented himself to be Dr. C. C. Perry, of New York, and who delivered a message purporting to be from an old medical friend of Dr. Sinclair's. He also represented himself as a friend of several medical men in America with whom Dr. Sinclair is acquainted. He explained that having missed a friend he was financially inconvenienced for the moment, and he asked for the loan of a few pounds promising to return the money on his arrival in London. Dr. Sinclair parted with the sum asked for, but soon had reason to fear that he had been victimised. He then communicated with his medical friends in New York, with the result that all the man had said was found to be untrue. A warrant has been issued for "Dr. Perry's" arrest.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, MARCH 12th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Pathological Evening.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. C. Stewart: On the Organs of Respiration. Lecture II.

THURSDAY, MARCH 13th.

BRITISH GYNÆCOLOGICAL SOCIETY (30, Hanover Square, W.).—8 p.m.—Specimens will be shown by Mr. Furneaux Jordan and Mr. E. O'Callaghan, and short papers will be read by Mr. Freyer (introduced) on Stone in the Female Bladder, also by Dr. E. T. Collins.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m. Dr. F. T. Roberts: On the Comprehensive Study of Thoracic Phthisis. Lumsden Lecture I.

FRIDAY, MARCH 14th.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Mr. H. W. Page and Mrs. Payne and Poynton: Two Cases of Arthritis of the Knee. Dr. W. Hale White and Dr. Walter C. Pakes: A Case of Malignant Endocarditis giving Widall's Reaction. Sir Thomas Barlow, Bart., and Dr. H. Baty Shaw: Hypertrophic Cirrhosis of the Liver. Mr. A. E. Sears: Acute Paralytic Dilatation of the Stomach.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11, Chandos Street, W.).—4 p.m. Cases will be shown by Mr. Mayo Collier, Dr. McCall, and the President.—5 p.m. A Discussion on the Diagnosis and Treatment of Various Forms of Nerve Deafness: opened by Dr. Dundas Grant, continued by Dr. Greville MacDonald, Dr. Barclay Baron, and others.—7.30 p.m. Annual Dinner at the Café Royal.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi Terrace, W.C.).—7.30 p.m. Dr. J. E. Kaye: Scarlet Fever: How far Statistics prove or disprove the Utility of Hospital Isolation.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, London, W.).—8.30 p.m. Cases will be shown by Mr. Hartbridge and Messrs. Harman and Bradburne. Papers.—Mr. B. Lawford Knaggs: Symmetrical Concentric Changes of Choroid and

Retina in Four Cases of Unusually High Myopia. Mr. W. H. H. Jessop: Membranous Conjunctivitis, with cases. Mr. Sydney Stephenson: Diphtheria of the Conjunctiva.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8.30 p.m. Clinical Evening. Mr. Keetley, Mr. Edwards, Mr. McAdam Eccles, Dr. Ball, and Dr. Saunders will show Cases.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. C. Stewart: On the Organs of Respiration. Lecture III.

DUBLIN.

FRIDAY, MARCH 14th.

NATIONAL HOSPITAL FOR CONSUMPTION.—Annual Meeting, Royal College of Physicians, 4.30 p.m.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Obstetrics, College of Physicians, 8.30 p.m. Specimens:—The President: Uterus removed for Fibromyoma; (3) Malignant Tumours of both Ovaries. Dr. Glean: Uterus Removed by Retro-peritoneal Hysterectomy, showing Peculiar Venous Attachment. Dr. Flynn: Uterus Removed by Vaginal Hysterectomy; (2) Omental Tumour. Dr. Horne: Large Uterine Polypus; (2) Double Pyosalpinx. Paper:—Dr. Purefoy: Report of the Rotunda Hospital for the Year 1900-01. Dr. Hastings Tweedy: Observations on the First Stage of Labour. The Causal Relation of this Stage to Uterine Rupture.

Appointments.

AUSTEN, HAROLD, M.D., B.S., Lond., M.R.C.S., L.D.S., Eng., Lecturer on Materia Medica to the Royal Dental Hospital of London.

CALBY, J. W., L.R.C.P., Edin., M.R.C.S., Medical Officer of Health for the Biccail Sub-district of Selby, Yorkshire.

DRINKWATER, JAMES PRITCHETT, M.R.C.S., L.S.A., Medical Officer of Health to the Liangollen District Council.

FULCHER, G. F., M.B., M.S., Edin., Medical Officer of Health to the Chingford Urban District Council.

GRIERSON, J. T., M.B., B.Ch., Vict., City Hospital, Park Hill, Liverpool.

HUMPHRY, E., M.R.C.S., L.R.C.P., Edin., Medical Officer of Health for the City of Chichester.

MILLER, J., M.R.C.S., L.R.C.P., Lond., City Hospital, Fazakerley, Liverpool.

MILLER, J. W., M.B., Ch.B., Vict., D.P.H., Cantab., Assistant Medical Officer to the City of Liverpool Hospitals for Infectious Diseases.

NESBITT, C., M.D., B.U.I., Certifying Surgeon under the Factory Acts for the Handalstown District of the County of Antrim.

SOPER, G. MORRIS, M.R.C.S., L.R.C.P., Assistant House Surgeon to the Royal Albert Hospital and Eye Infirmary, Devonport.

SWORDE, E. G., M.B., B.C., Cantab., Honorary Medical Officer to the St. Andrew's Convalescent Home, Folkestone.

Vacancies.

Bradford Royal Infirmary.—Dispensary Surgeon. Salary £100 per annum, with board and residence. Applications to William Maw, Secretary.

Children's Hospital, Forest House, Nottingham.—House Surgeon, Salary £100, with board and residence. Applications to Mr. A. F. Kirby, St. Peter's Church Walk, Nottingham.

Co. Mayo.—Qualified Medical Assistant. Applications to Dr. Crean, Ballyhaunis, Co. Mayo. (See Advt.)

East Sussex County Asylum, Hayward's Heath.—Second Assistant Medical Officer and Pathologist. Salary £175 per annum, with board, lodging, washing, and attendance. Applications immediately to the Medical Superintendent.

Essex and Colchester General Hospital.—House Surgeon. Salary £100 a year, with board, washing, and residence in the Hospital. Applications to C. L. Becher, Secretary.

Fisherton Asylum.—Assistant Medical Officer. Salary commencing at £150 per annum, with board, lodging, and washing. Apply to Dr. Finch, Salisbury.

Grey's Hospital, Pietersmaritzburg, Natal, South Africa.—Resident Medical Superintendent. Salary £350 first year. Board, lodging, and washing. First-class passage will be provided. Applications to the Agent-General for Natal, 26, Victoria Street, Westminster, S.W.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications immediately to the Medical Superintendent.

London County Asylum, Bexley.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Immediate applications to R. W. Partridge, Esq. (See Advt.)

Manchester Royal Infirmary.—Honorary Assistant Physician. Applications to W. L. Saunders, General Superintendent and Secretary. (See Advt.)

West Riding Asylum, Wadale, near Sheffield.—Fifth Assistant Medical Officer. Salary commencing at £140 per annum with board, &c. Applications immediately to the Medical Superintendent.

Births.

GEDGE.—On March 4th, at Pewsey, Wilts, the wife of Arthur Sydney Gedge, M.R.C.S. and L.R.C.P., of a daughter.

SAUER.—On March 5th, at 84, Westbourne Terrace, Hyde Park, London, W., the wife of Dr. Hans Sauer, of a son.

Deaths.

DUDLEY.—On March 7th, at 149, Cromwell Road, London, S.W., William Lewis Dudley, M.D., F.R.C.S., Eng., in his 62nd year.

The Medical Press and Circular.

Original Communications.

A CASE OF

COMPLETE CONSOLIDATION OF THE LEFT LUNG

WHICH PRESENTED GREAT DIAGNOSTIC DIFFICULTIES. (a)

By, BYROM BRAMWELL, M.D., F.R.C.P.,
F.R.S.E.,

Physician to the Edinburgh Royal Infirmary, &c.

THE patient, a married man, æt. 57, a cellar-man by occupation, was admitted to the Edinburgh Royal Infirmary on January 28th, 1902, complaining of great shortness of breath on exertion, debility, hoarseness of voice and troublesome cough, and some pain in the left hypochondriac and infra-axillary regions.

The illness had commenced seven months previously. There had been very little expectoration, but the patient had lost weight and had had some sweating at night. At first he denied syphilis, but subsequently admitted that he had had a hard chancre followed by secondary symptoms eight years ago. When thirty-seven years of age (twenty years ago) he had had rheumatic fever. For the past twenty years he had occasionally suffered from sciatica and from what he termed rheumatic pains in the legs. These pains do not appear to have been lightning pains.

On admission he was found to be very debilitated and considerably emaciated (height, 5 ft. 5½ ins.; weight, 9 st. 7 lbs.); the temperature was 99° 2'; the pulse, 96. He was not anæmic and did not look cachectic; there was some cyanosis of the face and lips.

The whole of the left chest from top to bottom was dull on percussion. At the base of the left lung the dullness was less absolute than one would expect in a case of pleuritic effusion, and hypodermic exploration showed that there was no fluid. Over the greater part of the left lung loud bronchial breathing, the expiratory sound being particularly well-marked, and increased vocal resonance were present. There were no moist sounds over any part of the left lung. The dullness was clearly due to consolidation of the lung. At the level of the nipple the left chest measured half-an-inch more than the right (18½ and 18¼ respectively).

There was some impairment of the percussion note between the right scapula and the spine, and over this area and all down the right side of the spinal column a systolic murmur was audible. Indistinct pulsation could be felt in the second and third left

interspaces close to the sternum. Over the manubrium sterni and in the second and third interspaces, both right and left, a systolic murmur and accentuated aortic second sound were audible; the murmur and accentuation were much louder in the second and third left interspaces than on the corresponding point on the right side. Loud, blowing tubular breathing was audible over the manubrium sterni, and especially under the left sterno-clavicular articulation.

The heart appeared to be of normal size; the mitral sounds were normal. The radial arteries were thickened and somewhat atherosed. The left radial pulse was somewhat smaller and the apex of the upstroke in the sphygmographic tracing less sharp than that of the right.

The veins in both upper extremities and on both sides of the neck, but especially on the left side of the neck and on the left arm, were somewhat engorged.

The left vocal cord was fixed and immobile. There was no difficulty in swallowing. The pupils were contracted and usually equal (three millimetres in size), but occasionally the left pupil was much more contracted (two millimetres). No tracheal tugging could be detected. The contraction of the pupils to light was somewhat sluggish. There were no enlarged glands either in the neck or axillæ.

The red corpuscles were slightly reduced in number, normal appearance; the white corpuscles numbered 28,000 per cubic millimetre, i.e., marked leucocytosis was present.

The deep reflexes were altered in a very interesting way. The right knee-jerk was active, the left absent even after reinforcement; both Achilles-jerks were absent. This condition of the reflexes was highly suggestive of previous syphilis, and on cross-examining the patient he admitted (though he had previously denied it) that eight years previously he had a hard chancre followed by secondary symptoms.

The X-ray examination gave no definite information. The picture which was obtained, both on the screen and in the photographic negative, was very indistinct. It showed complete consolidation of the left lung, and some opacity to the right of the spinal column, between the right scapula and the middle line, and below this point to the base of the right chest. Mr. Dawson Turner who made the examination could give no opinion as to the nature of the lung consolidation, or as to the presence or absence of an aneurysm.

The diagnosis was extremely difficult. The dullness was clearly due to consolidation of the lung; there did not appear to be any fluid in the pleural cavity. Most of the competent observers who had examined the case were of opinion that the consolidation was due to malignant disease of the lung and mediastinal glands. Dr. Bramwell found it very

(a) Read at meeting of Edinburgh Medico-Chirurgical Society March 5th, 1902.

difficult to accept this opinion. He had never seen such extensive consolidation the result of malignant disease of the lung without much more cachexia and anæmia. Dr. Bramwell thought that the consolidation of the left lung was probably due to aneurysmal pressure on its root. There was certainly arterial and aortic disease. The patient had had syphilis and the condition of the reflexes was suggestive of a post-syphilitic lesion. The absence of anæmia and cachexia and of any glandular enlargement at the root of the neck was against malignant disease. On the other hand, the absence of tracheal tugging and of difficulty in swallowing was against aneurysm. The paralysis of the left vocal cord, the difference in the pulses and pupils were rather in favour of aneurysm, though they might of course be due to a mediastinal new growth. It was difficult to reconcile the greater measurement of the left chest (half an inch more than the right) with aneurysmal pressure on the left bronchus and resulting consolidation of the lung. In other cases of this kind which had come under Dr. Bramwell's notice, the left lung had always been more or less collapsed. The leucocytosis was at first sight strongly in favour of a new growth, for leucocytosis is usually a marked feature in malignant disease of the lung, but it is not present in uncomplicated cases of thoracic aneurysm. Dr. Bramwell was, however, of opinion that the leucocytosis could quite well be accounted for by the condition of the lung, granting that the consolidation was the result of aneurysmal pressure on the root. He had seen, either during life or in the post-mortem room, several cases in which consolidation of the left lung had been produced in this way; in some cases the lung had been completely solidified, and catarrhal and inflammatory changes, in one case going on to gangrene, had developed in it. Such a condition of the lung would account for the leucocytosis. The point was of considerable diagnostic interest; so far as he knew there were no recorded observations regarding it—the condition of the blood in aneurysm with consolidation of the left lung due to pressure on the root.

The course of the case during the time that the patient had been under treatment (rest and iodide of potassium) was, Dr. Bramwell thought, in favour of an aneurysm rather than of a new growth. In the course of five weeks the patient had gained 7½ lbs. in weight, the leucocytes had dropped from 28,000 to 9,800 per cubic millimetre (the red corpuscles now numbered 4,300,000, and the hæmoglobin equalled 75 per cent.); the pain in the left side had disappeared, the dyspnoea was rather less, and the patient had gained strength. The pulse had remained quick (average about 100), the temperature was usually normal, though occasionally somewhat elevated; there had been very little expectoration. During the past three or four days the patient had spat a small quantity of thick, tenacious, dark-brown sputum. Microscopical examination of the sputum showed numerous large cells with well-marked nuclei; many of the cells contained pigment particles derived from the lung, others fatty granules. The character of the cells was not distinctive; they might be merely swollen catarrhal cells derived from the bronchi or air cells; they might be derived from a new growth (carcinoma or large-celled sarcoma); the pigmented character of some of the cells was, perhaps, in favour of the former view.

Taking the whole of the facts of the case into consideration, and after carefully weighing the evidence, Dr. Bramwell adhered to the opinion which he had formed when he first saw the case; he thought that the consolidation of the lung was probably due to aneurysmal pressure on its root; but he admitted that the diagnosis presented great

difficulty. If, as others who had seen the case supposed, the consolidation of the lung was due to the presence of a new growth, there certainly seemed to be arterial (aortic) disease as well. It might be suggested that the consolidation of the lung was due to a syphilitic lesion, but the fact that the whole lung was involved rendered this supposition extremely unlikely.

PATH AND MODE OF INFECTION.

By DR. L. HUISMANS,

Oberarzt, Cologne.

THE following remarks have for basis a case of pyæmia which came under my notice some time ago, from which I have made a few preparations to illustrate my object in carrying out my investigations of the cause of the pyæmia and the channel through which it found access to the body. I shall venture to preface my remarks with the hope that clinical facts will meet with more favour than they have done of late since the introduction of bacteriology as the guiding star of all our efforts at diagnosis and treatment. Modern thought is now running riot with our reason, and decentralisation leading to an erroneous specialisation of bacterial results which are not unfrequently very contradictory to bedside observations, which have recently been almost lost sight of.

My own recent researches have been confined to the properties of the pyogenic microbe, and I believe that its introduction acts on a centre that produces heterogeneous morbid phenomena. The following example may be of interest.

Mr. S. was brought to hospital on the evening of March 5th, 1900, with a temperature of 39·6°, which fell to 37·7° C. in the morning—pulse 96. The heart was normal; in the left pleura an effusion which extended to the middle of the scapula; otherwise the lungs were healthy. Over the left spina scapulæ was a small crucial incision from which serous fluid escaped. This the patient said was made for the relief of a painful carbuncle which had formed on this site six weeks previous to his admission. In the right eye there was marked oedema of the bulbar conjunctiva, the pupil was moderately dilated and did not react to light, while on the anterior surface of the lens there was a white exudation. Nothing abnormal was found in the left eye. In the right knee there was a very painful swelling. The urine had neither albumin nor sugar. On the following evening the temperature rose again to 39·8° C. (103·7° F.). An exploratory puncture was made into the chest, from which exuded a serous fluid tinged with blood.

This confirmed the diagnosis of pyæmia with abscess in the right eye and knee, and it was thought that the serous fluid in the pleura was the prodroma to empyema just as meningitis serosa often becomes purulent. In this case, however, the origin may be attributed to the painless, slow-healing carbuncle.

The prognosis was bad, and, as expected, the patient died suddenly the following night.

The post-mortem examination revealed an abscess in the vitreous exudation on the anterior surface of the lens, suppuration in the right knee around the femur, which had burst into the joint. After removing the sternum, the cavity of the pleura was found to be full of serous blood-stained fluid mixed with large black clots. It is presumed that severe hæmorrhage occurred during the night and killed the patient. In the upper part of the right lung there were adhesions. In the pericardial cavity there was serous fluid, but the pericardium itself was unchanged. Heart tissue was also healthy, although there was a little atheroma in the aortic valve. The

mediastinum in the region of the arch of the aorta was free. The aorta from the heart to the diaphragm was regularly cylindrical, measuring 85 to 95 mm., or 3·34 ins. in circumference, and was highly atheromatous. About three centimetres above the point where it passes through the diaphragm a fresh red thrombus extended up the aorta 10 cms. At this part the aorta, pleura and mediastinum were soldered together. Beneath the thrombus there was softening of the arterial wall, with a perforation as large as a sixpence, the edges being ragged. The pathological section shows a hæmorrhagic infarct in the lung, with union of pleura and fibrinous clots. No other inflammation existed.

This was evidently an inflammatory embolus which had become impacted in the arterio-pulmonalis, which later produced a hæmorrhagic infarct. The virulent embolus which was associated with the aortic atheroma had not had time to form a pulmonary abscess with empyema, although the complications of pleuritis serosa, adhesion of the mediastinum, and softening of the aorta hastened the termination, as the perforation allowed a flow of blood into the left pleura, which was the immediate cause of death.

It may be noted here that the blood in the aspirated fluid was a premonitory sign of the result, as this frequently occurs in the sputum before the bursting of an aneurysm of the arch of the aorta.

The remoteness of the pyæmia is another important point which cannot be better illustrated than by quoting from my "Contributions to the Knowledge of Septic Diseases," where I relate a case of pyæmia and death after a bite on the thumb which healed up perfectly. About fifteen days after healing the patient began to complain of pain in the left axilla with swelling of the glands and high fever. This was rapidly followed by peritonitis, pleuritis, pericarditis, and nephritis of a month's duration. The post-mortem revealed a mass of streptococci in the axillary glands.

Lippmann, of Berlin, relates another interesting case bearing on this subject in his "Rückfalle." In the case of a child who had scarlatina a number of glandular swellings were left about the maxillary angles. Some time after, the child was taken suddenly ill without any apparent cause; the temperature rose, the throat became sore, and another attack of scarlet fever developed, and immediately the whole of the swollen glands disappeared. He affirms that years may elapse before the latent glands explode, and he relates others, from five months up to three years, with nephritis, otitis, &c. In this case there seem to be three factors to reckon with, viz., phagocytosis, the formation of antitoxin, and *glandular interception*. On this subject Arnold, of Heidelberg, seems to found his "Staub-inhalation und Staub-metastase," and terms the glands "filter absolut sufficiente." In 1886, Arnold commenced his treatment. This consisted of carbon in fine powder obtained from condensing the smoke of turpentine. This was inhaled and was supposed to enter the retro-bronchial glands and to play a part in the lymph sinus. This he found never passed into the blood unless caseous degeneration of the gland occurred, or when ulceration and atrophy with emphysema were present. The same analogy might be applied to the bacteria if the toxin be excluded.

Moreover, Ribbert and Landerer, in their "Teleology," go further into the functions of the lymphatics, whose sinus they maintain is wholly governed by the follicle. This is the "battle field" of the bacteria and the leucocytes and the follicles, the rampart wall which the bacteria have to storm before they can lead the force into the citadel. When the attack commences the spinal centre is apprised of the danger, and immediately leads into the field an army

of leucocytes which, when overpowered, cease resistance, and the conqueror takes possession. If, however, the circumvallation can be restored before the whole army passes into the circulation the invaders may be totally annihilated, while the approaching enemy is again defied and held without the fortress, but entangled in the meshes of the gland, where they may lie in ambush waiting an unguarded opportunity when a rush can be made with ultimate success. Ribbert and Landerer record one of these ambush adventures to have lasted thirty years in the case of a patient with osteomyelitis acuta! This form of ambush is considered very common in tuberculosis, where attacks alternate with resistance extending over years. I well remember a case of my own, G., who three weeks after being discharged from hospital cured of typhoid, came back with a high temperature, which was followed by periostitis tibialis et ulnaris with doughy infiltration of the surrounding muscles. After this had passed away the left testicle began to swell, and formed a large abscess.

Dressmann relates several similar cases, one resembling Ribbert's, in that a typhoid attack was followed by periostitis, &c., but in all his observations no enlargement of the spleen occurred.

Leichtenstern endeavours to show that the nephritis of scarlatina is due to the same cause though this has been objected to by casuists as being too obvious. Leichtenstern thinks this is due to the active muscular movement which assists the lymphatic vessels in carrying the poison from the skin to the lymphatic glands in greater quantity, this passing into the circulation and being finally eliminated by the kidneys. Leichtenstern overlooks the fact that the toxin is the cause of the nephritis, while the bacteria are held back in the gland, and may make a renewed attack at a later period. Hence the reason of Denig's admonition that fever patients are not kept sufficiently long in bed to overcome the sepsis of the disease which blazes up at the slightest provocation. There is another point that should not be forgotten, viz., that even in typhoid fever a few virulent bacteria have been found in the urine after the attack is over, which proves that all the microbes are not retained by the glands as proved by Neufeld.

It has already been stated that the deposit of infectious material is retained during a period of latency in the gland. This may occur in more remote tissues, such as cysts. Wallgren tells us of a typhoid patient with an ovarian cyst, who three months after recovery was taken very ill with high fever and great pain, necessitating operation on the cyst, which was found to contain 1½ litres of a yellow greenish fluid from which cultures were made that agreed in every particular with Widal's typhoid bacillus. The cyst wall was infiltrated with these microbes. It may therefore be easily perceived how a slight injury to such a cyst would provoke a new attack by liberating the latent germs.

The different forms of infection as well as their different modes of transmission may here be briefly referred to. It is now acknowledged that anthrax and tuberculosis are not found operating at the same time and place, although septic infection is not uncommonly present to modify the clinical course of the disease. This is well illustrated in slight cases of angina where the streptococci may be present, but whether the disease will be severe septic-pyæmia scarlatina or erysipelas, no one can forecast till the fever is well advanced. The question arises, has the serous membrane any effect in the spread of the disease? In polyarthritides rheumatica, as in scarlet fever, we have an arthritis serosa. From this it would appear that scarlatina-arthritis is the severe form, because it more frequently passes on to the pyæmic form. Another peculiarity of the scarla-

tina infection is its proneness to pass over to the puerperal state; but as both forms of scarlatina are due to a streptococcus, it is more readily taken up. The same thing may be seen in the frequency of furunculosis in scarlatina with remitting fever in which is to be found a streptococcic pneumonia. The streptococcus of erysipelas differs from the streptococcus of dermatitis scarlatina, so far as it locates itself in a particular region of the cutis, but the exfoliation is exactly the same. Carrying the resemblance still further, we find that the nodules around the margin of an active centre of erysipelas is analogous to erythema nodosum, or petechiæ in septicæmia and purpura rheumatica.

Another important question arising in connection with these septic diseases is immunity. Will the same antitoxin produce immunity in all these diseases with apparently the same microbe in spite of clinical differences? or will a different toxin be required? The list of authors is long who affirm with confidence that septic disorders of the blood, scarlatina, polyarthritis rheumatica, and pyæmia have the same microbic and pathological origin. In support of this view many have contributed irresistible facts. Michael had six cases of rheumatic endocarditis which gave diplococci under the microscope, but on cultivation produced streptococci; Wusserman gives cases of chorea post-rheumatic, with streptococci on valves which when injected in dogs produced articular inflammations, and when cultivated produced genuine streptococci. The absence of bacteria in the synovial fluid of inflamed joints is no proof of their absence; in pleuritis serosa or hæmorrhagic tuberculosis no bacteria can be discovered, but if injected into animals they may produce typical tuberculosis.

Baginski and Sommesfeld have attempted to classify these septic infections into three divisions—severe, moderate, and slight, but the protean forms that clinically appear weaken the utility of such classifications in practice. Under "severe," where the kidney was involved, they would place pyæmia sepsis and septicopyæmia. The moderate group would embrace those with cloudy swelling of kidney coming late, as erysipelas, scarlatina, and polyarthritis rheumatica. The light form would rarely involve the renal organs, such as furunculosa purpura, rheumatica erythema nodosum, rheumatismus musculorum, and chorea post-rheumatica.

From the variety of opinions advanced the critic is apt to become sceptical, and exclaim that bacteria are to be found as geologists find fossils in the different strata and are only indications of some remote past.

Therapeutic Notes.

By GEORGE FOY, M.D., F.R.C.S.,
Surgeon to the Drumcondra Hospital, Dublin.

OIL OF CAJUPUT.

EVERY physician has on his list a number of cases of winter cough. His patients are advanced in life, and for some years past have had, during the cold months, night cough, with an abundance of mucopurulent phlegm and embarrassed respiration. From 3 a.m. to 5 a.m. they sit up in bed coughing and expelling the tough mucus, they can hardly get their breath, and they complain of a pain in the region of the heart, which in the great majority of these cases is weak from degenerative changes, and sometimes dilated. To make matters worse the patients as a rule suffer from flatulent dyspepsia. The heart is greatly laboured, and calls for some powerful stimulant to rouse the right ventricle into action and pro-

duce a firm, strong contraction; under such conditions cajuput will be found a valuable addition to the chloride of ammonium and strychnine mixture. It consists principally of cincol or eucalyptol, and consequently is a valuable alimentary antiseptic, checking the decomposition of food in the stomach and from its stimulating effects on the muscle tissue, producing contraction of the viscus and eructation of wind. The drug is freely eliminated by the lungs, and after a five minim dose the characteristic camphoraceous smell of the oil is detected for a considerable time in the breath of the patient. In bronchorrhœa, where the sputum is offensive, the antiseptic action of the cajuput is soon manifest. Unlike many drugs of its class it does not irritate the kidneys.

It has, however, one drawback—patients after a few weeks take a distinct distaste to it. By giving tincture of nucis vomica or liquor strychnia as a tonic separate from the expectorants the nausea and loss of appetite which they produce may be averted and the bitterness of the strychnia may act as fillip to the appetite.

Cajuput has the advantage of being therapeutically compatible with all our best known stimulating expectorants. Its camphoraceous taste, which many patients dislike, is best concealed by adding it to a paste of liquorice powder and honey; this can be rubbed up with chloroform water, when it forms a not unpleasant mixture. For ordinary bronchial attacks the drug is unsuited, but for cases in which its use is indicated its effects are prompt and the relief it affords very great. When in pneumonia the heart is over-taxed and threatens to stop cajuput is a valuable restorative, and a trustworthy therapeutic agent.

DYMAL.

DYMAL, a salicylate of didyme, is one of the latest antiseptics claiming consideration. It occurs as a light, very fine, inodorous powder. Mixed with lanoline in the proportions of one part to ten, it forms an excellent ointment for the treatment of burns of the second and third degree, lessening the pain, diminishing the secretion, and promoting healthy granulation.

For minor surgical operations it makes a good dusting powder, with well-marked antiseptic and dessicant properties, and it has the advantages of being non-toxic and non-irritant.

The ointment produces very good results in acute vesicular eczema, though, in chronic forms of the disease, and in scaly eruptions generally, it seems to have little effect.

BLENNORRAGIA.

For the prophylaxis of blennorrhagia, Stakel, of Vienna, recommends the use of salol to the interior of the neck of the womb, or that it be painted with a small quantity of camphor-salol. He also used an ointment consisting of protargol one part, vaseline nine parts. It is introduced to the mouth of the womb in a fine collapsible tube, and the required amount pressed out so as to smear the internal surface of the neck.

The Mortality in Foreign Cities.

ACCORDING to official returns supplied to the Registrar-General, the death-rate of the various populations per thousand for the latest week to hand were: In Calcutta 39, Bombay 101, Madras 54, Paris 27, Brussels 14, Amsterdam 15, Stockholm 18, Christiania 16, St. Petersburg 23, Moscow 28, Hamburg 16, Munich 19, Vienna 20, Prague 24, Buda-Pesth 16, Trieste 24, Rome 21, Venice 25, Cairo (8 days) 29, Alexandria (8 days) 34, New York (including Brooklyn) 21.

The Hunterian Lectures ON THE ANATOMY, PHYSIOLOGY AND PATHOLOGY OF THE IMPERFECTLY DESCENDED TESTIS. (a)

By W. McADAM ECCLES, M.S.LOND.,
F.R.C.S.,

Hunterian Professor of Surgery; Senior Assistant Surgeon, West London Hospital; Assistant Surgeon, City of London Truss Society; Examiner in Anatomy to the Society of Apothecaries, &c.

ABSTRACT OF LECTURE III.

PATHOLOGY—(continued).

CYSTS OF THE IMPERFECTLY DESCENDED TESTIS.

MR. PRESIDENT AND GENTLEMEN,—There are at least four varieties of cysts that may be developed in connection with the testis that has failed to reach the scrotum. These are: (1) cysts formed upon the epididymis; (2) cysts found in the testis proper; (3) cysts due to foetal remains; and (4) dermoid cysts, teratomata. 1. Cysts in connection with the epididymis.—Like the cysts derived from the epididymis of the fully descended organ, so those found associated with the arrested gland are of two varieties, the small and the large. In the former the cysts never tend to enlarge to any but a comparatively small size, certainly not greater than that of an ordinary cob-nut. They are not therefore of much clinical importance. In the latter there is a tendency for the cysts to grow and they may assume such proportions as to become of very definite clinical significance.

2. Cysts in connection with the testis proper.—That the tissue forming the testis proper can originate cysts is a fact that is well recognised. They have been for the most part designated simple cysts or cystic fibroma of the testis. They are found in connection with the imperfectly descended testis as well as in that organ which has reached the scrotum. They are, perhaps, more usually seen in the lower animals than in the human subject.

3. Cysts in connection with foetal remains.—Attention has been already drawn to the fact that cysts in connection with the imperfectly descended testis are derived from the dilatation of certain foetal remains, and perhaps more frequently so in the arrested testis than in the one that has fully descended. They are extremely interesting, and may be classified as follows: Those derived (a) from the hydatid of Morgagni; (b) from the Wolffian tubules; (c) from the vasa aberrantia; and (d) from the paradidymis. These cysts vary much in their characters. One which was found in the abdomen of a sheep, considered before death to be of the female sex, occupied the pelvis. Another cyst that I have examined was formed from the left testis which was removed from the abdomen of a horse, aged two years.

4. So-called dermoid cysts of the testis that have reached the scrotum have been undeniably observed, although it is no doubt true that some of the specimens that have been recorded are more likely to have been dermoids derived from the scrotal tissues rather than from the testicular body. I have not been able to trace a record of a true dermoid cyst of an imperfectly descended testis in the human subject, but there are several recorded in animals, and particularly in the horse. In these latter animals they have been shown to present similar characters to the common dermoids found in the human ovary, and probably their origin is somewhat the same.

MALIGNANT NEW GROWTHS OF THE IMPERFECTLY DESCENDED TESTIS.—Both sarcoma and carcinoma may attack an imperfectly descended testis, but the mesoblastic neoplasm seems to be of rather more frequent occurrence than the epiblastic. Sarcoma of a testis, whether of the fully descended or the partially migrated organ, is a comparatively rare disease. Considering that

every male, except an infinitesimal minority, has at birth two testes, wherever they may be situated, it follows that the number of testes that might become the seat of a new growth of a malignant character is enormous, yet the instances of such lesions admitted into large hospitals is decidedly small. From the published statistics of one hospital at which over 4,000 males are annually admitted there were only thirty-eight cases of sarcoma of the testis, whether fully or imperfectly descended, seen in fifteen years, giving an average of two and a-half cases a year. It is a matter of extreme difficulty to determine satisfactorily whether a testis that has not reached the scrotum or has passed into an abnormal position is proportionally more liable to become attacked with sarcoma than one which is situated in its usual place. In the thirty-eight cases which have just been alluded to only one was in a testis which was imperfectly descended, the gland lying in the abdomen and belonging to the left side. In a close examination of 48,000 males with hernia, 854 had imperfect descent of one or both testes, or one in every fifty-six, and none of these presented any form of malignant disease of the testis, though many had had attacks of inflammation of the testis, and in some instances these had been often repeated. The forms of sarcoma that affect the testis when it is retained are similar to those that occur in the normally placed gland, although there are not, so far as I have been able to determine, instances of every variety. The varieties as a rule met with are: the round-celled, whether chiefly of large or small cells, the spindle-celled, the mixed-celled, and the myxo-sarcoma. No instance of cartilage being present with the sarcomatous elements in a testis which has not reached the scrotum is on record. This is a matter of some interest seeing that cartilage is comparatively frequently found in the spindle-celled sarcoma of the fully-descended organ.

The disease begins most usually between the ages of 20 and 40 years, and it is therefore a disease rather of middle life. Sarcoma of the fully descended gland is not uncommon in quite young boys. There does not seem to be any marked difference as to which side the new growth attacks. This is not altogether in accord with the fact that the right testis is the one that is most frequently the seat of arrest. Inguinal inclusion is the most common place for the arrested testis to be found, and thus it is the general position in which sarcomatous imperfectly descended testes are discovered. After this position the abdominal retention is the next most productive of a malignant new growth, which again is of interest from the fact that abdominal inclusion is not the second most common position for the testis to be found, just below the superficial abdominal ring being more usual.

A definite history of an injury, such as a blow, a squeeze, &c., is not infrequently given in the cases where sarcoma attacks the testis lying in the scrotum, but when the lesion affects the imperfectly descended testis a predisposing cause of this nature is not nearly so common or so clear. On the other hand, it must be remembered that the testis which lies in the inguinal canal is subjected to numberless though probably slight occasions of violence, which may pass in the greater number of instances without any notice being taken of them.

An associated hernia is such a common complication of an imperfectly descended testis that caution must be used in considering that it has any influence on the production of malignant disease, though this has been much asserted by some observers. In the 854 instances of arrest of the testis accompanied by hernia which have been already mentioned in no single instance was a sarcomatous growth also present. Further, out of twenty-six cases of sarcoma of the imperfectly descended testis only two had a hernia associated with the new growth, and in neither of these did the protrusion seem to have any bearing whatever on the production of the neoplasm.

It is well recognised that vestigial elements in imperfectly developed organs are peculiarly liable to give origin to malignant growths. As was shown in the first lecture, the examination of testes which have failed to reach the scrotum reveals in most of the instances two

(a) Delivered before the Royal College of Surgeons of England on Feb. 28th, 1902.

distinct abnormalities. First, the seminiferous tubules are atrophic or undeveloped and present no signs of spermatogenesis; and secondly, there is a distinct increase in the interstitial cellular elements. It is open to question whether these latter cells, which appear in so much larger numbers than they do in normally placed testes, have an epithelial or mesoblastic origin. If epithelial, then they may be the remains of the lining of aborted seminiferous tubes; if mesoblastic, probably they are the remnants of the Wolffian body. Although there does not at present seem to be sufficient evidence to definitely determine their source, yet on the whole it would appear that they owe their existence to mesoblastic rather than to epiblastic tissue. The cells, moreover, are somewhat like those of the adrenal, particularly the cortex of this structure, but it is doubtful whether they can be taken as the remains of such. As has been stated, the majority of malignant growths of the testis which have been arrested are of a sarcomatous nature, and the occurrence of these interstitial cells may therefore be an explanation of this frequency.

While it has already been noticed that carcinoma of the imperfectly descended testis is less common than sarcoma of the gland, yet it is probable that this is even more distinctly so from the fact that many of the cases which have been recorded as "cancer," "encephaloid," or "medullary" disease by the older writers were in reality examples of sarcoma rather than of carcinoma. The most probable source of the cells, and, therefore, the growth of which they form the chief part, is from the imperfectly formed epithelial elements of the seminal tubules. Another reason why carcinoma of the arrested testis is comparatively uncommon may be found in the fact that there is so little active epithelium present in the poorly developed organ.

While sarcoma of the arrested testis occurs most usually between the ages of 20 and 40 years carcinoma is, on the whole, a disease of rather later life—namely, between the ages of 30 and 50 years. The two sides of the body are equally liable to the affection.

HYDROCELE IN CONNECTION WITH IMPERFECT DESCENT OF THE TESTIS.—When the testis is arrested within the abdominal cavity no tunica vaginalis testis is developed, and therefore there can be no intra-abdominal hydrocele formed. But when the organ has passed beyond the bounds of the abdominal wall, then a processus vaginalis testis will always be found of a smaller or greater extent, and a hydrocele may therefore be in evidence. Further, it is true that when a testis is retained within the abdomen sometimes a processus vaginalis may be drawn down into the inguinal canal, the scrotum, or even into the perineum or Scarpa's triangle. It is possible, then, to have a hydrocele outside the abdominal wall with a testis which is completely retained within that cavity. A short classification of hydroceles in connection with imperfect descent of the testis may be given as follows:—Inguinal, scrotal, bilocular and trilocular, peritoneal and in Scarpa's triangle. An inguinal hydrocele may be further subdivided into two classes—one in which the testis is still within the abdomen and the other in which it is lying in the inguinal canal.

Inguinal hydrocele with the testis in the canal is the most common form of hydrocele in association with an arrested testis. When there is a communication of the processus vaginalis it may be either a very free one or it may be blocked by the testis. When the tunica vaginalis is shut off from the general cavity of the abdomen the hydrocele may be unilocular or multilocular. The fluid found within is of the ordinary serous hydrocele nature or is inflammatory in its origin and characters. In a certain number of instances the testis, when it occupies a position at the upper limit of the canal, acts as a plug to the deep abdominal ring and thus prevents the return of the fluid within the sac except under special conditions. Unilocular hydroceles with the communication with the abdominal cavity shut off may be acute or chronic, the acute being as a rule due to inflammatory attacks, while the chronic is probably caused by slight recurrent inflammations. The multilocular hydroceles are the outcome of inflammation, which has not only caused the formation of the fluid but has led to production of adhesions which have divided up the

cavity of the tunica vaginalis. Truss pressure is not a marked cause of hydrocele, for out of 936 cases in which a truss had been worn only thirty-two were complicated by a hydrocele. A scrotal hydrocele is one in which the processus vaginalis testis has passed into the scrotum beyond the place of the arrest of the accompanying testis. As a rule, that part of the pouch which lies below the superficial abdominal ring becomes shut off from the rest before the onset of the hydrocele. Such a condition is not so very uncommon.

A second variety of hydrocele occurs when the testis is arrested whether within the abdomen, in the inguinal canal, or just below the superficial ring, and that portion of the processus vaginalis which lies in the canal becomes distended with fluid and, being unable to contain more without further space, a secondary sac is formed in one of the planes of the abdominal wall. Sometimes this additional portion is protruded in the space between the aponeurosis of the external oblique and the muscular tissue of the internal oblique muscles.

The third variety is very rare and consists of a secondary sac lying in the extra-peritoneal tissue behind the body of the os pubis in the pelvis. The three varieties may be respectively termed the deep interstitial, the superficial interstitial, and the properitoneal. Sometimes the superadded sac may become of enormous size and may mount up on the abdominal wall so as to lie in such position as to simulate a hydronephrosis.

HERNIA IN ASSOCIATION WITH IMPERFECTLY DESCENDED TESTES.—It is probable that a hernial protrusion is the most frequent pathological condition associated with imperfect descent of the testis. The exact frequency in which inguinal hernia accompanies imperfect descent of the testis is difficult to estimate, but from a review of a large number of cases it is distinctly more than half. As has already been seen, in the majority of cases of arrested testes there is an associated want of formation or arrest of development of the adnexa. Thus it happens that there remains a patent process of the peritoneum into which abdominal viscera may descend. It is, however, necessary, as in the hernia of congenital type with a testis normally placed, that there should be some other besides this primary predisposing factor, and, indeed, other than the imperfect development which so often accompanies imperfect descent. Neither of these two factors is in itself sufficient actually to determine protrusion; 35 per cent. of the cases of hernia with arrested testis occur in the first year of life, while of those in persons who are not affected with imperfect descent, only 7.7 per cent. commence before twelve months of age, showing that the congenital defect has an undoubted influence on the onset of the protrusion. Inguinal and abdominal inclusion favour the early development of a hernia. The exciting causes may be such as are present in other so-called congenital hernia—viz., disease of the lungs, over-distension of the abdomen by intestinal gas, obstruction to the outflow of urine, constipation, and other less common conditions. It may be also true that the presence of the testis in the inguinal canal may in itself prevent the proper sphincter-like action of the lower fibres of the internal oblique and transversalis. This and other reasons would seem to show that the position in which the testis is arrested plays an important part in the frequency with which a hernia is developed.

There are at least five varieties of inguinal hernia associated with imperfect descent of the testis—namely, bubonocoele, scrotal, interstitial, cruro-scrotal, and superficial perineal. As would be naturally expected a bubonocoele is the most frequent form of inguinal hernia to be met with in association with imperfect descent of the testis. It is, moreover, the early stage of several of the other varieties. With the non-closure of processus vaginalis nothing is more likely to happen when the testis lying in the inguinal canal than that some of the abdominal viscera should prolapse into the waiting sac. A bubonocoele may also be associated with a testis which has transgressed the confines of the inguinal canal and is lying in front of the body of the os pubis. Further, a scrotal hernia may be associated with imperfect descent of the testis. By this term is meant a pro-

trusion which, having left the inguinal canal through the superficial ring, has passed into the scrotal tissue and has not distended the fold between the scrotum and the thigh.

By an interstitial hernia is understood an inguinal protrusion, a part or the whole of the sac of which is placed in one or other of the planes of the abdominal wall, transgressing the ordinary limits of an inguinal hernia. Interstitial hernia may be associated with imperfect or abnormal descent of the testis. On the other hand, they are also found present in males whose testes have reached their normal position in the scrotum. And, further, they actually occur in female subjects in a proportion greater than in the male sex; and, lastly, all instances of inguinal hernia associated with imperfect descent of the testis are not of the interstitial variety. These statements of fact go to prove conclusively that imperfect transition of the testis is not a necessary accompaniment of interstitial inguinal hernia. An examination, however, of a large number of cases of this form of protrusion in males leads to clear evidence that imperfect descent of the testis has a marked bearing upon a development of the hernia. Nearly 1 per cent. of inguinal hernia in male subjects are of the interstitial variety; 5 per cent. of those who show hernial protrusions with imperfect descent of the testis present one or other of the varieties of interstitial hernia. In males 73·4 per cent. of interstitial inguinal hernia are associated with more or less imperfect descent of the testis. The position of the arrested testis is a matter of great interest in view of the relationship which undoubtedly exists between the imperfect descent and the interstitial sac. In the majority of instances the arrested testis is found in the inguinal canal and at a position towards the lower end of that space. Next, it is most usually seen just below the superficial abdominal ring, and in some of these latter cases it is conceivable that it may have been pushed by the oncoming hernia through the superficial ring. In a few instances it may be found lying on the aponeurosis of the external oblique and towards the anterior superior spine of the ilium, again having reached the spot by the pressure exerted by the protruded viscera.

There are three chief varieties of interstitial hernia usually described. In the first the sac is found between the aponeurosis of the external oblique and the muscular fibres of the internal oblique, and this is the one which is most frequently associated with arrest of the testis. It usually presents an external swelling which is very characteristic in its shape and extent; beginning in the region of the inguinal canal, it mounts upwards and outwards towards the anterior superior spine of the ilium. The whole course of the gradual formation of the tumour can be observed if a patient, after the contents of the sac have been reduced, is directed to lie on his back and cough. There is no other condition that will give the spectacle of a gradually increasing tumour under these circumstances. The shape of the swelling is usually ovoid, and its margins are fairly distinct. It is flattened on the surface and does not project far from the abdominal wall. When there is a scrotal portion as well as an interstitial, the former is usually secondary to the development of the latter and usually indicates that the resistance to the increase in the primary part has become greater than that to the entry of the viscera into the scrotum. The second variety of interstitial hernia is that in which the sac is placed between the aponeurosis of the external oblique and the skin. It also is not infrequently associated with an arrest of the testis. The method in which the sac has arrived at its position may be one of two. Either the peritoneum has been pushed forward and then upward through a gap in the aponeurosis, or the sac, at first lying in the inguinal canal, has transgressed the bounds of this space, protruded through the superficial ring, and finding its way into the scrotum blocked has turned upward on the abdominal wall. In both of these the direction taken by the hernia is that of the least resistance, for the attachment of the deep layer of the superficial fascia to the front of Poupart's ligament would bar its progress into the thigh. As a

rule, the external swelling present in the second variety is more pronounced than that of the first. The third form of interstitial hernia is that in which the sac lies in the plane between the transversalis fascia and the peritoneum, that is, in the extra-peritoneal tissue. This is a rare form and one which is not so commonly associated with imperfect descent of the testis.

By a cruro-scrotal hernia is meant a hernial sac which distends not the scrotal tissues but the fold of skin which is found between the scrotum and the thigh. The hernia, therefore, will be covered with ordinary cutaneous tissue and not with dartos. It is always associated with an imperfect or abnormal descent of the testis, and the hernia follows the organ. The testis, usually an imperfectly developed one, having left the inguinal canal, is for some reason—probably a want of development of the scrotal tissue or a tenseness of the fascia at the entrance of the scrotum—prevented from continuing its further descent into that region. It will therefore remain permanently in the cruro-scrotal fold, or pass into the perineum or possibly into Scarpa's triangle. If the processus vaginalis testis which accompanies it remains patent viscera may descend into it and gradually distend the fold so as to form a cruro-scrotal hernia. As the hernia progresses the pouch becomes larger and more definite, and hangs directly downwards and does not pass backwards into the perineum. On examining a patient who is the subject of this form of hernia it will be first noticed that the scrotum is either imperfectly developed on one side or, being developed, it is not distended. Lying external to it and separated from it by a distinct sulcus, is an adventitious sac covered with normal skin. On the patient being requested to cough, an expansile impulse will be felt in the swelling. The contents of the sac are usually reducible, and after reduction a small testis may usually be felt fixed at the bottom of the pouch of skin which, when the viscera are not distending it, hangs lax and is thrown into folds.

A hernia which accompanies the testis into the tissues of the perineum may be designated a superficial perineal hernia, it being termed superficial to distinguish it from that rare form of perineal hernia which leaves the pelvis through a gap in its floor. The course of the descent of a superficial perineal hernia is from the abdomen, along the canal, through the superficial ring, past the scrotum near its entrance, and then backwards towards the margin of the anus. This form of hernia is necessarily rare, for perineal ectopia of the testis is uncommon, and even when present an accompanying hernia is seldom seen. It appears as an elastic swelling on one side of the perineum with an expansile impulse on cough, frequently resonant on percussion, and usually reducible on pressure. After the return of the contents of the sac, the testis, sometimes well developed, can be felt lying by the side of the anus, and often tethered by a band, probably of the gubernaculum to the region of the external sphincter or tuberosity of the ischium.

Clinical Records.

JERVIS STREET HOSPITAL.

Case of Pseudo-Elephantiasis. (a)

Under the Care of Wm. J. THOMPSON, M.D., M.R.C.P.,

Physician to Jervis Street Hospital, Consulting Physician to the National Hospital for Consumption, Ireland.

THE patient was admitted to Jervis Street Hospital a couple of days ago complaining of acute pain in her left side. On examining the part the spleen was found to be enormously enlarged, extending downwards almost to the crest of the ilium, and inwards as far as the umbilicus. Further examination revealed the interesting condition of the left leg, which she had never before shown to anyone or spoken of in any way. It might, I think, be classed as a case of pseudo-elephantiasis. She is sixty-two years of age; her family history is good, both her parents lived to advanced ages, neither of them had ever been abroad, and she was never out of this coun-

(a) Paper read before the Royal Academy of Medicine in Ireland, Section of Medicine, March 7th, 1902.

try. She has always been strong and healthy, and has been a domestic servant for forty years. About thirty years ago she first noticed a swelling in the upper and outer part of the leg, about the region of the great trochanter which came on very slowly, gradually extended inwards (surrounding the leg) and downwards. This swelling at first was always moist on the surface, so much so that it kept her underclothing damp, but, as far as the patient remembers, never stiffened the linen. In about seven years the whole leg down to the ankle was involved. At the time of her change of life, twenty-three years ago, she had some very severe attacks of uterine hæmorrhage, which necessitated her resting in bed, and she affirms while so resting the swelling in the upper part of the leg commenced to get smaller. She was never married, and never had any trouble at her menstrual periods. The leg at present is about the same for the past fifteen years, except that the exudations have stopped and the surface has lately become very dark in color and quite rough. As you see there is great thickening and enlargement between the knee and ankle-joint. The measurement at the thickest point is 26 ins., at the same point on the right leg it only measures 11½ ins. Since her admission into hospital the swelling has become much softer and less resisting—probably due to the rest in bed. The foot and as far on the ankle as the shoe fitted is scarcely swollen and the swelling above this hangs quite over the foot when the patient stands up. From the thigh to the knee the swelling is not nearly so marked; thickest part measures 24 ins. and the measurement at the corresponding point on the opposite leg is 15 ins. Up to her admission she was at work as cook, and except for the feeling of heaviness, never had any pain. She is positive that at no time had she any attack of pain or burning feeling in the swelling as is so often described in such cases. The average quantity of urine passed per diem is 42 ozs. It is acid in reaction, sp. gr. 1017, no trace of albumin, sugar, or chyle. She is pale, thin, and emaciated, and states that for the past year she has lost flesh rapidly. As far as I can make out it is not usual to have the spleen enlarged in such cases, and it is an interesting point whether in her case the splenic trouble is a distinct and separate disease, or whether both belong to the same category. Elephantiasis is essentially a disease of tropical countries, and in cases found in these parts the *filaria sanguinis hominis* is found in great numbers. Climate and locality, combined with bad living, are doubtless the predisposing cause. No race is exempt from it, but the white suffer less than the dark. It affects both sexes, more especially the male sex; it occurs at all ages, and it is found in all conditions of life, but is more usual in adult and middle life. It is doubtful if hereditary taint has any marked predisposing effect. It is a chronic disease, as, according to Richards, the average duration from observations made on over 600 cases is eleven and a-half years. Keen and White, in their "Surgical Text Book," describe a case under observation for seventeen years, and during that time the patient had repeated attacks of lymphangitis, each of which produced an aggravation of the previous condition. Dr. Archer, of the Barbadoes Hospital, described a case in the *British Medical Journal* of 1900, occurring in a black, æt. 40, and of five years' duration. The circumference of the leg was 45 ins. Amputation was performed and the patient made a good recovery.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MARCH 14TH, 1902.

Mr. HOWARD MARSH, F.R.C.S., President, in the Chair.

TWO CASES OF ARTHRITIS OF THE KNEE.

MR. PAGE briefly recorded the clinical history of two cases of arthritis characterised by considerable effusions into the joints, which did not subside under the influence of rest, warmth and local remedies. Their etiology was obscure. In both instances they had been attri-

buted to a slight injury, but the severity and stubborn character of the arthritis made it unlikely that such was the complete explanation. When these joints were aspirated a greenish, cloudy fluid was obtained, floating in which were flakes of lymph and leucocytes. Aspiration of the joints was followed by a re-accumulation of the fluid and return of pain, and it was observed that when the arthritis was at its height the patients were slightly delirious. In both cases recovery had rapidly followed aspiration together with irrigation of the joints with a one per cent. solution of carbolic acid. In the second case full doses of salicylate of soda given after the joint had been treated by aspiration and flushing with carbolic, appeared materially to promote recovery. Mr. Page was of opinion that this form of arthritis which in its clinical course was unusual, must be the result of an infection of the joint by a micro-organism which had a special affinity for the tissues of the joints, and he drew attention to them now, because Dr. Poynton and Dr. Paine had demonstrated, isolated and cultivated such a micro-organism, and had produced experimental results which led to the conclusion that this organism was the exciting cause of the arthritis.

Dr. POYNTON and Dr. PAINE described the investigation they had made in the second of the two cases described by Mr. Page. Upon two occasions they had found in the exudation numerous small diplococci growing in chain. The exudation contained in addition fibrin, and leucocytes which were not necrotic. This diplococcus grew well in pure culture, in an acid medium of milk and bouillon, in bouillon to which had been added ascitic fluid, and on blood agar. The cultural and morphological characteristics were indistinguishable from those of the diplococcus of rheumatic fever. Intravenous inoculation into rabbits produced a condition more akin to that which results from inoculation with the diplococcus of rheumatic fever than that which results from the streptococcus pyogenes. That is to say, multiple arthritis, and in one case valvulitis resulted, without visceral suppurations. The spleen after death was small, and in none of the four experiments that were made did death result from septicæmia. On the contrary, two of the animals recovered completely, after showing local signs of infection, and two were killed when the arthritis in each case had existed for two months. Quite independently from Mr. Page they had by bacteriological investigation arrived at the conclusion that the infection was an unusual one; and this investigation pointed to the probability that the condition was more closely allied to a rheumatic than to a suppurative arthritis. The scientific interest of the question lay in the light that such an investigation might in the future throw on the etiology of rheumatoid arthritis, and the vexed problem of rheumatic and septic processes. One other point was worthy of note, viz., that many diplococci were present in the exudation. Dr. Poynton and Dr. Paine had found that the acute and clear effusions of rheumatic fever were usually sterile both in man and in animals, but nevertheless the diplococcus might be found in the synovial membrane. They thought that the endothelial lining of the synovial membrane was an important barrier to their escape, and that in this case of arthritis this barrier had been in all probability much damaged.

MALIGNANT ENDOCARDITIS GIVING WIDAL'S REACTION.

Dr. HALE WHITE and Mr. PAKES gave an account of a patient who was in the hospital for malignant endocarditis from which she died owing to cerebral embolism. The blood on June 10th failed to agglutinate typhoid bacilli even in a strength of 1 in 2. On June 10th agglutination was produced with a strength of 1 in 2 and 1 in 20, but not with a strength of 1 in 200. Pure cultures of streptococcus longus were obtained from the blood. On June 29th cultures from the urine collected with every precaution showed the presence of a streptococcus identical with that previously obtained from the blood, and a bacillus belonging to the paracolon group. Every attempt to isolate the typhoid bacillus failed.

The agglutination test was tried with five different strains of bacilli and with four a complete agglutination was obtained with a dilution of 1 in 20, and with one a partial agglutination was obtained with a dilution of 1 in 200. On September 13th the patient died. Blood taken from the heart and the spleen showed streptococcus longus in pure culture, but no typhoid bacilli could be discovered. The patient never had spots or other signs of typhoid fever, nor were any signs of healed ulcers found post-mortem. Thus, this is an instance of a patient who, suffering from malignant endocarditis of streptococcal origin without any clinical, post-mortem, or bacteriological evidence of typhoid fever, yet nevertheless developed in her blood serum certain substances which had the power of agglutinating the typhoid bacillus. The authors point out the clinical importance of this result in considering the diagnosis between typhoid fever and malignant endocarditis, and also the fact that many observers have failed to obtain a Widal reaction in malignant endocarditis. In this peculiar case the presence of the reaction cannot have been due to the patient having had typhoid previously, for no reaction was obtained when she was admitted. She was treated with various strains of anti-streptococcal serum, but without any good result.

In the discussion which ensued the general opinion appeared to be that, although Widal's reaction is not an infallible guide to diagnosis, it furnishes invaluable aid, especially if the technique be rigidly adhered to and a suitable dilution employed.

Mr. SNAES read a paper on a case of

ACUTE PARALYTIC DILATATION OF THE STOMACH, which occurred in a medical man, *æt.* 30. The disease commenced insidiously with an intermittent fever of obscure origin, and was accompanied with constipation, fecal accumulation, and progressive loss of flesh. Previous to the dilatation of the stomach, phlebitis of the veins of the left leg and iliac region occurred, and later the stomach became suddenly distended, and on passing an oesophageal tube three quarts of a dark green sour-smelling fluid were withdrawn. Vomiting was never present, and no peristaltic waves were observed. Complete recovery followed daily lavage of the stomach, and up to the present time, just twelve months, no recurrence of the disease had taken place.

Dr. LEE DICKINSON and Dr. W. J. FENTON gave the completed history of a case of Lymphadenoma with Growths in the Skin. The living patient, a boy, *æt.* 16, had been shown at the Society last April, the main interest attaching to the growths in the skin, as to the true nature of which some difference of opinion was expressed. Anti-syphilitic treatment was adopted without benefit, and the disease progressed steadily in the glands and internal organs, and ended fatally in August. The post-mortem appearances were those of the hard form of lymphadenoma in glands and spleen, and secondary growths of the same character were found not only in the skin, but in the dura mater, and in the cancellous tissue of the tibia. The liver was lardaceous, and contained an unmistakable tuberculous focus, but elsewhere no tubercle was found. The case, therefore, proved to be one of lymphadenoma upon which tubercle had supervened.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING AT THE ROYAL COLLEGE OF PHYSICIANS, ON FRIDAY, MARCH 7TH, 1902.

The President, SIR CHRISTOPHER NIXON, in the Chair.

Dr. WILLIAM J. THOMPSON introduced a case of PSEUDO-ELEPHANTIASIS

in a patient admitted to Jervis Street Hospital a few days ago, a description of which will be found in another column under the heading of "Clinical Records." In discussing the case,

Prof. McWHEENY remarked that save for a moderate polymorpho-nuclear leucocytosis and an increase in large hyaline leucocytes of transitional type, the blood

exhibited no abnormality. He had observed three cases of this kind. In one, lymphorrhœa was a prominent feature, and the patient, a young man, ultimately died of septic intoxication. The two others were middle-aged men, and were treated by amputation. In both cases he had satisfied himself by dissection that the cause of the lymphatic obstruction was chronic tuberculous lymphangitis. The histological features were interesting, and comprised immense thickening of the epidermis, especially of the *strata lucidum* and *corneum*, thickening of the true skin with dilatation of the lymph spaces, and general œdema. All fibrous structures showed marked overgrowth. The lymphatics were accompanied by streaks of small old infiltration, in which multinuclear giant cells of tuberculous character were embedded. The skin was about ten or twelve times as thick as normal. In both of these cases he had convinced himself that the pseudo-elephantoid condition was of tuberculous origin, and had confirmed his view by discovering the bacilli in one of them.

Sir GEORGE DUFFY stated that not long since he met with a similar case of pseudo-elephantiasis of both legs, in a patient who had formerly suffered from eczema, he ascribed it to chronic lymphangitis excited by eczema. The blood showed nothing abnormal, it was carefully examined for filaria, but none were found.

Mr. TOBIN some years ago met with a case of the disease. The importunity of the patient induced him to tie the femoral artery of the side affected, but the operation, which he performed contrary to his own opinion, did no good.

Dr. WM. J. THOMPSON, in reply, said that there was no history of eczema.

Dr. J. MAGNE FINNY and Dr. ED. J. M. WATSON on

CASES ILLUSTRATING THE AID OF X-RAYS IN THE DIAGNOSIS OF INTRATHORACIC TUMOURS.

Dr. Finny called attention to the difficulties which attend the diagnosis of an intrathoracic tumour by the ordinary methods of clinical tests, not only as to its actual presence, but also as to its nature, and he claimed for the X-rays a position and a most valuable aid in clearing up the doubts which must attend such cases as regards (a) the presence of a new growth or an aneurysm, (b) the pulsatile or non-pulsatile nature of the tumour, (c) the exact position and dimensions of the tumour. Dr. Finny submitted skiagraphs which Dr. Watson had taken of three cases which occurred in 1901, and detailed the clinical records.

Case I. was an example of sarcoma of the right lung which occurred in a woman, *æt.* 30, and whose illness commenced by hæmoptysis. When admitted, under Dr. Finny's care, in Sir Patrick Dun's Hospital in February, 1901, the right side of the thorax was apparently full of fluid and was opaque to the X-rays, so that no information was at that time afforded. The suspicion that something more serious than pleural effusion was aroused by the fact that the right mamma and the subcutaneous tissue of the right side were thick and cedematous and the veins varicose with a downward blood stream. After 72 ozs. of serum, clear and free from inflammatory or other morbid products had been with drawn, Dr. Watson took the skiagram (exhibited), and it was then evident that a tumour existed in front of and to the right of the vertebral column, occupying more than three-fourths of the lung space below the level of the fourth rib and extending to within a short distance above the diaphragm. Although the tapping gave relief to the dyspnoea and some of the other symptoms, the solid œdema, the varicosity of the veins, and the other evidences of intrathoracic pressure did not disappear, but rather increased, causing cyanosis and dysphagia, and the patient died at home four and a-half months subsequently in an attack of breathlessness. No post-mortem was possible. The disease was primary, and considering the age of the patient it was presumably sarcomatous, and had its origin in the connective tissue of the glands in the posterior mediastinum, and grew peripherally, invading the lung and pleura.

Cases II. and III. were examples of aneurysm of the aorta occurring in adult males, *æt.* 42 and 54 respectively; the first of the arch, the latter of the descending

thoracic aorta. In Case II. the aneurysm had probably existed for two or more years, the evidences of an aneurysm of the ascending and transverse portions of the arch were readily made out, both the X-rays showed that the whole arch was involved, and that the sac was much larger than physical examination could determine, and extended quite as much to the left as to the right of the middle line. The sac bulged forward behind the sterno-clavicular joint and above the sternum, pushing the trachea to the left side. Tracheal tugging was manifest, and the pulse was absent from the left brachial and radial arteries. In Case III., on the other hand, the patient had been quite free from all history of aneurysm till two months before being seen, and there were no physical signs of any sort, the only symptom being one of pain referable to the third intercostal space in the left mammary line and extending to the left shoulder. This pain was at times so severe as to necessitate cessation of all work, the patient having to sit down or stand still in the midst of his labour or while walking in the street, and yet the X-rays showed a very distinct shadow in the region of the aorta, above the heart, extending well to the left side, and, more than that, the tumour was seen by the screen to be distinctly pulsatile, enlarging with each systole of the heart. In both cases a modified Tufnell treatment was adopted, and iod. potass. administered for five to seven weeks, and both patients left hospital greatly benefited as regards pain. Recent information is to hand that Case II. is still well, ten months after treatment, and has been quite free from any symptom (while in hospital he was on the point of death by asphyxia for three days, owing to the presence of the aneurysm in the trachea and bronchus), and Case III. has been at work for over two months without intermission. Dr. Finny looked upon the improvement recorded as rather a coincidence than as the result of treatment, which was carried on imperfectly and for quite too short a space of time, and is but an example of the variability of the growth of an aneurysmal sac, and the temporary improvement which may follow a change of direction of the yielding wall. At the same time this very peculiarity, as was first pointed out by Stokes ("Dis. of Heart and Aorta"), gives the keynote of diagnosis between an aneurysm and a malignant growth.

An interesting paper was then read on

THE USE OF X-RAYS IN MEDICAL DIAGNOSES

by Dr. HAUGHTON, who said that during the past six years the X-ray examination of a large number of patients (some 1,900 odd) in hospital and private practice had convinced him that while surgery and dentistry made increasing use of X-rays, medicine in this country had not fully availed itself of their aid. The reason might be twofold—a natural diffidence to adopt a new and untried method, or neglect on the part of advocates of the process to call attention to its value in medicine. The difficulty was now removed by the records of splendid work from Continental centres; and with regard to the second he might state that some three years ago he had the honour to call attention to this matter before the Pathological Section of the Academy, and in a Presidential Address before the Dublin University Biological Association. In pulmonary tuberculosis the great value to patient and physician of an early diagnosis was referred to, and in his opinion X-ray examination in chest cases would come into very general use when the true value was justly estimated. Before describing his method of examination Dr. Haughton stated that in his opinion the fluorescent screen was preferable to photography, because cardiac movements disturbed the lung a good deal, and though respiratory movements could be avoided by very short exposures, the heart movements always spoiled the photographic result. We are having a number of illustrations engraved for this paper, which we hope to publish in full next week.

Dr. KIRKPATRICK considered the paper just read by Dr. Haughton as one of exceeding great value as a supplemental aid to the ordinary methods of diagnosis. But the X-rays do more than this, for they give information unobtainable by any other method. He was particularly struck with their value in pneumonia. Acute croupous pneumonia is said to get quite well, and

the physician looks on the case as cured; but by the aid of the X-rays in one of his cases, Dr. Haughton had demonstrated to him that the lung had not recovered its elasticity, and acting on the information he secured the patient sick leave and rest until the X-rays demonstrated that the lung had returned to the normal. In a case of broncho-pneumonia, Dr. Haughton demonstrated to him that the diaphragmatic excursion was limited to less than normal on both sides. Its value in the incipient stage of phthisis was made clear in a case of his in which the patient had had a vomiting of blood. The loss of blood did not recur, and when examined no physical sign of disease was discernible; by the X-ray screen Dr. Haughton showed an opacity in the apex of the left lung and a diminished excursion of the diaphragm on the affected side. Since then the patient has developed the ordinary physical signs of tuberculosis, and bacilli are found in her sputum.

Dr. LANE JOYNT considered that they were greatly indebted to Dr. Haughton for his excellent paper and his demonstrations of the rise and fall of the diaphragm, the value of which information can hardly be over-estimated in dealing with thoracic diseases. He recommended all physicians to bear well in mind that all skiagraphs exaggerate the size of the part photographed, and this amount of exaggeration is dependent on the distance of the object from the plate; thus a distance of four inches from the plate gives an enlargement of one-fourth.

The PRESIDENT also spoke.

Dr. FINNY thanked the members present for the kind reception accorded to his cases, and referred to the great interest and pleasure Dr. Haughton's paper had given him.

Dr. HAUGHTON, in thanking the members for the way they received his paper, desired to say that Dr. Watson's skiagraphs of the thorax as shown by Dr. Finny were the best he had seen. The thorax was difficult to photograph with the X-rays, and he thought it was due to Dr. Watson that the excellence of his skiagraph should be acknowledged. With Dr. Lane Joynt he recognises that all X-ray photographs exaggerate the size of the object, due to a disturbance of the visual angle. He, however, hopes to correct this error by triangulation.

The meeting then terminated.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, MARCH 6TH, 1902.

Mr. WATSON CHEYNE, F.R.C.S., President, in the Chair.

Dr. LONGRIDGE showed a girl, *æt.* 7, with an irregular temperature of three months' duration, for which no obvious cause could be found. Typhoid had been eliminated by repeated non-reaction to the Widal-Grünbaum test. No evidence of tubercle could be detected. The tuberculin test was disallowed on account of the irregularity of the temperature. The only evidence of disease that could be detected were König's sign, which had lasted for six weeks, a transient erythematous rash, some pain and swelling of the wrists, the temperature and wasting. The child was not anæmic. There was some leucocytosis, and she took her food very well.

Dr. PENROSE considered the case to be an obscure rheumatic condition.

Dr. CAUTLEY thought it might be an early case of osteo-arthritis, and he believed there was a little swelling about the wrist-joint. If so that would support the view, and febrile attacks were a feature of some such cases. He had never seen a case of such long duration without definite joint change.

Dr. LONGRIDGE, in reply, said he had seen cases of osteo-arthritis in which the causal factor seemed to be a septic condition of the teeth, but the condition cleared up when the teeth were purified. The present child had bad teeth, but they were not septic. The family history was good. She had two brothers older than herself, and a younger sister, all robust. The only diseases the present child had had were whooping-cough and measles.

Dr. E. CAUTLEY showed a case of

DISEASE OF THE CAUDA EQUINA.

The patient, *et.* 26, had a chancre eight years ago, and presented a scar on his penis. He was quite well until last October, when he had sudden retention of urine. Four days later he could not hold his motions. He was treated by catheterisation and aperients, both as an out-patient and an in-patient, at a hospital, but the disease was not diagnosed. Later on, the actual cautery was freely applied to the sacral region when he was in the infirmary. In December he began to have some loss of power in the left leg and numbness in the buttocks. At present he exhibits some loss of power in the extensors of the left leg. The cremasteric and patellar reflexes are very active, while the plantar reflex is lost. The sphincter ani has lost power and does not grasp the finger on examination. There is diminution of sensation to touch, pain and temperature, with a feeling of numbness over a considerable area of the buttocks, the perineum, penis and scrotum. Testicular sensation is impaired. He could not pass water at first, but now has partially regained control over the bladder. Stools are occasionally passed unconsciously. The probable diagnosis was syphilitic disease of the cauda equina, that part from which the second, third and fourth sacral nerves arise. He was treated with mercury and potassium iodide.

Dr. CAUTLEY also showed a typical instance, clinically, of Primary Lateral Sclerosis in a man, *et.* 25. No possible exciting cause had been found, except gonorrhoea, about two years before the onset, which took place three years ago.

The cases were also discussed by Dr. Sutherland, Dr. Longridge, and Mr. Jaffrey.

Mr. P. L. DANIEL read a paper on "Some Rare Cases of Sarcoma of the Thyroid Gland," and exhibited a large number of pathological and microscopical specimens from cases which had suffered from this disease.

The President said sarcoma of the thyroid was apparently not very common. He was interested in the statement that out of six cases of malignant disease of the thyroid at Charing Cross Hospital, four were sarcomata. He had not generally examined such cases histologically, but had accepted the statement of the books as correct that sarcoma was much more rare than carcinoma. He had not yet encountered a case of malignant disease of the thyroid which he felt justified in operating upon; and those cases which did not seem to benefit under treatment were not kept in hospital, so that no opportunity of post-mortem examination was afforded. The most interesting question was that of treatment, because malignant disease of the thyroid was one of the most terrible forms, on account of the great distress it caused. In one case which was diagnosed as sarcoma of the thyroid, a good deal of benefit resulted from the use of Coley's fluid. One case went on for more than a year; it was injected with Coley's fluid, and apparently there was a complete cessation of the growth. But she had influenza and it lighted up again.

Mr. CAMPBELL WILLIAMS asked whether there was any pigmentation in the skin in these cases? He agreed that primary sarcoma or epithelioma of the thyroid was rare.

Dr. CAUTLEY asked whether in any of the cases the growths in the thyroid were secondary. Occasionally in cretins who were improving under thyroid treatment, if the treatment was stopped the thyroid began to enlarge, but it would go down again on the resumption of the treatment. There was, no doubt, a connection between the thyroid gland and the sexual functions.

Dr. LONGRIDGE asked whether there were any secondary growths in the bones, and if so, whether such growths partook of the histological character of the thyroid itself?

Mr. DANIEL, in reply, said the skin was not pigmented. He showed a specimen in which there were secondary nodules affecting both lobules of the thyroid. With the exception of the spine in one case there had been no tumour of bone or lung in any of the cases, although the walls of the subclavian vein were undoubtedly involved. On section the new growths in the spine were seen to be simply pure sarcomata.

LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MARCH 7TH, 1902.

The President, Mr. E. CRESSWELL BABER, F.R.C.S., in the Chair.

Dr. FITZGERALD POWELL showed a case of complete "Recurrent Laryngeal Paralysis" in a man, *et.* 24. The patient stated that in March, 1901, he suddenly lost his voice, which returned after three months' treatment. In December he again suddenly lost his voice and came under Dr. Powell's care. On examination complete paralysis of the left vocal cord was found. There was an entire absence of any of the usual causes which produce such a paralysis. The patient stated that at the time of the first attack his doctor considered he had influenza. At the present time there was some movement in the cord, and the voice had suddenly undergone great improvement. Sir FELIX SEMON considered that the paralysis was originally due to influenza, and that some extra vocal effort or a cold would be sufficient to produce a recurrence.

Dr. POWELL also showed a case of "Hæmatoma of the Vocal Cord" in a female, *et.* 29, the symptoms of which were hoarseness and loss of voice coming on suddenly, and there was sluggish movement of the left cord. Dr. F. de Havilland Hall pointed out that the hæmorrhages often coincided with the menstrual period or some catamenial disturbance.

Dr. POWELL exhibited a modification of Mackenzie's laryngeal forceps for the removal of growths in the anterior commissure and also drills for draining the maxillary antrum through the tooth socket.

Dr. F. WILCOCKS showed a case of "Paralysis of the Left Vocal Cord," symptoms of which had been present since last Christmas. There was no history of syphilis and no signs of any intra-thoracic pressure. Dr. de Havilland Hall thought that although there were no physical signs paralysis was probably due to the pressure of an aneurysm. Mr. P. de Santi, Sir Felix Semon, and Dr. J. Donelan instanced cases in which the paralysis of the left cord had preceded any other signs of an aneurysm.

Mr. H. BETHAM ROBINSON showed a case of

LARYNGEAL STENOSIS

due to cicatricial contraction in the inter-arytænoid region in a young man, *et.* 20, who complained of difficulty of breathing on exertion. He gave a history of diphtheria some years previously, which had left him with an impaired voice. The voice had gradually improved, so that now it was only husky. Examination showed a perforation of the nasal septum, loss of the uvula, and a cicatricial web passing between the aryttænoids. There was no history of syphilis. Sir Felix Semon pointed out the importance of carefully distinguishing between true paralysis and loss of abduction due to mechanical causes as seen in this case. The opinion of members of the Society was divided as to whether the cicatricial web was due to diphtheria or syphilis.

Dr. A. BRONNER showed sections of a tuberculous growth of the mucous membrane of the right middle turbinate in a man, *et.* 50. Dr. St. Clair Thomson mentioned that tuberculosis of the middle turbinate was extremely rare.

Mr. DE SANTI showed a case of "Tertiary Intra-nasal Syphilis," in which the right frontal sinus had been opened twice with negative results in a man, *et.* 43. He invited suggestions as to further treatment. Several members considered that there was probably a sequestrum at the junction of the sphenoid and the vomer, and advised that this region should be explored.

Mr. DE SANTI also showed a case of "Angio-neurotic Edema" of the right hand accompanied by attacks of dyspnoea in a woman, *et.* 26. Though examination of the larynx revealed no oedema or abnormal condition, he pointed out that cases had been recorded in which death from suffocation had occurred due to sudden oedema of the larynx.

Dr. H. LAMBERT LACK showed a case of "Rapidly Recurring Papilloma of the Larynx." When first seen

the patient had a growth on the right vocal cord, which was removed. This was followed by considerable congestion and thickening of both vocal cords, which had gradually cleared up. At the present time there was recurrence of the papilloma on the right cord, and also two distinct growths on the other cord.

Dr. J. DUNDAS GRANT showed a case of "Traumatic Tracheal Stenosis" in a girl, *æt.* 22, dating from an accident at the age of three years. During the last six months she had been troubled by some dyspnoea.

Dr. G. C. CATHCART showed a case of "Rhinorrhœa" in a girl, *æt.* 9, which had existed since the age of two years. Adenoids had been removed and various intranasal operations performed, and both locally and internally a great variety of drugs had been tried without result. Dr. de Havilland Hall recommended a mustard footbath and the administration of atropine and morphia at the commencement of an attack. The treatment of such cases was further discussed.

Mr. R. LAKE showed a case of "Atrophic Rhinitis," in which melted paraffin had been injected into the inferior turbinated body with good results. The patient had been under treatment for many years, and was so far improved that crust formation had ceased, but she complained that she could not blow her nose. Mr. Lake had therefore endeavoured to contract the passages by enlarging the inferior turbinate by means of submucous injections of paraffin. These had proved most successful as far as the patient's comfort was concerned.

Dr. H. TILLEY showed a case of papillomatous growth on the posterior edge of the vomer. The growth was dead white in colour, contrasting very strongly with the normal redness of the surrounding structures. He regarded it as a harmless curiosity.

Dr. TILLEY also showed a case of Syphilitic Disease of the Larynx Simulating Malignant Disease. The right vocal cord was motionless on phonation, and there was considerable uniform swelling of its posterior half. There was also some ulceration below the cords.

PARIS, March 16th, 1902.

CYSTORECTOSTOMY.

ECTOPIA vesicæ has for centuries exercised the ingenuity and skill of surgeons. De Chauliac and Albucasis in the middle ages, and Wiseman in modern times, were not more puzzled over the lesion than the surgeons of the nineteenth century, whose unsuccessful efforts to remedy the ectopia are known to all senior medical students. We need not enumerate the operations that have been devised since Antoine Dubois and Baron Dupuytren declared that the lesion was not beyond the resources of their art, and hopefully strove to produce a radical cure. For fifty years British and foreign surgeons sought success on the lines laid down by Dupuytren. At best the results were poor, the victim of the malformation was forced to carry about his prosthesis, which in time gave forth an intolerable stench and excluded the patient from the society of his fellows. It is to the credit of British surgery that the first great advance made was effected in 1851 by Mr. Simon, who inserted the ureters into the rectum. The operation as performed had its drawbacks, but, as Maydl demonstrated at the International Congress in Rome (1894), the evils were those of technique, not of the principle of the procedure. He tried to remedy this by dissecting off the vesical mucous membrane surrounding the urethral orifice, and then transplanting the fold of membrane with its intact urethral orifices into the rectum. The results were better, the orifices remained patulous, but nephritis and rectal troubles followed. A recto-vesical

fistula gave no better results. But it did much for the art of surgery; it gave the idea of cystorectostomy to M. Soubotine, of St. Petersburg, to whom we are indebted for the most promising operations for the relief of the dangers and discomfort of *ectopia vesicæ*. M. Soubotine has now successfully performed the operation some six times, and the results exceed anything ever before obtained by surgical methods in this malformation. He publishes an account of the operation in the Bulletin of the Academy of Medicine of St. Petersburg in 1900, and last year published a paper on the subject in Moscow.

The operation is completed in three stages. He commences by placing the patient in the prone position, then by a long incision over the sacral spine down to the extremity of the coccyx he separates the latter from its attachment and removes it, laying bare the rectum, which he now longitudinally incises, exposing the anterior wall of the bowel, and preserving intact the anal sphincter. The second step of the operation consists in making an incision three centimetres long in the anterior wall of the rectum immediately above the sphincter. This incision lays bare the posterior wall of the urinary bladder, which is drawn down and back through the cut in the anterior wall of the rectum; its convexity is then cut, and the free edges of the rectal and vesical incisions are sutured together, thus forming a free communication between the bowel and the bladder; this completes the second stage. He now makes a horse-shoe shaped incision in the anterior wall of the rectum, the incision is prolonged to the cutaneous surface of the perineum; he thus obtains two flaps, each equal in size to one-third of the circumference of the rectum. The surface of the flap is lightly dissected up and their inferior borders sutured together in two sets of sutures, one passing from mucous membrane to mucous membrane and the other set uniting the muscular tissue. The incision in the posterior wall of the rectum is then closed, and finally the cutaneous wound; in two cases he covered the hiatus on the anterior abdominal surface by utilising the scrotal cutaneous tissue.

Four days after operation he introduces a sound into the urinary bladder through the newly-formed urethra. Strangely enough, the free opening between the bladder and rectum appears to close up quickly, and neither by washing the bladder nor by defecation is any evidence of the opening obtainable after a few days. The urinary cavity which forms at the expense of the rectum is found to easily contain 100 grammes of liquid, which the patient can retain for hours and eject with considerable force when necessary.

Such is M. Soubotine's operation. It differs from all others in that it provides a urinary bladder lined with its natural tissue, mucous membrane, and with muscular walls which act readily under the stimulus of the will. Thus within the century has been fulfilled the dream of Dubois and Dupuytren, and the untiring energy and ever watchful care of medicine been rewarded with success.

FIBRO-SARCOMA OF THE CORD.

This very unusual lesion is reported by M. Pantolini (*Arch. prov. de Ch.*). There was no difficulty experienced in its removal. A microscopic section of the tumour showed the well-known characters of a fibro-sarcoma. The case may be considered as almost unique. Fibrous

tumours of the cord have been removed by M. Lenoir, M. Letievani, and sarcomatous ones by Dr. G. Mason, of Philadelphia, A. M. Moullin, of London, and W. J. Walsham. There is no record as far as we know of a fibrosarcoma of the spermatic cord; indeed it is wonderful how free from neoplasms the structure is.

UNUSUAL CASE OF GLOSSO-LABIO-LARYNGEAL PARALYSIS.

At a recent meeting of the Société Médicale des Hôpitaux, MM. Variot and Roy exhibited a child nine years and a half old, who presented all the symptoms of glosso-labio-laryngeal paralysis. They consider that the condition was congenital. There is, however, no history given of this extremely interesting case, without which no idea of its being congenital or otherwise can be formed. Congenital cases of the disease are almost unknown, Hitzig, however, reports such a case (*Bull. Klin. W.*), the patient being at the time of writing six years old. Erh considers that Hitzig's case belongs to another class of disease. The disease is seldom met with before forty years of age. The cases of Kayser, of a boy, æt. 12; of Frerich's in a boy, æt. 10, and even Wachsmuth's case of a girl, æt. 17, are looked on as of doubtful diagnosis. It is interesting to note that the first description of the disease and the first attempt to explain its pathology was given in a letter to Sir Charles Bell by Dr. R. W. Robinson.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 15th, 1902.

At the Free Society of Surgeons, Hr. Goldstein read a communication on

INJURY TO THE KIDNEY.

He had collected twenty-two cases of rupture of the kidney, treated at the Friedrichshain Hospital, some of them with and some without complications. Most of them had been caused by being run over or by falls from a considerable height, and only one was a case of penetrating wound. Violent pain in the injured side and hæmaturia were constant symptoms in all. The pain was either constant, or it came in paroxysms, caused by blocking of the ureter by blood clots. There was frequently dulness on the injured side. The bloody urine continued a variable length of time, often several days, and in one case twenty-three days. On rare occasions, and the symptom was then a serious one, secondary hæmorrhage came on from the injured kidney.

As regarded prognosis, implication of the peritoneum was of great importance; in seven cases there was pronounced irritation of the peritoneum; but even when the irritation was very marked, it was not proof that the peritoneum was really injured. In two cases operation was performed, on account of increasing anæmia and enlarged area of dulness. In one case the upper end of the viscus was torn completely off; in the second the kidney was ruptured in several places, the parts not adhering together. Both patients died. For the last eleven years no operation had been performed, and an expectant treatment had been adopted, all the cases recovering.

Hr. Hahn then spoke on

SURGERY OF THE SPINAL CORD.

There were four kinds of conditions that led to opera-

tive measures: injuries by puncture, or fracture of the column, with compression of the cord, tumours, and inflammatory affections, especially those of a tuberculous nature.

Of punctured wounds, two cases were of surgical interest, one of the neck, and one of the spinal cord. The first had already been published, but it was the more important as fifteen years had passed since then, and the nervous system now, as then, presented an exact outline. The puncture was between the second and third cervical vertebræ on the right side. The patient presented the symptoms of a Brown-Séquard hemiplegia of that side; the disturbance of sensibility of the other side was not so pronounced. In the third week after the injury there was some movement of the injured side; after three months there was no real paralysis remaining. The present condition was as follows: The right pupil was smaller than the left, the right arm was thin and cyanotic, the coarse power diminished. On the right there was hyperalgesia, on the left the sense of temperature was lowered, touch was accurately localised. This observation confirmed the statement of Enderlen to the effect that the spinal cord cut completely through was not restored perfectly on union taking place.

The second case was admitted into hospital in 1894 with the diagnosis of tumour of the cord. A cicatrix on the back, however, pointed to injury, and the patient admitted that twelve years before he had been stabbed in the back; he had been in good health from that time up to two years ago, then he got occasional pains and weakness in the legs, and for fourteen months he had been unable to walk. At the time of admission he had complete paralysis of the lower extremities; sensibility was extinguished almost up to the umbilicus, there were spasms, the reflexes were exaggerated. Besides the above there was great decubitus.

The injury was suspected to be at the level of the ninth dorsal vertebra, as both the symptoms and the cicatrix pointed to this. On account of free bleeding the operation had to be performed in two sittings. The eighth and ninth vertebral arches were resected, the cord here showed a depression, covered by a white mass. A projection was felt on the body of the vertebra, concerning which it could not be decided whether it was a foreign body (knife blade) or a projection of bone. It could not be removed. No change took place in the condition of the patient after the operation and he died in a short time, and the autopsy showed a firmly fixed foreign body, and the spinal cord softened and band-like at the spot.

In the case of fracture with compression it was always a question as to operation. Statistics did not appear to favour it. He had four cases of fracture treated by operation—one twenty days, one fourteen days, one nine weeks, and one three days after the injury. Only the one operated on nine weeks after the operation improved and was discharged from hospital; he died a year afterwards. The others died, one in fourteen days after the operation, and one six and a-half months, and one nine months after. None recovered, although the fracture was comparatively favourable in all four; in two the bodies of the vertebræ were fractured.

In spite of this, however, he advised operation as early as possible after fracture of the arch, before de-

generation had set in. An exploratory incision should first be made; if no fracture could be found nothing further should be done. If compression was caused by a projecting piece of the body, this could be stripped off. As regarded other conditions, he had twice operated for echinococcus. In the first case the cysts lay from the third to the eighth dorsal vertebrae; they were removed by resection of four vertebral arches. Two days later the patient died; he was already very low and had a large bed-sore. In the second case there was no compression but only irritation of the cord. There was an abscess of the column that contained cysts and had advanced towards the ninth dorsal vertebra. The patient recovered.

Operation was performed three times for supposed tumour. In one case the symptoms pointed to a process connected with the lumbar roots. The operation showed a thickened bony mass but no tumour. Improvement, leading to recovery, took place at once. The other two cases died; one was a case of softening, and one a syringomyelia.

With present aids to diagnosis the level of a tumour was not so difficult to determine, but it was difficult to determine the nature of the growth. It was important to ascertain whether a tumour was intra- or extradural; in the latter case the prognosis was more favourable, and the dura would not be opened and the cerebro-spinal fluid would not escape. In case it was necessary to open the dura it was well to place a temporary circular ligature above the spot to be incised, which would prevent the escape of fluid and would be well borne by the cord. This ligature should not be removed until the incision opening had been carefully closed by suture.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 15th, 1902.

TUBERCULOUS PROPHYLAXIS.

KAUS resumed the discussion on Weichselbaum's paper on tuberculosis. He severely criticised the blue ray treatment of Kaiser, and declared his belief that Kaiser could not have been experimenting with the tuberculous bacillus at all, but probably with some sort of cocci or sarcini, notwithstanding the fact that he got the culture from a sero-therapeutic institute. Recently test trials of Kaiser's method had been made in the institute under his own supervision, with typhoid, cholera, and coli bacilli, with negative result.

Rauch confined his remarks to the "curoste" of Gleichberg in the prophylaxis of tuberculosis. He was in favour of notification and disinfection of tuberculous patients; also the use of the Dettweiler spittoon, a milk steriliser, and a methodical tuberculin test of the cows. He compared the death-rate from 1815 to 1825, showing that the death-rate had fallen since the foundation of the institution in 1835.

Weichselbaum, in reply, said that Rabl was correct in asserting a clinical distinction in scrofula, but he must admit it to be tuberculous in its pathological anatomy. Winternitz, he said, had three points to answer:—(1) Tubercle is widely diffused—Nägele having met with it in 90 per cent.; but we must remember he did not find the bacilli in 90 per cent. only in some of the fluids. These

bacilli may be found in the urine, faeces, and in various cavities of healthy people, but Kitasato had proved that the presence of bacilli in the lung was the true phthisis. (2) Again it is found that in the open sunlight and air no bacilli are to be found, but only in rooms where phthisical patients had resided, therefore some other factor than disposition must be considered. If these were aggregated into one place the danger would be less.

The struggle for the spittoon was not to be dogmatised upon, although the United States sent people to prison for spitting on the floor. The disposition would depend on the virulence and number of bacilli present in proving the contagion to be genuine or abortive. The increase of the toxin would determine the ultimate results.

AN UNUSUAL ACCIDENT.

M. Zuppinger (*Wien. Kl. W.*) gives the following history of a case of pneumothorax in a child. The patient, *æt.* two years and a half, was put to bed in his usual health and fell into a normal sound sleep; some few hours later the household was alarmed by the screams of the child, who was found to be deeply cyanosed and suffering from intense dyspnoea, and covered with a cold sweat.

A little later he was brought to hospital, where it was found that he had pneumothorax of the right side.

Death occurred thirty-six hours after the screaming fit, and at the autopsy it was found that the right lung had been perforated by a wire which was used as the thread of the palliase getting free and piercing the boy's side.

The case is interesting in that the wound produced by the wire was so small that it escaped detection until the autopsy.

EPITHELIOMA AND RÖNTGEN RAYS.

Schiff showed a patient, *æt.* 101, who had been treated for epithelioma of the nose with perfect success after fourteen sittings. Twelve days after this the cicatrix was smooth, firm, and hard. Six months ago the same patient had a similar epithelioma treated with the Röntgen rays which had not since returned, and may be considered cured.

In a second case of lupus exulcerans hypertrophicus he obtained a similar result with the Röntgen rays. The advantage of the Röntgen rays over the Finsen method lies in the rapidity of healing by the former, the Finsen rays being slower in their action.

Schiff suggested that lupus institutions might easily be merged in the present movement of building tuberculous asylums in the country, as the two diseases were so closely associated.

TUBERCLE IN THE ARMY.

Wick next went into statistics and quoted from Franz, of the Bosnian Army, who found that only 61 per cent. of the soldiers reacted to tuberculin. This number, he said, was a very modest estimate considering that it comprehended lupus, caries, otitis, and lymphadenitis tuberculosa. Another important calculation would be the proportion of morbidity to the mortality, which might be done by an examination of all schools and seminaries. Benedikt had made an estimate of adults attacked with tuberculosis in consumption hospitals before special institutions were provided and since they were in operation. The proportion before was only 1.7 per cent., and since their inauguration was

16 per cent. These figures tallied with those in Meran, Gleichenburg, &c.

LUPUS DISSEMINATUS.

Ehrmann next showed a case of lupus disseminatus which had assumed the form of acne. The blue-violet colour and the soft consistence of the efflorescence were conclusive as to diagnosis. It seemed to have spread from a tuberculous centre by the passage of a large number of the bacilli into the capillaries, where they were arrested and started fresh centres of destruction. Along with these lupoid efflorescences were to be found typical tuberculous ulcers. He expressed the opinion that patients with diseased internal organs might take on tuberculosis when otherwise healthy, but lupus must be acquired.

The Operating Theatres.

FRENCH HOSPITAL AND DISPENSARY.

ABDOMINAL HYSTERECTOMY FOR FIBROID UTERUS WITH CYSTIC OVARIES.—Mr. O'CALLAGHAN operated on a woman, æt. 40, who had been first admitted into the medical wards under Dr. Vintras, suffering from irritability of the bladder with frequent micturition. She had very little trouble until a year ago when menstruation became profuse, reducing her to an anæmic and bloodless condition. Her bladder became so irritable that she could not retain her urine for more than an hour unless lying down; she also suffered from constipation, amounting at times almost to obstruction. After consultation, operation being advised, she was transferred to the care of Mr. O'Callaghan. Owing to the patient having to work for her living, and being incapacitated from doing so by these pressure symptoms, which were entirely due to a large fibroid uterus being fixed in the pelvis by adherent tubes and ovaries, it was decided to operate without delay. The abdomen was opened by a four-inch incision in the middle line. This it was found afterwards necessary to increase up to the umbilicus, owing to the difficulty of delivering the uterus out of the pelvis. On both sides of the uterus were two firm ovarian cysts, with hæmato-salpinx, which made the usual steps of the operation much more difficult and tedious. The uterus was first removed at the level of the os, and then enucleation of the cysts was proceeded with; each of the cysts unfortunately ruptured, filling the pelvis with a thick, black, tarry-like fluid; this was mopped up with warm sponges, and the toilet of the peritoneum finished most carefully after the ovaries and appendages had been removed. The peritoneal vault was closed with catgut sutures, no drain being left in the vagina, but owing to the soiling of the peritoneum during the operation it was thought wise to leave a glass drain in Douglas's pouch for twenty-four hours. Mr. O'Callaghan said this was a case which demonstrated the uncertainty which was so apt to be met with in abdominal work; as before operation he had hoped from external examination that this would have been a very simple case, but it was evident to those present (among whom were Mr. Edmund Owen and Dr. Clement Godson) that owing to the difficulties met with the operation turned out a very complicated and tedious one, lasting over an hour, whereas he had hoped to be able to complete it under forty minutes. The condition of things found in this pelvis easily accounted for the pressure symptoms which had made

the patient's life a burden and drove her to seek operative interference, as the enlarged fibroid uterus was bound down by the adherent appendages and tilted forward, infringing on the pubes, and thus occupying all the bladder space, while the cervix was pushed backwards pressing on the bowel, this being increased at times by congestion of the left broad ligament.

Twenty days after operation the patient was sitting up in bed, and in a few days will leave for the French convalescent home at Brighton.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 19, 1902.

DISINFECTION.

THE London County Council is deserving of high praise for the judicious encouragement and wise support which it has granted to scientific research and the vigour and persistence with which it has endeavoured to secure hygienic conditions for the people. Dr. Shirley F. Murphy, the Medical Officer of Health to the London County Council, has just issued a most valuable report containing the result of the investigations of Drs. Klein, Houston, and Gordon as to the value of various methods of disinfection carried out under ordinary conditions as met with in dwelling-houses. The report is deserving of the most careful consideration. Among fluid disinfectants carbolic acid, permanganate of soda, bleaching powder and corrosive sublimate have been tested, while among gaseous disinfectants formalin and sulphurous acid gas have been employed. Seven microbes have been experimented with, organisms representative of highly resistant and less resistant pathogenic forms. Spores of anthrax bacilli, staphylococcus pyogenes aureus, the bacilli of typhoid fever and diphtheria, bacillus pyocyaneus, the vibrio of cholera and the tubercle bacillus. Four different sorts of material were chosen as the bearers of the infective organisms, and such as in ordinary practice would be met with requiring disinfection, namely cloth, unwashed or unpainted wood, linen, and wall-paper. To them the micro-organisms distributed in

broth, in milk, or in melted gelatine, were liberally applied, and the charged materials were then exposed to the various disinfectants. The results are of much practical importance. As regards gaseous disinfectants, it was found that both formalin and sulphurous acid failed in the case of wood and cloth charged with spores. Formalin vapour showed to greater advantage than sulphurous acid in the case of tuberculous sputum dried on linen and paper. As regards fluid disinfectants, corrosive sublimate, 1 in 1,000, with twenty-four hours' exposure, destroyed all microbes, including the spores of anthrax and the tubercle bacilli; carbolic acid in 5 per cent. solution, with twenty-four hours' exposure, failed to destroy anthrax spores, but was efficacious for all others. In the case of Condry's fluid, one teaspoonful to a pint with twenty-four hours' exposure gave a negative result, and even when used in five times that strength was still practically useless. Bleaching powder, generally speaking, only destroyed the less-resistant forms of microbes, though in the case of anthrax spores on paper and on linen, this material proved more effective than carbolic acid. The typhoid bacillus was killed by all the disinfectants except Condry's fluid and bleaching powder. Condry's fluid gave a negative result in each experiment, and bleaching powder for the disinfection of wood and cloth infected with this organism failed with one hour's exposure, but was efficacious on twenty-four hours' exposure. The bacillus diphtheriæ was killed by formalin and sulphur di-oxide. The vibrio of cholera was in each experiment destroyed by all the disinfectants except Condry's fluid and bleaching powder. Staphylococcus aureus was also killed in each experiment by all except Condry's fluid and bleaching powder. Anthrax spores were only destroyed with certainty by perchloride of mercury, the other disinfectants either failing on each occasion or being uncertain and almost invariably failing when wood and cloth were the materials to be disinfected. For tubercle bacilli carbolic acid and perchloride of mercury were the only disinfectants efficacious on each occasion; Condry's fluid and sulphur di-oxide were of negative value, and the other disinfectants untrustworthy. It is interesting to note that neither formalin nor sulphur di-oxide were efficacious for the wood or cloth infected with this bacillus. This authoritative report will be of great value to sanitary authorities. Unfortunately the truth regarding the relative value of the various germicides has been much confounded by the pernicious custom of certain would-be pathologists and chemists who prostitute their profession in order to sing the praises of certain preparations widely advertised by disinfectant manufacturers. We strongly condemn the action of any so-called scientist who agrees to allow his services to be retained in the interests of any proprietary article, disinfectant or otherwise. It is therefore particularly interesting to have such a report as the present one, and we trust the London County Council will continue such an admirable method of securing the best and most trustworthy

information on medical and hygienic questions as the appointment of special investigators.

THE HOUSING QUESTION.

THE attention of the Government of the United Kingdom is so occupied at the present moment with affairs of "imperial" interest that there has been for several years past little time to attend to social reforms at home that are merely of national importance. Chief among these questions that urgently call for legislation is that of the housing of the working classes in the great towns of the Kingdom. This matter lies at the root of progress in public health and in public morality, to say nothing of the importance of maintaining a decent standard of physical development and vitality among the workers who form the backbone of the wealth, of the administration and of the defence of the country. The sums expended by various local authorities throughout the kingdom show that the urgency of the problem has been generally recognised. Half a million of money goes only a small way in purchasing sites and erecting dwellings. When a year ago the London County Council decided upon spending that amount upon carrying out a scheme of the kind at Tooting, it was pointed out that whereas 12,000 persons would be thereby provided for, yet, on the other hand, the normal increase of population for London in a single year amounted to 30,000. As regards legislation the whole matter still waits to be handled in a broad and statesmanlike manner. The fatal defect of the Act of 1890 was its cumbrous and costly machinery, which always rendered it practically a dead letter so far as medical officers of health were concerned. Mr. Chaplin's Bill of 1900 registered one advance by enabling the local authorities of the metropolis to buy land outside their own districts for the purpose of carrying out housing schemes. A year ago it was stated in the House of Commons that in London alone there were 30,000 people living at the rate of six in a room; 9,000 at the rate of seven in a room; and 3,000 more at the rate of eight in a room. That fact is in itself more than sufficient to justify the demand for a drastic and immediate treatment of the whole question. Lord Cross, a kindly man, spoke last week upon the housing problem at a Poor-Law Conference in London. He very rightly observed that a great point in this matter was to secure proper provision for people of the poorer class, and at the same time to avoid pauperisation and demoralisation. He believed sufficient means existed, but that efficient administration was required rather than fresh legislation. With all due respect we may point out to Lord Cross that his views are in direct opposition to the convictions of, we should imagine, every medical officer of health in the United Kingdom. The existing Housing Acts have proved an abject failure when tested by the simple question as to whether they have or have not achieved the object for which they were called into existence. The overcrowding of great towns is going

on space, and is every year being multiplied automatically by the natural increase of population. The only people who thrive on the overcrowding of urban populations are the landlords, whose rents are inflated to a fictitious value in direct proportion to the degree of overcrowding. As an example may be cited the enormous rise in rents that has taken place in the East End of London during the past ten or fifteen years. The increase of small tenement rooms of the great towns generally during the past few years has probably ranged from twenty to fifty per cent. or more. The fact that landlordism lies at the back of the question is being gradually more and more recognised by all classes of society. The landlord is not only able to avoid his just share of the liabilities of local taxation, but he often evades his responsibility as regards the sanitary condition of his property. In coming legislation the landlords will take care to secure full compensation for any property they may be compelled to sell to the local authority upon an inflated basis that has been founded upon the damaged lives and the misery of the poorer classes. Beyond a doubt, as we have long since said, the cost of land, its burden of ground rent, and its extortionate house rent will have to be grappled with before the problem of the housing of the working classes can be satisfactorily settled. Meanwhile, every large suburb of every large town is creating its own housing difficulty, so that the day of universal wringing of hands cannot be long deferred. The statesman who arises to settle this question will be more entitled to the thanks of his countrymen than any costly and showy champion of imperial interests in remote parts of the world.

QUACK REMEDIES.

We heartily welcome the expression of opinion of the County Amagh Grand Jury on quack medicines which they made during the present Spring Assizes to Mr. Justice Wright through their foreman, Sir James H. Stronge, Bart. Their condemnation met with the approval of that distinguished judge, and will be acceptable to all men who desire the welfare and happiness of the community. In the winter of 1898 some of the more notorious offenders were laid by the heels and are still doing "time" for their fraudulent practices. One group of defendants pleaded "not guilty," sheltering themselves under the ingenious excuse that they never sent any medicines in return for the money. They advertised in almost all the religious and sporting papers, and their usual lure was that a 31s. 6d. packet of their drugs produced the desired results. When the poor gull sent the 31s. 6d. he got a long list of questions to answer, and when he or she complied with this request there came the opinion that the nature of the illness was so serious that the medicine should be continued for some time, and that it should be a somewhat stronger than the ordinary mixture. A quantity of the medicine of the necessary quality would cost £5 5s. Then the correspon-

dence ceased, and if, as sometimes happened, the buyer became indignant at getting nothing for his money, and threatened proceedings, he was informed that the vendors were reluctantly forced to the conclusion that the drugs were intended for an unlawful purpose and if they got any more annoyance they would hand over the whole correspondence to the police authorities. We quote this from the open proceedings in court and we have no reason to suppose that they were not generally known to newspaper proprietors of both religious and sporting papers. Many are the disguises of the advertising quack who lives by playing on the fears and gullibility of the unfortunate victims of illegitimate pregnancy. One callous ruffian advertised pills that should not be taken during pregnancy as they were "likely to cause abortion"; for twelve soap and aloes pills bearing the above caution, this Shylock charged 4s. 6d. a box, and sold the boxes by the gross. The game appears to be so very profitable to quacks and newspaper proprietors that there is little hope of its being discontinued. We had hoped that the 1898 exposures of the ways of the quacks and the utter worthlessness of their remedies would have a salutary effect, but no good has resulted from the then action of the Executive, and it almost seems hopeless to try to rouse the authorities again into activity. We would, however, suggest that the printer and publisher of any newspaper, pamphlet, circular, magazine, or printed matter advertising any commodity likely to facilitate the commission of an illegal act of the class or character of miscarriage or abortion shall be on conviction imprisoned for a period of not less than one month or more than twelve months. Religious journals are the worst offenders, but the political journals are among "the first three," and the proprietor of a up-to-date political paper who professes to read between the lines of every manifesto of his own or the opposite party may be credited with sufficient acumen to see the hand of Esau, and yet recognise the voice of Jacob deceiving the feeble and the blind. It is intolerable that a brood of avaricious newspaper proprietors be allowed to fatten on such ungodly and unmerciful gains. A common thief is sent to jail, every man approving of his committal. If a receiver has facilitated his converting his ill-gotten gains into money the receiver, if caught, is also liable to a term of imprisonment. It strikes us that the newspaper proprietor who inserts the advertisement plays the same rôle to the quack vendor as the receiver to the thief, and merits the same punishment. If the law were so interpreted our religious papers would become clean and our sporting ones reformed. In this matter as in many others our great contemporary, *The Times*, has given an example of cleanliness that is an ideal standard.

THE King has promised his patronage and that of the Queen to the grand bazaar which is to be held at the French Embassy on June 10th and 11th next, in aid of French charities in London.

Notes on Current Topics.

Small-pox in London.

ONCE more the steady progress of small-pox has to be recorded in London. Cases are being reported from various parts of the United Kingdom. Manchester is said to be now free, but Salford is still infected. The medical officer of the workhouse at the latter place, referring to a recent case of small-pox in the casual ward, pointed out the inconsistency of paying large sums of money to vaccinate the outside public while a mass of unprotected persons were crowded together in the workhouse. The disease has spread at Ashton-under-Lyne, numerous cases have occurred at North Shields; twenty-one cases have been notified at Nelson; thirteen at Bury St. Edmunds; while many cases continue to be reported at Swansea. The Metropolitan Asylums Board has apparently come round to the view of the disease taken for some months past by THE MEDICAL PRESS AND CIRCULAR, namely, that the present outbreak is likely to be of very serious dimensions. At a meeting last week the Chairman of the Ambulance Committee spoke of it as being practically certain that the epidemic would continue through the whole of next winter, with the probability of an increase in severity. It has been decided to establish an adequate road ambulance service in case of any breakdown in the river steam-boat organisation owing to fog or other circumstances. The flood of anti-vaccinationist correspondence to the newspapers continues in unabated stream. It is really somewhat disheartening to find a gentleman writing from a county vicarage to submit the proposition that small-pox is not epidemic and not infectious; that its cause is *ab intra* and not *ab extra*; and that it can be cured by "a natural and simple method." The reverend gentleman does not enlighten us as to the nature of his therapeutics. In Glasgow the disease continues to extend, and a total of 202 cases were under treatment on March 10th. With regard to the recently-organised system of free medical consultations in doubtful cases of sickness in the Metropolis, Dr. Sykes, Medical Officer of St. Pancras, has reported that during the past thirteen weeks about one-half of the doubtful cases of fever or eruption examined were found to be cases of small-pox, about one-fourth cases of chicken-pox, and the remaining fourth distributed among a number of other conditions. On Tuesday, the 11th, there were 76 fresh cases of small-pox reported in London; on the 12th, 52; on the 15th, 43; on the 16th, 45. The total number of cases under treatment at midnight on Saturday last was 1,565. Since the beginning of the outbreak there have been 766 deaths from small-pox. During the past week the deaths registered from that cause in London were 80, which is a greater number than any hitherto recorded in a similar period. Of those who died 43 were vaccinated, but no information is given by the Registrar-General as to revaccination.

Hospital Consultants and Out-patients.

A LAY correspondent of one of the London daily newspapers recently invoked the "powerful aid" of the Editor in removing a source of great pain and discomfort to a steadily increasing number of the community. This flourish of trumpets referred the "almost brutal" manner of speaking to out-patients adopted by some of the hospital doctors. Logically speaking, the description raises no issue for argument, as the action complained of must be either brutal or not brutal, and almost brutal is the same as not brutal. However, the complainant apparently means quite brutal, for he goes on to say that in a hospital not far from the Edgware Road he heard a week ago two doctors speak to patient after patient in a manner which would have raised a mutiny in a prison. One observer made the curious remark that he "thought it unlikely the Creator would thus address a blackbeetle." Surely this is not meant to illustrate the relative position of hospital consultants and out-patients. The correspondent further states that in the same room was another doctor, and it was "a pleasure to hear his sympathetic and gentlemanly remarks." It may be at once admitted that all consultants of experience have a sharp quick way of getting at the facts of a case. Many of them are busy, over-worked men who have to get through the drudgery of seeing perhaps fifty or a hundred out-patients. The only way of doing so is to take them at the rate of twenty or thirty in an hour, a speed which leaves no time for pleasant conversation, however desirable that might be to relieve the dreariness of the out-patient room. It is the system that should be blamed, not the men who have to administer it. To our mind the swarm of out-patients should be reduced to the few that really want consultant opinion besides private medical advice.

Acetylene as an Illuminant.

IN view of the gradual extension of the use of acetylene as an illuminant, the question of its effects upon the human organism becomes of actual interest. The mere fact that, as usually met with, it possesses a disgusting odour, is assumed by many to justify the assumption that its presence in the air, even in comparatively small quantities, is likely to be attended by disastrous consequences. Now the disagreeable nature of the odour of acetylene has been shown to be in large measure due to the admixture of the gas with various impurities, foremost among which are phosphoretted and sulphuretted hydrogen, gases which exert a well-marked deleterious action when breathed in certain proportions. As a matter of fact it requires a tolerably large proportion even of the impure gas to produce tangible effects of a pathological character, and means are at present available for eliminating the actively injurious constituents of the gas prepared from calcium carbide, so that the risk of injury is reduced to a minimum. It is only in the case of portable lamps that any risk of the kind may

be said to occur, and only because it has hitherto been found difficult to so regulate the output as to avoid leakage. When produced in a proper gasometer with appropriate fittings no such leakage is to be feared, or if any does occur it is in the open air where it can do no harm. Doubtless as our experience of this new illuminant increases we shall obtain more accurate data upon which to proceed but in the interest of a cheap and unrivalled source of light it is desirable to accept stories of alleged injurious effects with caution.

The Diploma of the Spectacle Makers Company.

THE Master of the Spectacle Makers Company which, like most other City companies, comprises but an infinitesimal minority of the particular calling, points out that the diploma granted after examination by his company in no wise authorises opticians undertaking sight testing. The examination in fact bears on theoretical and applied optics and trade technique, in other words, it simply seeks to ensure that the diplomates shall have an intelligent knowledge of their calling. It has been urged that sight testing is after all a tolerably simple matter which can be mastered by any intelligent tradesman with a moderate amount of study and experience. Even if this fallacious hypothesis be conceded the fact remains that in many instances persons with failing vision who apply to the optician for glasses are in reality suffering from some form of disease of the organ of vision or from some constitutional disease with visual manifestations, calling for appropriate treatment. This occult cause of failing vision would of a certainty escape recognition at the hands of the mere tradesman whose object in life is to sell as many pairs of spectacles as he can at as high a price as the appearance of the applicant seems to warrant. No amount of experience or casual training will enable the rule-of-thumb man to diagnose these conditions, and in a certain proportion of cases material harm must accrue to the sufferer, who of course is as ignorant of the cause of his trouble as the optician to whom he applies.

The Case for Vaccination.

UNDER this title an excellent little book has just been published by Messrs. Baillière, Tindall, and Cox, the author being Mr. E. Brown, L.R.C.P., M.R.C.S. It is addressed mainly to the public, but the facts and figures which are judiciously marshalled may possibly prove of service to the medical practitioner who, it is to be feared, is not always as well posted as he might and should be in regard to the salient facts upon which the practice of vaccination as a prophylactic of small-pox is based. The great obstacle to the more general adoption of vaccination is the ignorance of the general public on the matters at issue, and we know that when the reason is weak the prejudice is strong. The author mentions as one reason of the unpopularity of vaccination among the lower classes, the attitude of medical men who are but too apt to regard the question of vaccination as

chose jugée, and to refuse to enter upon any discussion of its merits. This, however, is a case in which the old precept to give our decision but not our reasons would be more honoured in the breach than in the observance. Doubtless those alone who have received a medical training are competent to form a trustworthy opinion, but this fact does not militate against their seeking to influence those with whom they come into contact by convincing argument, couched in terms likely to be understood of the people. This little book will furnish them with the necessary data, and as it is sold at one shilling it ought to have a wide circulation at the present juncture.

Should the Arm be Bandaged After Excision of the Breast?

THE methods of operating in cases of cancer of the breast have been long and ably discussed. Champions have proudly maintained the honour and glory of special procedures. The first to propose has been quickly followed by the first to perform and he in turn has been hotly chased by the one who claims to have perfected, and so proceeds the merry dance. This is desirable for healthy emulation, and is productive of much good. The question of post-operative detail in such cases, in so far as the position of the arm is concerned, has been lately exhaustively argued by Mr. Thomas Carwardine, of Bristol. It is surprising to find that he thinks the practice of fixing the arm to the side after excision of the breast is universally adopted. This detail has been long given up in many places, so much so that probably there are many young qualified men who have never seen it done. In the article we have referred to it is stated that (a) "the fancy remains as a fetish," and, that why it should be retained, it is scarcely possible to say. The suggestion is made that perhaps it was thought that movement caused suppuration. The more obvious explanation seems to be that the abducted position was thought to promote the retention and accumulation of blood, and hence favour delay in union. It is not suggested that Mr. Carwardine's paper will not be received with disfavour in some centres of surgical teaching; for in Senn's recent work on tumours it is directed that the arm be bound to the side. Nevertheless, we can assure Mr. Carwardine the practice he has so ably advocated is being and has long been carried out by others, who will gladly welcome the appearance of his very able exposition, so clearly and logically expressed.

Clinical Pathology.

MANY of the older practitioners, it cannot be denied, are in ignorance as to the possibilities and limitations of diagnosis by purely pathological methods of research. Dr. Stuart McDonald, in a valuable paper in the current number of the *Scottish Medical and Surgical Journal*, which might be studied with advantage by every practitioner, shows that there are two classes of men who not infrequently invoke the aid of the pathologist. First,

those who demand impossibilities; and second, those who make no endeavour to conceal their doubts as to the ability or usefulness of pathological investigation to aid practical medicine. Of course a middle path is the only wise and just one. It is necessary that a pathologist's report should be used as a guide, but not to be followed implicitly. At the present time so much attention is often devoted to the non-essentials of the curriculum, that there is danger of neglecting the training in the conduct and interpretation of the procedures and results of clinical pathology. We venture to think that special attention should be given in the post-graduate schools, now becoming so popular, to a practical study of methods of pathological investigation specially applicable to clinical medicine.

Scottish University Malcontents.

It is extremely difficult for anyone not brought up in the atmosphere of a particular University or school of medicine to appreciate points raised in connection with its curriculum or management, and few have had the opportunity of being thus brought intimately in contact with more than one University. It is on this account that the average man finds it hard to judge of the merits of the charges which are being so frequently made, and with such energy, against the whole conduct of affairs at Glasgow and Edinburgh Universities. The *Edinburgh Medical Journal* for this month contains a plea "for something more than a mere living wage for University assistants," "free trade for intellect and a fair remuneration," the appointment of a larger number of extra-academical examiners for graduation, that an age limit should be fixed for the occupancy of chairs, &c. Malcontents will scarcely be satisfied to be told that at other than Scotch seats of learning a living wage for assistants is not universally given. An appeal is made to the *undergraduate* to institute certain reforms apparently by force of combination, and a promise is made that the way in which reforms may be enforced will be pointed out in future pages.

Arsenicated Beer.

THE recent experience at Halifax, to which we alluded in a former number of THE MEDICAL PRESS, would seem to show that the beer of the North of England is still not altogether free from dangerous quantities of arsenic. Evidence presented to the Royal Commission at its recent meeting would, however, go to prove that such manifestations as peripheral neuritis and dilatation of the heart from myocardial degeneration are now comparatively rare in Manchester and district. All this would seem to favour the view expressed by many investigators that probably arsenic has for long been an important factor in the production of so-called "alcoholic" lesions in that part of the country, but it is manifestly illogical and unscientific to contend, as some seem inclined to do, that there is no such affection as alcoholic neuritis. A very complete *resumé* of the subject of arsenical poisoning

from beer contaminated by arsenic is furnished by Dr. T. N. Kelynaek in the recently issued volume of the "Medical Annual." The article is well illustrated, is furnished with useful references, and is likely to be of service to those interested in the subject.

The "Great Coat" in Modern Life.

OF recent years the fashion of walking out in the winter months without a "top" or "great" coat has waxed and multiplied among men. One of the results of the campaign in South Africa has been to emphasise this assumption of hardiness. From a medical no less than from a common sense point of view it may be pointed out that what is natural out on the veldt may be risky and unnecessary here at home in the streets of our great towns. In the one case a man is in perfect training and gets plenty of exercise, whereas in a town his pursuits and pleasures are often of a flabby and sedentary nature, and it is difficult to obtain out-of-door recreation. Under these circumstances the circulation becomes depressed and the body is less able to withstand sudden exposure to cold, so that the extra outside coat assumes a position of great importance as a kind of compensation balance to maintain an equable temperature of the body. Perhaps one of the most fixed characteristics of mankind, certainly the one that enables him alone of mammals to claim the whole world, regardless of the rigours of climate, as his own, is the power of regulating the thickness of his clothing. Calico in the tropics and thick furs in the frozen regions are extreme instances in point. Under modern social conditions in the United Kingdom he has to face extremes not only of season but also of in- and out-door temperatures. What reasonable man, were he strong as Hercules, would drive home from a hot theatre in mid-winter without an extra wrap in the shape of a top coat?

Tobacco and Old Age.

THE use of tobacco at any time of life is a vexed question, to say nothing of the doubt whether it should be sanctioned after the advent of old age. In most things appertaining to the latter half of life there is a kind of instinctive regulation of the means whereby life is sustained on the one hand and made tolerable on the other. Thus a man drops the severer sports in favour of golf and cycling and rowing, and games that are not too exacting for the heart and the muscles. So is it also with eating and drinking. A wise man curtails the pleasures of the table, that is to say, if he wish to carry his existence into the confines of the sere and yellow leaf. The question naturally arises, what is he to do in the matter of tobacco? Most men settle the question for themselves by dropping their pipes and cigars—old men rarely smoke cigarettes—when they have got well past middle age. The heart, when it begins to show signs of wear, bears the depressant action of tobacco badly. Hence, many a heavy smoker at thirty is a total abstainer from tobacco at sixty. Yet the healthy old

man can smoke to the last day of his life, even though that take place several years after he has passed the century. Many instances are on record where centenarians, both men and women, have smoked or taken snuff regularly year in and year out to the end of the chapter. So that we must conclude the regular use of tobacco is not incompatible either with the attainment or the enjoyment of longevity. Much the same line of reasoning—with all due deference to our temperance friends—applies to the use of alcohol; not, however, be it carefully noted, to its abuse.

Alleged Benefit Society Frauds.

A CASE of direct interest to medical practitioners generally throughout the kingdom was partly heard last week in a London police court. As the case is still *sub judice*, obviously no comment can here be offered, but at the same time a few general considerations of extreme importance suggest themselves apart from the truth or otherwise of the particular charges brought forward. The evidence for the prosecution stated that the defendant joined a benefit society and went on the sick list on account of rheumatism and lumbago for several months. During the period he was drawing sickness pay he was alleged to have joined two other friendly societies and to have produced evidence that he was in good health. His position, therefore, was that of holding medical certificates on the one hand, that he was ill and unable to work, and on the other that he was in robust health. It is clear that if such were the facts the medical men have been tricked on one side or the other, or perhaps on both. The danger of being made the catpaw in roguery of the kind indicated is ever present in medical attendance upon sick club patients. To the honour of the working classes of this country it may be said, however, that frauds of the kind under discussion are of rare occurrence. Now and then they are undoubtedly perpetrated, and can only be detected by constant vigilance on the part of the friendly societies and their medical officers. As fraudulent claims are nearly always associated with multiple assurances, it would be well to furnish the medical attendants with a list of all such members, and to keep the particulars posted up to date from time to time.

The Meat of Diseased Animals.

THERE can be no more cruel fraud practised upon the public than that which palms off upon them meat that is tuberculous, or in other ways unfit for food. The evil is absolutely preventable, for skilled inspection is able to detect at sight those conditions of disease that fall within the present roughly-defined naked eye, appearances warranting the destruction of the whole or of part of a carcass. From a scientific point of view it may be doubted whether the permission to sell any part of an animal organically affected with tuberculosis is not fraught with danger. However, the meat trade can now invoke the support of Professor Koch upon that point, whereas the sanitarian must patiently await the verdict of the Tubercu-

culosis Commission's investigation at Stanstead farms as to the communicability or otherwise of tuberculous disease from the lower animals to man. Fortunately, in a great number of instances the condition of a carcass demands no discussion as to abstract questions, but it may be condemned forthwith, so to speak, on its demerits. Last week a Peterborough farmer was summoned for sending to the London market the carcass of a tuberculous cow whose lungs were adherent to the chest wall on both sides. The Guildhall magistrate imposed a fine of £80 and four guineas costs or two months' imprisonment. The bad meat convictions in the Metropolis within the past two or three years have been many, and the punishments most exemplary, either heavy fines or imprisonment without option of fine being inflicted. By a wise move the burden has been shifted to the shoulders of the county butcher or farmer, who is at the root of the mischief. This example might be followed with advantage in all parts of Great Britain and Ireland.

Gelatine as a Therapeutical Agent.

THE value of subcutaneous injections of gelatine in enhancing the plasticity of the blood has been established, although the method of treatment has not so far come into general use. It would be of especial interest to try its effect in a number of well-marked cases of hæmophilia, the number of recorded experiments of the kind being small, and, therefore, inconclusive. It has been pointed out that glycosuria, albuminuria, and other similar conditions are due to variations in the cryoscopic properties of the blood, and it is suggested that the deleterious effects which the altered blood ultimately determines on the liver, the kidneys, and the capillaries might be prevented or recovered from if the normal plasticity of the blood were restored by the administration of an aqueous solution of gelatine by the mouth or otherwise. According to Dr. Lombard, of Paris, noteworthy effects have followed the ingestion of half an ounce of gelatine a day, and the method is simple and innocuous enough to command a trial.

Ventilation as a Prevention of Respiratory Disease.

MUCH disease of the respiratory organs arises from a neglect of adequate ventilation. Under our artificial conditions of life it is particularly difficult to avoid the breathing of atmospheres laden with organic impurity. Much might, however, be done to mitigate the evil. Dr. Arthur Ransome ("Tuberculosis," Jan., 1902,) endeavours to show the need of a standard of efficient ventilation in all work-places and such centres of public assembly as theatres, concert-rooms, churches, chapels, and rooms in which meetings are held. In our efforts to establish sanatoria for the afflicted it is necessary to safeguard the relatively healthy, for "there can be little doubt that consumption is kept up to its present high mark by the tuberculous dust which now circulates in the air sewage of these places, and it is high time that steps were taken to rid ourselves of this oppro-

brium." The ardent advocates of locomotion along underground tubes will do well to consider the practical aspect of Dr. Ransome's paper.

The Cerebellum and "Libido Sexualis."

DR. BERNARD HOLLANDER, in his recent ambitious and suggestive, but not very convincing, work on the mental functions of the brain, endeavours to explain why Gall, and phrenologists since his time, have insisted on the association of sexual desire with the cerebellum. Dr. Head is quoted as affirming that pain and tenderness is referred to the occiput in diseases of the ovaries and testicles. Dr. Austin Flint is also reported as having observed persistent priapism and manifest exaggeration of the sexual appetite in cases of disease or injury of the cerebellum. Dr. Carpenter is also quoted where he says: "The circumstances that great application to gymnastic exercises diminishes for a time the sexual vigour, and even totally suspends desire, seems worthy of consideration in reference to such a view; for if the cerebellum be really connected with both kinds of functions, it does not seem unreasonable that the excessive employment of it upon one should diminish its energy in regard to the other." Evidently there is much work for the scientific physiologist to confirm or contradict the suggestions of the phrenologist.

John Parkinson, Botanist.

IN the first number of our elegant and welcome contemporary, *The Country*, which should appeal to all lovers of rural life, there is an interesting article concerning John Parkinson, who lived in the reigns of Elizabeth, James I., and Charles I. His "*Theatrum Botanicum*," which he called his "man-like" work of herbs and plants as contrasted with the earlier "feminine" one of flowers, was published in 1640, when he was 73 years of age. Parkinson, we understand, had a garden in Long Acre, which locality would appear to have furnished material for the medicine chests of our Elizabethan and Jacobean apothecaries. Parkinson was appointed Royal Apothecary to James I., and Charles I. conferred on him the title of "*Botanicus Regius Primarius*." It is interesting to recall the memory of one who was considered worthy of "*A Triumphall Evergreene Lawrell Crowne*."

Professor Niels R. Finsen.

THE name of Finsen is known throughout the medical world, but few are acquainted with the personality of this great Copenhagen physician. Miss Margaret Thomas, in her recently published work, "*Denmark, Past and Present*," gives a portrait of Dr. Finsen and a description of his institution for the cure of lupus at Gammelstofsgrade. Finsen was born in the Faroe Islands, where his father was then Governor, in 1860. He belongs to one of the noblest Icelandic families. His education was commenced at the College of Rejksjvile, whence he proceeded to the University of Copenhagen. The Danish Government have had wisdom to actively

support Finsen in his beneficent work, which has just brought honour and distinction to Denmark.

Nerve-Deafness.

THE attention of British otologists has of recent years been so rivetted on the treatment of suppurative disease of the middle ear and its dangerous sequelæ that the many non-purulent affections of the middle and internal ear interfering mainly with the natural function—that of hearing—have received comparatively little consideration. It is refreshing to note that in the British Laryngological, Rhinological and Otological Association a discussion has taken place on the diagnosis and treatment of various forms of nerve-deafness, on a paper by Dr. Dundas Grant, which we hope to publish in our next issue. The auditory nerve is an extremely sensitive part of the nervous system, and it is not surprising that it should suffer, as the enumeration of the varieties of nerve-deafness plainly shows, in the course of various constitutional disturbances. We note among other forms the anæmic, congestive, hæmorrhagic, hysterical, parotitic, syphilitic, senile, "occupation," toxic, neo-marital, and neurasthenic. It is obvious that without discriminating diagnosis of the varieties the treatment of nerve-deafness as such cannot be rationally carried out. The adjourned discussion will no doubt prove of great practical value.

The Prohibition of Promiscuous Expectoration.

THE Glamorganshire County Council is evidently a body abreast of the times. At last week's meeting of that body a bye-law was adopted, subject to the approval of the Home Secretary, forbidding spitting on the floor of public carriages, public buildings, theatres and shops, under a penalty of £5. We see no reason why this proposed bye-law should not be sanctioned, the more so because, if sanctioned, the praiseworthy example set by the Glamorganshire County Council is likely to be very generally followed by other administrative bodies all over the country. This reform has been "in the air" for some time, and now that public opinion has been educated to a sense of the impropriety and danger of this disgusting habit, we firmly believe that the public would cordially assist in rendering the law operative.

The Government and Cancer Research.

A STATEMENT has found its way into the Press to the effect that the Government is not favourable to the idea of appointing a Royal Commission to investigate the problem of the origin, spread and prevention of cancer. It is, however, reported to be "highly probable" that Mr. Balfour will ask Parliament to make a grant of public money in aid of the scheme of research formulated by the Royal Colleges of London. This course would certainly hold out greater promise than any mere inquiry of available data, indeed it would be difficult to conceive an undertaking less adapted for investigation by a Royal Commission than such a complicated subject as the one under consideration.

A Memorial to Sir William McCormac.

STEPS are being taken by the medical staff of St. Thomas's Hospital to promote a fund for the purpose of erecting a lasting memorial of the many years' connection of the late Sir William McCormac with that institution. The present idea is to place a bust in the central hall and, should the amount subscribed permit, some further mode of commemorating his services will be devised in connection with the hospital.

A Sale of Poisons Exemption Act.

A BILL is shortly to be introduced into Parliament by Sir Herbert Maxwell to protect agriculturists and horticulturists against proceedings under the Pharmacy Acts for the sale of various poisons, and in anticipation thereof a petition has been drawn up and presented in its favour. The petition is a trifle premature seeing that the Bill is still *in posse*, and in any event it is to be hoped nothing will be done in the direction of relaxing the law regulating the sale of poisonous substances; indeed, if legislation be demanded, it ought to be in the opposite direction.

At a recent meeting of a district council near Birmingham, one member boldly moved a resolution in favour of the repeal of the Vaccination Acts as a whole, on the ground that, without being in any sense a preventive of small-pox, vaccination was injurious to the human system. Dr. Tibbetts, the medical officer of health, was ready with a very telling rejoinder, to the effect that the only member of the proposer's household who had contracted small-pox was the one who had not been vaccinated, and this allegation the proposer was unable to contradict.

THE death is announced of Surgeon-General Theobalds, late of Weston-super-Mare, at the age of 80. Surgeon-General Theobalds had a long and active career, having entered the Indian Medical Staff in 1848 at the age of 26. He retired in 1880 after thirty-two years' service, having in the meantime done much active work. He was in India during the great mutiny, and subsequently was chief medical officer to various hospitals. He took the keenest interest in the management of the local Christian and medical charities.

WE regret to have to record the death of Dr. Hugh Fraser, a graduate of the University of Aberdeen, who succumbed to an attack of typhoid fever, at Bethulie, South Africa, on the 4th inst. Dr. Fraser left England four years ago to practise at King Williamstown, but a few months since he accepted the post of medical officer at the Bethulie camp.

PERSONAL.

DR. JAMES HARPER has been elected an Esquire under the order of the Hospital of St. John of Jerusalem in England.

At last week's investiture at St. James' Palace

Sisters Waterhouse, Nixon and Bidmead were decorated by the King with the Royal Red Cross in recognition of the services rendered by them at the front.

MR. HENRY N. CUSTANCE, who has acted as Secretary of the Metropolitan Hospital Sunday Fund for the last twenty-nine years, having resigned owing to ill health, Sir Edmund Hay Currie has accepted the office.

DR. W. CHEYNE WILSON, M.D. Edin., has been appointed Physician to the South Devon and East Cornwall Hospital. He is to have charge of the X-ray department which is about to be established there.

DR. H. C. DRURY, F.R.C.P.I., has been appointed a Visiting Physician to Sir P. Dun's Hospital, vice the recently-elected Professor of Institutes of Medicine, who has been exempted by the College from his hospital duties.

DR. G. NORMAN MEACHEN, Clinical Assistant to the Hospital for Diseases of the Skin, Blackfriars, has been appointed Honorary Physician in Charge of the newly recognised department for Diseases of the Skin at the Tottenham Hospital.

SIR THOS. BARLOW, Bart., M.D., Sir Wm. Church, Bart., M.D., Sir J. Reid, Bart., M.D., Sir Henry Thompson, Bart., M.D., Sir Francis Laking, M.D., and Mr. Alfred Fripp, C.B., F.R.C.S., had the honour of an invitation to the first Court held by his Majesty the King on Friday last.

MR. ARTHUR EVANS, M.D. Lond., M.S. Lond., F.R.C.S. Eng., has been appointed assistant surgeon to Westminster Hospital. Dr. Evans, whilst he was attached to the Yeomanry Hospital in South Africa, was taken prisoner by the Boers under De Wet, but subsequently released.

DR. LOUIS COBBETT and Dr. E. S. St. Barbe Sladen have been appointed by the Royal Commission on Tuberculosis to assist in the experimental work of the Commission to be carried out at Stanstead. They will reside on the farms and devote the whole of their time to the investigations.

THEIR Royal Highnesses the Prince and Princess of Wales paid a private visit to Guy's Hospital on Saturday last, inspecting the wards and other departments of the institution; after which they expressed to the treasurer their satisfaction on the great progress made in the work of renovation and reconstruction since their previous visit.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

THE UNIVERSITIES AND THE CARNEGIE TRUST.

Edinburgh.—A statement, the main points of which are summarised in the following, has been laid before the Trustees by the University authorities. The most clamant need of the University is a building for natural philosophy and engineering, and the Trustees are asked to set aside a sum of £8,000 annually for five years as a contribution to a fund about to be raised for the purpose of purchasing ground for University extension, and, in the first instance, for the erection of laboratories and class-rooms for the teaching of these two

subjects. The library is the second department for which help is demanded; £500 annually for five years to be devoted to structural improvements and £1,500 annually for general purposes. A grant of £2,500 is also asked for the forthcoming year, to be expended on equipment of the museums and laboratories of natural philosophy, geology, botany, zoology, anatomy, pathology, physiology, clinical medicine, and clinical surgery. The Court, recognising the importance of research scholarships, ask that a sum of £1,000 be placed at their disposal to that end in the forthcoming year. Application is also made for an annual grant of £4,000 for maintenance and extension of teaching and research in the various scientific laboratories, and towards payment of the salaries of the increased number of demonstrators, &c., required. As it is advisable that the following lectureships should be erected into professorships—French, German, applied mathematics, insanity, and ophthalmology—and as outside assistance might be available for the endowment of one or more of these chairs, the Court ask the Trustees to indicate in what manner they are prepared to aid in this object. The same applies to certain new lectureships in medicine, science, and commercial education, which the Court are very desirous of instituting. These claims may be summarised as requests for a capital sum of £45,000, and an annual allowance of £9,000, irrespective of what the Trustees feel disposed to contribute to the foundation of the new chairs referred to in the preceding paragraph.

Aberdeen.—The Court point out that this University is the most sparingly-endowed of all the Scotch Universities, and this is especially true of the general fund, which has only some £16,000 of capital at its disposal, and does not benefit by any surplus revenue from the fee fund. In illustration of the smallness of the resources of the University it is stated that for the maintenance of its laboratories and museums, and the provision of materials and apparatus for teaching and research, the sum available during the past financial year was only £1,168. A large extension scheme has been in progress for the past ten years, and all the departments of medicine and science, except physiology and geology, are now sufficiently housed. For these and other subjects accommodation is still required, and this the Court hope soon to be in a position to provide. With the completion of the proposed building the total sum raised and expended by the University will amount to £188,000. The Carnegie Trustees are asked to complete the endowment of a number of chairs, and to found numerous new lectureships and chairs, some of which are being carried on with the sole remuneration of the class fees, as a temporary arrangement. For this it is estimated that from £8,000 to £10,000 a year is required. From £1,500 to £2,000 annually is asked for research scholarships, and for other purposes £9,000 a year. A capital sum of £12,000 is also asked for, and the Wilson Trustees suggest the foundation of a lectureship on Scottish antiquities and ethnology.

St. Andrews.—The most urgent need is the alteration and extension of the buildings of the United College, which was built between 1827 and 1849, and is now quite antiquated. For this purpose, and for the erection of laboratories in physics and chemistry, £20,000 is required. To put the lectureships in botany, French history, ancient history, political economy, German, geology, and applied mathematics on a permanent basis by raising the salaries to £350, an annual grant of from £2,500 to £2,800 is asked. University extension lectures were at one time given in the neighbouring town, but the scheme failed for want of funds; if, however, the University possessed the necessary resources, matters could be put on a new footing. Additional library accommodation is much required, and a larger annual sum for expenditure on books and scientific journals.

Dundee.—The Trustees are asked solely to give assistance in completing the buildings of the University College. A scheme spread over seven years is suggested, giving the following total capital expenditure:—Medical buildings, £14,000; engineering, physics, and electrical

engineering, £40,800; botany, zoology, geology, £1,500; library, £1,000. An annual sum for maintenance amounting to £2,850, is also asked for.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

THE JUBILEE OF OWENS COLLEGE.—THE ROYAL VISIT.

FIFTY years ago a somewhat obscure, and by no means wealthy, Manchester merchant spent his energies and his fortune in founding a new temple of learning in the Lancashire centre of industry. His devotion to this object has been followed by great results. In the Owens College the people of Lancashire feel that they possess an intellectual centre of their own, suited to their own needs and close to their own door. As a home for their college they have gradually raised a magnificent pile of buildings. Some of these form a noble quadrangle which has just been completed by the erection of the Whitworth Hall, which was on Wednesday last opened by the Prince of Wales. The ceremony honoured by the presence of their Royal Highnesses formed a part of the Jubilee celebration of the College, and was rendered brilliant by the attendance of delegates sent by universities, colleges and learned societies from all parts of the world. Here, and also at the huge social gathering held at the College in the evening, the ladies and the military men had a lower decorative value than usual, for their costumes paled before the masses of scarlet, purple and gold produced by the ample robes of the delegates and the officials of the College.

On Thursday morning a most impressive academic function was held, when the Duke of Devonshire, as President of the College, received from the delegates congratulations on the work of the past fifty years, and good wishes for the future of Owens. Earl Spencer, as Chancellor of the Victoria University, then conferred honorary degrees upon some citizens of Manchester, and upon a large number of the delegates present. The medical men thus honoured were the President of the Royal College of Physicians, the President of the Royal College of Surgeons, Sir Thomas Barlow, Sir John Burdon-Sanderson and Professor Alexander Russell Simpson, who were presented by Professor Young for the honorary degree of Doctor of Science. In the evening the delegates met the teaching staff of the College in the Whitworth Hall, where they dined in a manner befitting the occasion.

The presence of Royalty gave to the celebration the stamp of national importance; but quite apart from this, many facts show that the Owens College is a great institution. It has attracted to its staff many great men, and in turn it has supplied numerous fine teachers to other British and Colonial Universities. Many of its students have attained greatness in careers outside the academic world. The expressions of admiration and regard which have been sent from all the great centres of civilisation prove that the men of academic Manchester, like those of commercial Manchester, are citizens of no mean city. The college lacks the antiquity which some seats of learning boast; but for this reason, it is free from many of the anachronisms to which age is apt to cling. No one, for instance, attends chapel at eight o'clock in the morning within its walls, nor do its authorities consider it essential for students to wear gowns in the neighbouring streets. The College is not richly endowed, but it has been remarked that the endowment of research is apt to degenerate into research for endowment. Brains, labour and capital are doubtless necessary factors in every enterprise. They may, however, be combined in very varying proportions, and where knowledge and industry are to be found, money quickly follows. The future of this provincial college will be great, and its past is well worth study at the present time, for it is the prototype of the numerous similar institutions which are springing up in our cities, and which bid fair to play so important a part in our national life.

Liverpool.

[FROM OUR OWN CORRESPONDENT.]

ROYAL OPENING OF THE DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

THIS hospital, the re-building of which has occupied nearly six years, was formally opened by H.R.H. the Princess Louise on Thursday, the 13th inst. The hospital, as its name perhaps implies, was built by funds left by the late David Lewis, of Liverpool and Manchester. The money was bequeathed in trust to two of Mr. Lewis's nephews, one at present in Australia, and Mr. Ben Levy, of Liverpool, upon whom has devolved the whole of the burden of carrying out what they believed to be the testator's wishes. It is not generally known that there was nothing in the testator's will to prevent the trustees spending the large fortune bequeathed in any manner they wished—on themselves if they desired. The only indication of the will of the testator in the matter was in a letter accompanying the will to the effect that it was the testator's wish that the large amount bequeathed—something like £400,000—should be applied to the benefit of the industrial classes of Liverpool and Manchester. To their great and distinguished honour it can be said that the wish thus informally expressed has been carried out by the two trustees, and one of the objects of the trustees reached its final stage on Thursday last, when the hospital was formally opened by H.R.H. the Princess Louise, who was accompanied by her consort, the Duke of Argyll, and the hospital itself formally transferred from the trustees to the Lord Mayor of Liverpool on behalf of the city.

The hospital is perfect and up to date in all its details, and we are quite sure that as far as the medical and surgical staff are concerned, there will be nothing lacking on their part in order to carry to full competency the object of the testator and his noble-minded trustees.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE SMALL-POX EPIDEMIC.—A SUGGESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The statistics of the small-pox epidemic during the past month show in London alone an average of sixty-four deaths per week, whilst the daily removals to the hospitals have varied between sixty and a hundred. The suffering, the misery, and the loss are, as usual, falling heaviest upon the poor, by far the greater number of cases being notified in Stepney and other East End parishes inhabited almost exclusively by the labouring classes. A vast amount of injury is already being inflicted upon trade; whilst at the West End the influence of the epidemic is being shown in the steady decline in the rents of houses, which, in view of the Coronation season, had advanced to an unprecedented extent. Professional men whose patients come from a distance are beginning to receive intimations that visits from the country will be put off through fear of contagion—a straw sufficiently big to show which way the wind is blowing. In the meantime the efforts to stay the advance of the epidemic, vigorous and extensive as they may be, are quite inadequate to provide in sufficient degree the one prophylactic measure—namely, vaccination and revaccination—by which alone the whole mischief might be put an end to virtually within a month. If contemplation of the preventable death, sorrow, and misery is not enough to stimulate the philanthropist to exertion, one might think that the prospective loss to trade would rouse the commercial classes to recognition of the risk involved. If, as so many authorities believe, the outbreak should continue to extend more widely throughout the metropolis, and to involve more and more, as it has already begun, the districts of greater and suburban London, the effect will be to mar, if not altogether to spoil, the festivities of the Coronation

weeks. Thousands of foreigners and Colonials will be deterred from visiting England, and many more thousands of our own people from visiting town.

That the bulk of the people will accept vaccination if it is brought to their doors, and that even the conscientious objector will yield to a little persuasion in the presence of imminent danger, has been proved by experience in many places, and among others in the Reigate Urban District where I have a residence. The appearance of small-pox at Christmas-time in the village of Meadvale, and the measures taken to prevent its spreading were described by me in your columns at the time. The work of the public vaccinators was supplemented by that of a committee provided with funds by public subscription, and within a few days the entire village was practically protected by vaccination. Similar organisations throughout the metropolis might achieve similar results. The work would, of course, cost many thousands of pounds, but this would be as nothing compared to the burden upon the rates which the extension and prolongation of the epidemic must inflict, not to speak further of the injury to every commercial interest to which I have already sufficiently alluded.

I am, Sir, yours truly,

HENRY SEWILL.

Cavendish Square, March 14th, 1902.

Literature.

THE MEDICAL ANNUAL. (a)

DURING the twenty years that "Wright's Medical Annual" has existed no effort has been spared to make each succeeding volume more worthy of the medical profession and of the brilliant staff of sectional editors that take part in producing this international year-book. Of the thirty-seven contributors seven are Americans, and of the remainder a fair number are provincial men. One and all, however, have attained distinction on the subject on which they contribute. The distinguishing feature of the present volume is the excellent article on X-rays: the apparatus, the value in diagnosis, and their value as a therapeutic agent, from the pen of Dr. John Macintyre, of Glasgow, whose success in the use of the X-ray apparatus has done much to teach the medical profession its great value in diagnosing medical cases, particularly those of the heart and lungs. Of less general interest, but still of great value, is Mr. Abrahams' article on the "Disorders of Metabolism." We have referred particularly to these two contributions as evidence that the reader of the "Annual" is kept informed of the most recent advances in scientific medicine, and we may add that the other contributions are not reprints, but are brought up to the most improved teaching of the day. Nothing stale or unprofitable finds a place in this excellent volume, in which by clearness of statement, aptness of quotation, and helpful and beautifully finished illustrations everything is done to place in the hands of the practitioner a useful, trustworthy guide to modern medical practice.

GILES ON MENSTRUATION. (b)

THIS monograph, belonging to the *Medical Monograph Series*, treats succinctly and clearly of "Menstruation and its Disorders," and will unquestionably be useful as a standard work of reference to the medical student and practitioner, especially as no other work on this particular subject has been published for many years, and in this the author has practically exhausted the subject, the importance of which, as a guide to the "physiology of gynecology," is obvious. The book abounds with useful practical remarks such as the following: "Pain before the period is generally sacral, being due to uterine congestion, probably associated with and aggravated by tonic contraction of its lower

(a) "The Medical Journal: A Year-Book of Treatment and Practitioners' Index." 1902. Twentieth Year. Bristol: John Wright & Co.

(b) "Menstruation and its Disorders." By Arthur E. Giles, M.D., M.R.C.P. Lond., F.R.C.S. London: Baillière, Tindall, and Cox. 1902. Pp. 110. Price 2s. 6d., net.

pole, the region of the cervix and the os internum; whilst, during the period, the pain is generally hypogastric, being principally due to painful uterine contractions, &c." The significance of pain associated with the menstrual periods is a point to which the author has devoted great attention, and practitioners will appreciate the value of the hints which he gives. The chapters on menorrhagia, metrorrhagia, and dysmenorrhœa are particularly useful, if only to insist on a vaginal examination when these symptoms are present, and also as showing the great alleviation which can be afforded to patients by proper treatment, hygienic, medicinal and surgical, in the use of appropriate pessaries, curetting, &c., or the major operations, if malignant disease be diagnosed. This work will certainly add to the reputation of what promises to be a very serviceable and practical series of monographs.

UGLY, A HOSPITAL DOG. (a)

THE author certainly possesses a special talent in the matter of sentimental little stories illustrative of hospital experiences, seen from the in-patient's point of view. Although he writes in a simple, unpretending style, he evidently addresses himself to a public other than mere "small fry," indeed many of his smartest allusions would be unintelligible to those still at the threshold of life's experience. The principal story, that of "Ugly," is prettily related, and brings in a host of incidents which cannot fail to stir the feelings of the reader. The annals of hospital life indeed are rich in "incidents," and in the hands of Dr. Dabbs they are divested of their sordid and repulsive attributes, and serve sometimes to point a moral, sometimes to adorn the tale. Dr. Dabbs is seen at his best in prose. Of his attempts at versification perhaps the less said the better. The volume is tastefully bound, and admirably printed, and how it can be sold at the price is a mystery which we are unable to solve.

HISTORY OF THE SOCIETY OF APOTHECARIES.

THIS little book by Mr. Percy G. Lodge, F.R.C.S., L.S.A., which was published a few days ago by Messrs. J. and A. Churchill, is withdrawn for the present from circulation, in order to be recast and certain necessary corrections made.

Obituary.

SIR WILLIAM GUYER HUNTER, K.C.M.G., M.D.

WE regret to announce the death of Surgeon-General Sir William Guyer Hunter, K.C.M.G., which took place suddenly on Friday last. He was born in 1831, and graduated M.D. at Aberdeen in 1867. In 1852-53 he served in the Burmese campaign, and subsequently became Principal and Professor of Medicine in Grant Medical College, and in 1880 was made honorary surgeon to Queen Victoria and Vice-Chancellor of Bombay University. He was created a K.C.M.G. in recognition of his services during the outbreak of cholera in Egypt in 1883. From 1885 to 1892 he represented Central Hackney in Parliament, and was a member of the London School Board from 1886 to 1888. Sir Guyer Hunter was honorary surgeon to the King, consulting physician to Charing Cross Hospital, Fellow of many of the learned societies, colonel commandant of the Volunteer Medical Staff Corps, and a Knight of Grace of St. John of Jerusalem.

Novelties.

LESLIE'S WASHABLE CREPE BANDAGES.

WE have received specimens of an improved crepe bandage from Messrs. Leslie, Limited, of London. This bandage possesses a really remarkable degree of elasticity which enables it to adapt itself to any part of the

body without creasing, the pressure exerted thereby being uniform throughout. Another great advantage of this sort of bandage is its extremely porous nature, which allows free means of air to the skin. There is a woven edge which presents unravelling, without reducing the resiliency of the material. Not the least important of its qualities is the fact that it can be repeatedly washed without impairment of its special attributes. For bandaging the head and neck, and to exert pressure on varicose veins, &c., this material is vastly preferable to any other with which we are acquainted.

ROWNTREE'S COCOA AND CHOCOLATE.

It has been remarked that many manufacturers after they have made a name become less careful in the superintendence of their goods, which thereupon gradually deteriorate and others come in and take their place. This cannot be said of the "Elect" Cocoa and "Milk Chocolate" now under inspection. Some years ago, when analysing the cocoas of commerce we put those from Messrs. Rowntree's establishment under analytical survey, and found them to completely answer the tests for purity and careful manufacture. Recently the same firm has introduced some improved milk chocolate, and whilst examining this we also took occasion to test the cocoa previously analysed years ago by us, and are glad to report that both are absolutely trustworthy, and that invalids as well as those in health may have confidence when consuming them that they are what they are represented to be.

THE "M.P." PIPE.

THE "M.P." Pipe Co., 29, Ludgate Hill, have submitted to us a pipe which represents another attempt to solve the smokers' problem, viz., a pipe which shall not become foul. In the "M.P." pipe the vulcanite mouthpiece is split longitudinally, the two halves hinging on a pin near the lip end. The parts are in close apposition, and there is no danger of leakage from the surfaces in apposition. In proceeding to clean the pipe one has only to withdraw the mouthpiece, open and wipe it, whereupon it is as good as new. As it fits into the pipe proper close up to the bowl, no cavity is left where pyrolygneous filth can collect. On the whole the pipe appears to realise to a great extent the desideratum. Personal experience thereof has proved perfectly satisfactory.

NATIONAL HOSPITAL FOR CONSUMPTION.

THE tenth annual meeting of the friends and supporters of the National Hospital for Consumption for Ireland, was held in the Royal College of Physicians, Kidare Street, on Friday last.

The annual report of the Hospital was read, and the Medical report. The latter stated that during the past year 164 patients have been under treatment. Of these 123 have been discharged and two died, leaving thirty-nine still in the Hospital. Ninety-one per cent. gained weight, and 80 per cent. were obviously improved. From what we know of the after history of some of our patients who were in the Hospital four or five years ago, we feel that there is an increasing probability that in some of these cases the disease has been permanently arrested, and that to many of the remaining cases some years of working life have been added. The number of discharged patients is the same as in the previous year. They have, however, been kept two weeks longer in hospital, the average stay

(a) "Ugly, a Hospital Dog," Told by Himself, with Recitations and Readings. By George H. R. Dabbs, M.D. Price 1s. London: Charles William Deacon. 1901.

having been 13-4-5 week—a period not exceeded since 1897, when the time was 15½ weeks. Eight additional beds were provided last July, so that during the latter half of the year forty beds have been available for patients. But the demand for accommodation has been greater than ever. Frequently during the last year the number of applicants waiting for admission has been nearly 100, and on the men's side a delay of about four months has been quite unavoidable. In too many cases when the vacancy does occur, the applicant replies that he is "now too ill," and a still larger number are found on examination to be medically unsuitable. We hope that with the additional accommodation provided by the new building now ready for patients we may be able to admit applicants more promptly, and to treat them in an earlier stage of the disease. It is satisfactory to note that most of the patients endeavour after their discharge to keep up, as far as their circumstances admit, the treatment and mode of life with which their stay in the hospital has made them familiar, and that the measures necessary to guard against infection are more generally understood and appreciated than they were a few years ago.

His Excellency the Lord-Lieutenant, who had honoured the meeting by his presence, proposed the adoption of the report. This was seconded by the President of the Royal College of Physicians, and adopted unanimously. After the transaction of some further business the meeting adjourned.

Dublin Death Rate for the Year 1901.

ACCORDING to the yearly summary of the weekly returns of births and deaths in Dublin for the year 1901, just issued by the Registrar, the number of deaths registered during the year was 9,751, equal to 25·4 in every 1,000 of the population. The rates for the several Registrars' districts range from 11·2, the rate for Crumlin, to 31·7, the rate for the Castle Street District. Diseases of the respiratory organs caused 1,860 deaths, diseases of the circulatory system caused 876 deaths, and phthisis caused 1,274 deaths. There were 499 uncertified deaths, there having been no medical attendant during the last illness; of these, 325 were deaths of infants; 512 infants under one month old died during the year, and of these 157, 30·7 in every 100, were uncertified, no medical attendant having been in attendance; 29 per cent. of all ages were those of infants. From Table V. we learn that the deaths in families of the "professional and independent class" were equal to a death-rate of 29·6 a 1,000 of persons in that class; in the "middle class" the death-rate was 18·5 a 1,000; among the "artisan class and petty shopkeepers" it was 22·1; and in the "general service class" and "inmates of workhouses" combined, it was 35·9 a 1,000 of persons in that class.

A Sad End.

An inquest was held at Edmonton last week on the body of Herbert Blackburn, L.R.C.P., L.R.C.S., who committed suicide at an Inebriates' Home.

Medical, Sickness and Accident Society.

THE monthly meeting of the Executive Committee of the Medical, Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on 28th ult. There were present the Chairman (Dr. de Havilland Hall), Dr. J. B. Ball, Dr. Walter Smith, Dr. F. N. Mutch, Dr. M. Greenwood, Mr. F. S. Edwards, Dr. Fredk. S. Palmer, Dr. St. Clair B. Shadwell, and Dr. W. Knowsley Sibley. The committee examined a long list of claims, of which about a score are cases of permanent incapacity. Of the remainder a large proportion arose from bronchial affections, which at this season are very prevalent. A considerable number of claims are on the list caused by influenza, but there seems reason to hope that the epidemic will not be so severe as on previous occasions. Very few claims from this cause have been received by the society in the last few days. A satisfactory addition to the new membership was reported, and a considerable number of the existing members have availed themselves of a somewhat recent alteration of the rules enabling any member of

five years' standing to apply to have his sick benefit increased to £6 6s. per week. Prospectus and all information on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Ex-President Kruger's Physician.

DR. SCHOLTZ, who has just died, was formerly physician to Mr. Kruger. He accompanied Lord Roberts into Pretoria.

Westminster Hospital.

UNDER the patronage of the Queen and the Princess of Wales a grand concert was given at the Empress Rooms, Kensington, on Tuesday afternoon, in aid of the funds of this, the oldest London hospital supported by voluntary contributions. The object of the concert was to assist in raising a sum of £25,000, which is still required to meet the expenses incurred in carrying out very extensive improvements and bringing the hospital up to date, and also to enable the work of the hospital to be successfully carried on. In moving a hearty vote of thanks to the artists who had kindly given their services for the benefit of the hospital, Mr. George Cowell, one of the vice-presidents, made the announcement that, together with donations sent by those who could not attend, the concert had realised so far the substantial sum of £270. After deducting expenses, about £240 would be handed over to the hospital. This, he thought, was very satisfactory, and he thanked all who had assisted to bring about such a result. Among those who contributed to the programme were Mme. Belle Cole, Mme. Ruth Lamb, Miss Beatrice McEntire, Signor A. Batti, Mr. Hayden Coffin, Mr. Mervyn Dene, and Mr. Charles Capper.

Cholera among Pilgrims.

PRIVATE telegrams from Egyptian pilgrims to Mecca state that cholera is assuming alarming proportions. Practically the whole route of the pilgrimage is affected, from Djeddah to Medina and Mecca. The Egyptian Government is taking stringent precautions to prevent the malady being introduced into Egypt.

British Laryngological Association.

A VERY successful dinner was held by the British Laryngological, Rhinological, and Otological Association on March 14th at the Café Royal. The President of the Society, Dr. John MacIntyre, occupied the chair. There was a good gathering of London members, and among those from provincial centres were Messrs. Bark, of Liverpool, Lamb, of Birmingham, Woods, of Dublin, O'Callaghan, Stokes, and Sir William Dunn, M.P. After the usual loyal toasts, the "British Laryngological, Rhinological, and Otological Association" was proposed by Dr. Hawthorne and responded to by Mr. Lennox Browne, who spoke highly of the contributions of Irish laryngologists. The toast of "The Guests," proposed by the President, was replied to by Sir William Dunn, M.P., who humorously declared his inability to pronounce the name of the society at that period of the evening or indeed at any other time. Mr. Mayo Collier, in proposing the health of "The President," eulogised the energies and enthusiasm of Dr. MacIntyre in the advancement of their knowledge of the uses of electricity and the Röntgen rays in throat work. A good programme of music was provided by Mr. Wilhelm Ganz, assisted by Señor Guetary and Mr. Mervyn Dene. Mr. Woods and Dr. Daniels also assisted.

Royal Dental Hospital of London.

AT the annual general meeting of governors held at the new hospital in Leicester Square, on Thursday last, Mr. John Hampton Hale, vice-president, in the chair, the report stated that the new buildings were now complete in every detail, and during the past nine months had been open for the reception of patients. During the year 70,040 cases had been treated, an increase of 864 over the total of the previous year, and 50,785 more than the number treated in 1874 (the first year of the hospital's existence). The committee were gratified to be able to notify a small increase in the income. Unfortunately the income was found to be insufficient, and the committee earnestly appealed for increased help to meet the additional expense entailed by the enlarged buildings.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DR. TATE.—You should either re-vaccinate the girl and then certify the vaccination or else write to the Local Government Board for directions. In no case can you or ought you to certify a vaccination performed by any one other than a registered medical practitioner. Further, in no case should vaccination or re-vaccination be done from material taken from a case of re-vaccination. The fact that such had been done in this case, would we think, render vaccination with proper material necessary.

MR. C. E. S.—We have posted the letter to "The Home Secretary" and are of opinion that having done so, much, no further trouble should be taken in the case.

MEDICAL ADVICE AT THE EXPENSE OF THE PROFESSION.

A few weeks since a Glasgow labourer who died suddenly in a dispensary which he had entered to obtain free medical attendance at the cost of the Parish, was found in possession of two savings bank books, which showed that he was a capitalist to the extent of over £500. A Perth man also died last week leaving a fortune of £1,400 who had been an inmate of the local poorhouse for nearly six months. These are specimens of every day cases in which the medical profession is robbed and the ratepayers imposed on.

A. B. writes:—"Can you recommend any publication which contains a list of sanatoria for the open air treatment of phthisis?"

[* The best publication for our correspondent's purpose is *The British Sanatoria Annual* the new edition of which for 1902 has just appeared, published by Messrs. John Bale, Sons and Danielsson, Ltd.—Ed.]

CADAVERS SAVED FROM FIRE.

During a fire in a hospital attached to a medical school in Chicago recently, the firemen, who groped their way through the dense smoke, heroically carried out six dead bodies. The bodies had just been received for dissection, and were lying partly clothed, on the floor, and the firemen thought they were patients or attendants who had been asphyxiated by the smoke and gas. (*New York Medical Record*.)

MR. M. SMITH.—We regret that we are unable to avail ourselves of the MS. you have left with us, as we had previously made other arrangements.

EARLY VACCINATION AND EARLY OPPOSITION TO VACCINATION.

A CORRESPONDENT sends us the following extract from Bettany's "Eminent Doctors," thinking it will be read with interest at the present time:—"In the early days of vaccination (November, 1895) Miss Bayley, of Hope, near Manchester, had vaccinated 3,600 persons, and a female friend of hers 2,000. Miss Bayley commenced by offering a reward of five shillings to anyone who could produce an instance of the occurrence of small-pox in any person vaccinated by her. Out of the whole number of cases above mentioned, however, only one claim was made; and Miss Bayley found, on referring to her books, that a mark had been made against the name, indicating a suspicion that the vaccination had not been effective.

"A small village in Gloucestershire stood out most resolutely against vaccination. At last deaths from small-pox in this village assumed such alarming proportions and swelled so enormously the cost to the parish for coffins and burials, that the officials were moved to urge the people authoritatively to be vaccinated and so save the parish expenses."

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, MARCH 19th.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—8 p.m. Mr. Chichele Nourse: Cases illustrating the Correlation of Diseases of the Throat, the Nose, and the Ear.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (30, Hanover Square, W.).—8.30 p.m.—Dr. Hamilton Cumming (Torquay) will introduce a Discussion on Chronic Affections of the Kidney and Merid Conditions of the Urine arising therefrom, in relation to Balneological, Climatic and Dietetic Treatment.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. C. Stewart: Lecture on the Organs of Respiration.

THURSDAY, MARCH 20th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m.—Clinical Cases will be shown by Mr. Watson Cheyne, Mr. Jackson Clarke, Dr. Atwood Thorne, Dr. Risien Russell, Dr. L. Guthrie, Mr. E. Boughton, and others.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m. Dr. F. T. Roberts: On the Comprehensive Study of Thoracic Phthisis, Lumlilan Lecture III.

FRIDAY, MARCH 21st.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. C. Stewart: Lecture on the Organs of Respiration.

EPIDEMIOLOGICAL SOCIETY (11, Chandos Street, Cavendish Square, W.).—8.30 p.m.—Dr. Daniels: Infantile Mortality in the Tropics.

DUBLIN.

THURSDAY, MARCH 20th.

DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION (Front Hall, Trinity College).—8.15 p.m.

ROYAL COLLEGE OF SURGEONS.—Council Meeting.

FRIDAY, MARCH 21st.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Pathology, Royal College of Surgeons, 8.30 p.m.

TUESDAY, MARCH 25th.

Conjoint Examinations.—Preliminary commences.

Appointments.

BRECHING, D. H., B.A. Syd. Univ., M.R.C. M. Edin., Medical Officer to the Post-office at Huddersfield.

DICK, GEORGE, M.B., Ch.B. Edin., Medical Officer of Health for Caithness-shire, Royal Burgh of Wick, and Thurso Burgh.

MARTIN, JOHN MIDDLETON, B.A., M.B., B.C., D.P.H., Cantab., Medical Officer of Health for the Stroud Urban District Council.

MCAUGHTON, J. G., M.D., M.R.C.P. Edin., Honorary Medical Officer, Chorlton-upon-Medlock Dispensary, Manchester.

MORISON, R., M.B., Ch.B., Junior House Surgeon to the Birkenhead Borough Hospital.

WHITE, G. F., M.D., Senior House Surgeon to the Birkenhead Borough Hospital.

Vacancies.

Bradford Poor-law Union.—First Resident Assistant Medical Officer for the Hospital and Workhouse of the above Union. Salary £125, with prescribed rations, apartments, and washing. Applications to Thos. Crowther, Poor-law Officer, 22, Manor Row, Bradford.

Carlton Union.—Fever Hospital Nurse. Salary £30 per annum, with rations and apartments. Applications to John George Glover, Clerk. (See Advt.)

Chesterfield and North Derbyshire Hospital and Dispensary.—Resident House Surgeon. Salary £120 per year, with board, apartments, and laundress. Applications to the Secretary at the Hospital.

Co. Mayo.—Qualified Medical Assistant. Applications to Dr. Cram, Ballyhaunis, Co. Mayo. (See Advt.)

Down County Infirmary.—House Surgeon. Salary £20 per annum, with board and residence. Applications to Dr. Tate, Downpatrick. (See Advt.)

Essex and Colchester General Hospital.—House Surgeon. Salary £100 a year, with board, washing, and residence in the Hospital. Applications to C. L. Becher, Secretary.

Galway Hospital.—Resident Medical Officer and Compounder of Medicine. Salary £75 per annum, with rations and apartments. Applications to S. J. Leonard, Clerk. (See Advt.)

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary commences at £150 per annum, with furnished apartments, board, attendance, and washing. Applications immediately to the Medical Superintendent.

London County Asylum, Bexley.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Immediate applications to E. W. Partridge, Esq. (See Advt.)

Newcastle-upon-Tyne Dispensary.—Visiting Medical Assistant. Salary £160. Immediate applications to the Honorary Secretary, Joseph Carr, 41, Mosley Street, Newcastle-upon-Tyne.

Royal University of Ireland.—Examiners in Surgery, Midwifery, Pathology, and Ophthalmology. Applications to the Secretaries not later than April 19th. (See Advt.)

Births.

GILLIARD.—On March 13th, at St. Margaret's, Purley, the wife of E. Gilliard, M.R.C.S., L.R.C.P. Lond., of a son.

PHILLIPS.—On March 16th, at 88, The Avenue, Ealing, W., the wife of George Phillips of a son.

REARDON.—On February 23rd, at Bruff, the wife of D. F. B. Reardon, L.R.C.S.I., L.R.C.P.I., of a daughter.

THOMSON.—On the 10th inst., at Bridge House, Retford, Notts, the wife of Dr. George Thomson, of a son.

WEBSTER.—On March 11th, at 47, Craven Park Road, Harlesden, N.W., the wife of Dr. A. Irby Webster, of a daughter.

WILLIAMS.—On March 13th, at Much Hadham, Herts, the wife of Dr. W. Blundell Williams, of twin daughters.

Marriage.

LONGHURST-PHILLIPSON.—On March 8th, at St. Alban's Church, Teddington, Percy A. Longhurst, M.R.C.S., L.R.C.P. Lond., to Naida Eveleigh Phillipson, eldest daughter of the late N. E. Phillipson.

Deaths.

HETLEY.—On March 13th, at Norbury Lodge, Upper Norwood, Frederick Hetley, M.D., J.F., D.L., in his 81st year.

JOHNSTONE.—On March 16th, at St. Moritz House, Brighton, Athol A. W. Johnstone, F.R.C.S., aged 81 years.

MANSON.—On March 1th, at Christmas Island, from a gun accident, Patrick T. Manson, M.B., Lond., aged 24, eldest son of Dr. Patrick Manson, C.M.G., F.R.S.

PRESTON.—On March 16th, at 4, Abercorn Place, N.W., Wm. John Preston, M.D., aged 82 years.

TURNBULL.—On March 7th, at Cleveland Gardens, Surgeon-Major Francis Turnbull, I.M.S. (retired), aged 82.

ON THE USE OF X-RAYS IN MEDICAL DIAGNOSIS. (a)

By WILLIAM S. HAUGHTON, M.D.,

Surgeon to Steeven's Hospital; University Demonstrator in Röntgen Photography; Member Röntgen Society of London.

DURING the past six years the X-ray examination of a considerable number of patients (some 1,900 odd) in hospital and private practice has brought home to me the conviction that while surgery and dentistry have claimed an ever-increasing amount of help from the rays, medicine, at any rate in this country, has not availed itself as fully as it might have done, of this additional mode of diagnosis.

The reason for this may be twofold—a natural diffidence to adopt a new method of examination whose utility was unproved, or neglect on the part of advocates in the process to call attention to its utility of medicine.

The first of these difficulties is now removed by the records of splendid and sterling work from French, German and American centres, and with regard to the second I may state that some three years ago I had the honour of calling attention to its possible value in the Pathological Section of the Academy, and in a Presidential address before the Dublin University Biological Association. It is my object briefly to call attention to those applications in medicine which have been proved successful, only detailing one or two illustrative cases among those which have come under my own notice.

In pulmonary tuberculosis I need hardly call attention to the great value of an early diagnosis, placing, as it does, the physician in a much better position to prescribe treatment, and greatly increasing the patient's chances of recovery.

In this disease, whose great prevalence and high mortality are universally recognised, X-rays have rendered splendid service, and will, I am confident, come into very general use when their true value is justly estimated.

Two constant physical signs are present, in this affection, when examined by the Röntgen method, namely, *opacity*, which depends on the *extent and density of consolidation* in the lung; and restricted movement of the diaphragm on the affected side, depending on the *loss of elasticity* in the lung-tissue.

Before detailing cases, let me describe my method of conducting this examination.

I may say at the start that the fluorescent screen is infinitely preferable to any photographic method for these reasons: The cardiac movements disturb the lung tissue for a considerable area around, and though very short exposures may avoid the faults

due to respiratory movements, the disturbances due to the heart considerably lessen the value of the examination. On the other hand, the method by screen examination occupies a much shorter time—a few seconds in some cases—and possesses the further advantage that with the eye one can actually *watch* the movements of the heart and diaphragm as their contour and position change, and record them on a suitable surface from which accurate measurements can be made.

I find most X-ray workers of experience agree with me in this opinion, and when *very delicate differences* in shadow have to be estimated, as happens in very early cases of lung trouble, one can so graduate the X-ray light, while watching it on the screen, as to indicate a very slight opacity, which cannot be done in the photographic method.

To examine a chest, one merely places the patient with his back to the Röntgen lamp, which is placed at a fixed, known distance from the screen, and in a fixed relation to the anatomical structures in the thorax.

I find two feet from the lamp to screen a convenient working distance, at the level of the ensiform cartilage for observing the movements of heart and diaphragm.

It must here be pointed out that if the comparison between two different patients is to be of any use, the successive examination must be conducted on what is known in experimental science as exactly similar conditions. Hence the necessity for adopting some such constant method as I have described.

If the patient is more comfortable sitting down the examination can be made so—but diaphragmatic movements are thus impeded. While if the recumbent position is essential for the safety of the case, a canvas stretcher permits the examination in the horizontal position.

Having placed patient in one of these positions, a large screen is placed over chest, the light turned on, and observations are made of the position of the heart, and excursions of the diaphragm in quiet breathing. Then its level in forced inspiration and expiration are observed, and finally a close scrutiny is made of the relative transparency of the two lungs. And any isolated shadows due to patches of consolidation are searched for. During the course of this examination it is very necessary to vary the amount and quality of X-ray light, as I find slight differences of shadow may be overlooked in a light which is too strong.

To record the results of this examination I use one of two graphic methods. First, looking at shadow of heart and diaphragm on screen, with a dermatographic pencil I trace the outline of each on the patient's skin, first in full inspiration, then in full expiration. Next, the position of any shadow due to consolidation is marked on skin. From these marks on skin a tracing is made on tracing paper (some of

(a) Paper read before Medical Section, Royal Academy of Medicine of Ireland, March 7th, 1902.

which were exhibited), noting position of supra-sternal notch, ensiform cartilage and nipples, or any special rib.

The other method of recording is to use a large sheet of celluloid, placed either on patient's skin or in front of screen, and on this celluloid the shadows are traced, precisely as in the first method.

One advantage of the celluloid method is that a case can be examined and recorded without the removal of clothes, a point that is sometimes much appreciated by the patient.

X-ray examinations in the following varieties of pulmonary tuberculosis have proved most valuable:—

In the diagnosis of very early disease, where there are no physical signs or where they are very doubtful, for instance, in a patient suffering from anæmia, digestive troubles, and a slight temperature, but with no cough or expectoration.

Next in one with very slight physical signs; or in one with complications such as bronchitis, pleurisy, emphysema, or pneumonia, masking the tuberculosis.

Again to confirm diagnosis, or to test lungs, when a known tuberculous focus exists elsewhere; or in cases with a bad family history, to allay fears on part of patient, or relations.

DIAGRAM 1.

In a very early case of consumption the following signs are found present in an X-ray examination.

1. Slight opacity of one apex, or of that part of lung where disease is commencing. As I have pointed out elsewhere, to detect this slight opacity due to consolidation requires sometimes a very considerable experience in X-ray screen examinations, and manipulative skill in adjusting the quality and quantity of the X-ray light.

2. Restricted movement of diaphragm in the affected side, due to loss of elasticity in the lung tissue. This restriction of movement is most marked, as a rule, in the lower ranges.

3. In some cases, during deep inspiration, the heart is displaced towards affected side.

Later on in such a case where the usual physical signs have become established, X-rays show an increase in the opacity and size of the shadow of the consolidated patch, and at the same time the diaphragm's movements become more restricted on the affected side.

Very often in a case where one apex only is suspected, X-rays will demonstrate a patch of consolidation in the other apex.

We can easily see the important bearing of these observations on the treatment of a case of phthisis, especially when taken in conjunction with percussion and auscultation. The results of the usual methods of examination can be confirmed, and in some cases the presence of more extensive disease diagnosed. In the course of treatment the precise extent and

progress of the disease may be watched by X-ray examinations repeated at regular intervals.

DIAGRAM 2.—PHTHISIS.

The process of resolution in a patch of consolidation is marked by a diminution in the opacity and size of its X-ray shadow.

What has been said of the value of this examination in the treatment of a case is, of course, equally important in giving a prognosis.

When phthisis is complicated by bronchitis the former condition is recognised by the patches of opacity.

When pleurisy is present it can be distinguished by signs to be mentioned later on. This is true also of such complications as emphysema and pneumonia.

In the diagnosis of acute pneumonia little doubt exists as a rule, but where the disease commences in the central portion of a lobe much doubt may exist for a time.

The Röntgen method in pneumonia yields following signs:—

1. Dense opacity of part or whole of lobe, according to degree of affection.
2. Restriction of diaphragm on affected side or sides.
3. Displacement of heart away from affected side, accompanied by dilation.

DIAGRAM 3.—PNEUMONIA.

In the after-treatment of a case of pneumonia, and more especially in forming a prognosis as to risks of secondary affections of the lung, I believe X-rays will be of the greatest service.

For a considerable time after the crisis in pneumonia, some weeks, the affected lobe is found to be somewhat opaque, and the diaphragm's movements much impeded by the want of elasticity in the lung. If these signs (when other physical signs are absent) persist for a considerable time, as they sometimes do, the after-treatment of such a case would be necessarily more cautious and prolonged.

The complication of pleurisy in pneumonia, also leaves behind it signs of restricted movement.

DIAGRAM 4.—LOBULAR PNEUMONIA.

DIAGRAM 5.—IN PLEURISY.

When an effusion is present the screen shows following signs:—

1. Contour of diaphragm is partly or wholly obscured, the pleuritic fluid being very opaque compared with lungs.
2. The lung on affected side is more opaque uniformly, due to compression by the effusion.
3. The heart-shadow is also of course displaced away from the fluid.

When the fluid is free in the pleural cavity, changes in the patient's position will cause a corresponding change in the appearance on screen; while in an encysted pleurisy the shadow is stationary.

X-rays also show much more displacement of the heart than can be elicited by percussion, in a certain number of cases.

Interlobular effusion can also be readily distinguished.

In emphysema of the lungs the screen shows a much brighter and more transparent condition, due to dilatation of air vesicles and greater quantity of contained air. This is of course present on both sides.

In pneumo-thorax, both with or without hydro-py- or hæmo-thorax, the pleural space filled with air is remarkably transparent when contrasted with opposite side of chest.

Tumours of Intra-Thoracic Origin.—Malignant growths in lung, pleura, or mediastinal glands; also bronchial tuberculous glands, and some cases of oesophageal cancer, all yield distinctive X-ray signs.

Aneurysm of Aorta.—This condition is very readily diagnosed by X-rays, and especially in early stages seems of larger area than percussion can indicate.

Normal Heart.—Its size, shape, and character of pulsation (i.e., its size and position in systole and astole) can be watched and measured on the screen.

In many forms of cardiac disease most valuable information is obtained by observing changes in the size, shape, position, and pulsation of the heart. For instance, dilatation of an auricle can be distinguished from that of a ventricle. It is superfluous to indicate the value of these observations during the treatment of cardiac disease.

DIAGRAM 6.—ANEURYSM.

DIAGRAM 7.—NORMAL HEART.

In the abdomen we can now measure accurately the size, position, and shape of a distended stomach by giving a large dose of subnitrate of bismuth and observing the shadow cast by the stomach fifteen or twenty minutes after.

I should also mention that dilatation of the oesophagus due to stricture can at certain levels be diagnosed by the same means.

In summing up the uses of X-rays in medical diagnosis I would most vigorously insist that this graphic method for observing and recording the thoracic or abdominal organs by the eye should only be used as an aid to, and in conjunction with, the tactile and auditory senses of percussion and auscultation.

Before and after the meeting Dr. Haughton demonstrated this method of screen examination with his apparatus on a number of patients suffering from phthisis (early and late), malignant tumour of oesophagus, and pleurisy.

Deaths under Chloroform.

A DEATH under chloroform occurred a few days since at the Oswestry Cottage Hospital, the victim being a man, age 50. No details were given concerning the mode of administration, and the usual verdict was returned. An inquest was held by the Coroner for St. Pancras on the 16th inst., on a man, age 41, who died under chloroform (A C E mixture) given on a mask at the Royal Free Hospital during an operation for the relief of an abscess in the neck.

TREATMENT OF TUBERCULOSIS BY SPECTRAL ANALYTICAL BLUE LIGHT.

By Drs. STERKEL and GUSTAV KAISER,
Of Vienna.

[AS DEMONSTRATED IN PROF. EXNER'S LABORATORY.]

THERE is already a fairly abundant literature giving the history of the adoption of blue rays by Ernest Sterkel and applied clinically with much success by Gustav Kaiser.

Sterkel is the manager of the "Wiener Filiale" Company, owned by the firm of Reiniger, Gebbert, and Schall, manufacturers of electro-medical apparatus, who seem to have given a good deal of time and attention to static electricity, or Frank-linisation, as applied to medicine. The previous literature of the subject is very poor, and the best he could discover was the "Etudes sur l'Electricité," by Beckenstein (published by J. B. Baillière, Paris), which contains all that is known on the subject. The electrodes were of gold, silver, iron, antimony, zinc, &c., one globular, the other pointed for spark, while the patient was seated on an insulated chair, to which one pole could be attached at will. To observe the effects of these metals on the body the electrodes had to be made broad, while small points were made for observation under the microscope. With this arrangement the small points gave the following colours:—Aluminum, blue; antimony, white; lead, violet and light green; cadmium, green; iron, light blue; gold, reddish brown; cobalt, light blue; copper, green; platinum, white; silver, light green; bismuth, greenish blue; zinc, sky blue; tin, light yellow.

These different metals varied in their therapeutical effects, but a peculiarity arose when blue glass was put on the green rays of the copper electrode, the resulting colour being blue. Then followed spectral analysis, and out of ten different shades of blue only one retained the colour.

According to the papers read before the Electro-technic Society and at the Medical Institute, Sterkel and Kaiser began to operate conjointly on bacteria. Pure cultures of tubercle bacilli under a 32 candle-power incandescent lamp were destroyed in a short time. Sterkel next devised a concentrating reflector for penetrating the body and acting on the bacilli in the internal organs. Kaiser conducted his experiments in Prof. Exner's laboratory. The reflector raised the point or focus to 3,000 candle-power.

1. He prepared three pure cultures of tuberculous bacilli for the usual electric light and three for his "spectral analytical blue" light. The cultures were placed at five metres for thirty minutes under the different lights on six different days.

The three cultures under the blue light contained only dead bacilli while those under the ordinary light were still active. Animals were injected with the resulting media in both experiments—that subjected to the blue light giving negative, and the arc light positive results.

2. Cultures were prepared in a similar manner and placed for the same period of time at the back of patients, while the blue rays passed through the patient on to the cultures. On examination after three hours the bacilli were found to be much enfeebled.

3. The blue light rays again (with three cultures) were passed through a hollow lens filled with ammonia, alum, methylene blue, by means of the reflector and killed the bacilli in a very short time—animal experiment proving negative.

This hollow lens is made with two watch glasses

sealed together with a rubber band to which are attached two tubes for ingress and egress of solution at freezing temperature.

4. Light from the reflector was passed through two convex lenses and a bi-sulphide of carbon prism. Cultures were placed in the red, yellow, blue and violet—ultra-violet portions of the rays.

On examination the organisms exposed to red and yellow rays were still alive, but those under the violet-ultra-violet and blue were quite inert, as proved from animal injections.

5. A photographic negative with a thin film was placed at the back of a patient and the light passed through the body a distance of five metres, and in twenty-five minutes the bacilli were almost lifeless.

Kaiser next commenced operations on tuberculous patients. After six weeks treatment with six sittings daily the night sweats and bacilli in the sputum disappeared notwithstanding bad weather and indifferent circumstances.

In a second patient who had a tuberculous ulcer on the leg, this healed within four weeks.

An eczema of six months standing was healed within five weeks.

These results confirm the theoretical assumption that the blue to the ultra-violet rays are bactericidal; that the heat of the rays can be abrogated; that the intensity of the light is in proportion to the distance; that the blue rays are a powerful absorbent; and that they are also anæsthetic.

The patients experimented on were poor out-door patients or in workhouses with no resources. The use of "Tropon" artificial food for adults, and "Hygama" for children was prescribed.

ON STONE IN THE FEMALE BLADDER. (a)

By P. J. FREYER, M.A., M.D., M.Ch.,

Surgeon to St. Peter's Hospital, Lieut.-Colonel I.M.S. (Retired).

MR. PRESIDENT AND GENTLEMEN,—I have in the first place to thank you for the compliment you have paid me in inviting me, who have not the honour of being a Fellow of your Society, to be present this evening to contribute a short communication on "Stone in the Female Bladder" to its proceedings.

I propose giving you brief details of an interesting case sent me by Dr. H. Macnaughton-Jones, your former President, and, taking this case as a text, making some general observations on my personal experience of stone in the female bladder.

An unmarried woman, æt. 24, was sent to me in April, 1901, by Dr. Macnaughton-Jones with a diagnosis of stone in the bladder and vesico-vaginal fistula. For about a year previously she had suffered from increased frequency of micturition, pain in passing urine, and hæmaturia. Latterly, her symptoms had become much aggravated, and on admission to St. Peter's Hospital she was in a very miserable condition, being unable to retain her water for more than a quarter to half an hour, the pain and scalding being intense, and the urine thick, ammoniacal, and extremely offensive. The vulva was swollen and raw from the constant passage of foul urine over the parts, as well as from leakage through a vesico-vaginal fistula.

On April 24th, the patient being anæsthetised I performed litholapaxy. When the lithotrite was first introduced I failed to grasp the stone between the blades, though it was felt grating against the instrument. This was due to the shape of the stone, and its being fixed between the bladder walls, which felt contracted on it. I then distended the bladder with boracic lotion and re-introduced the lithotrite, when the stone was at once caught by its long axis, but, being about three inches long, the instru-

(a) Read at meeting of British Gynecological Society, March 13th, 1902.

ment failed to look on it. The calculus was released and caught by its short axis, when it was rapidly crushed into fine *débris*, and evacuated by the aspirator through a No. 18 cannula, English scale. A large quantity of stinking muco-pus was also washed out. The *débris* when dried weighed 237 grains, and on examination it was found to be composed mainly of soft phosphates, interspersed with particles of a dark, hard substance. These, when collected, turned out to be the *débris* of a slate pencil, which formed the nucleus of the calculus. I questioned the lady in the most delicate and persuasive manner I was capable of as to how this foreign substance could have entered this region of the body, but the only way in which she could account for the peculiar phenomenon was that in her childhood she might have swallowed the pencil! It was, I believe, one of the Georges who never could understand how the apple got into the dumpling. I leave it to you, gentlemen, who are much more intimate with the mysteries of the internal economy of the female sex than I am, to solve the problem as to how the pencil found its way into this woman's bladder.

The cystitis persisted for some time, necessitating the bladder being washed out daily by antiseptic and astringent lotions. On May 8th, a fortnight after the operation, I made a cystoscopic examination, and found that the bladder was quite healthy, both ureteral orifices normal, and that there was a puckered scar on the left of the trigone, in front of the left ureteral orifice, indicating the position in which the fistula had existed. This fistula had evidently been produced by one end of the slate pencil, covered by phosphates, ulcerating through the bladder and vaginal walls, and had rapidly closed when the source of irritation had been removed.

Stone in the bladder is, as you are aware, much more rare in females than in males. This is due to the urethra in the female being short and dilatable, the absence of a prostate, and the rarity of stricture of the urethra, so that small calculi passing down from the kidneys are not so easily arrested in the bladder in females as they are in males.

Among 1,047 cases of stone in the bladder operated on by me, there were twenty-five females, or about 2½ per cent. on the whole. Of these operations 861 were performed in India, seventeen being in females, or about 2 per cent., and 186 in England, with eight in females, or 4.3 per cent. From these statistics it might appear that the proportion of females to males afflicted with stone in the bladder in England is more than twice that in India. The disproportion I entirely attribute to the fact that in India the large majority of the female population is debarred through social prejudices from consulting a surgeon of the male sex.

Of these twenty-five operations for stone in females three occurred in my lithotomy days, before I commenced litholapaxy. These three occurred in children, and the calculi were removed by rapid dilatation of the urethra. All these were successful so far as the operation is concerned; but, unfortunately, in one instance, in which the stone weighed four and a-half drachms, incontinence of urine resulted, I fear permanently. Since commencing Bigelow's operation twenty-two cases of stone in females (seven children and fifteen adults) have come under my treatment, and of these twenty-one have been treated by litholapaxy with entire success. The remaining case was that of a woman, æt. 70. I attempted litholapaxy, but this stone composed of uric acid and weighing two ounces, was so extremely hard that though it was easily grasped by this my largest lithotrite, No. 18, English scale, I could make no impression on it, though I used all the force of which I was capable. The stone in this case I successfully removed by vaginal lithotomy. With my present experience I should remove it suprapubically.

Litholapaxy in females is, as a rule, not a difficult proceeding, the instruments employed being the same as for males. Even quite young female children admit large lithotrites and cannulae without any preliminary dilatation of the urethra. The only special difficulty met with is that, owing to the width and shortness of the urethral canal, the water which is necessary in the bladder

during the crushing of the stone is liable to rush out beside the lithotrite. This difficulty is obviated by getting an assistant to place the fore and middle fingers of one hand in the vagina and to press the posterior lip of the urethra against the instrument, a manoeuvre which prevents the water from flowing out. Litholapaxy in females is eminently successful, and the patient may be seen, as a rule, walking about a day or two after the operation. No forcible dilatation of the urethra being necessary, there is no incontinence of urine, that distressing sequel which sometimes follows the operation of dilatation. I have already referred to one such unhappy result in my own practice. Several similar cases from the practice of others have come under my notice since I commenced to practice in London.

One patient from whom I removed a calculus over an ounce in weight, by litholapaxy, was seven months pregnant. The details of this case are interesting, so I will give them.

Case.—M. C., a female, æt. 25, admitted to the Moradabad Hospital, May 11th, 1890, with symptoms of stone of one year's standing. Seven months gone in pregnancy. Great pain in the region of the bladder, which becomes so intolerable when she attempts to stand or walk that for three months she has had to keep lying down; this is evidently due to pressure of the gravid womb on the bladder, which contained a stone. When she desires to pass urine she has to insert her finger in the urethra, and push back the stone from the neck of the bladder. Next day I performed litholapaxy. The stone was at once caught by my No. 15 lithotrite, which had to be three times inserted before the calculus was completely crushed and extracted. Cannula No. 18 was employed. *Débris* of the calculus, which I pass round, are mainly urates and it weighs 477 grains. Next day the patient was sitting up and walking about her room untroubled by any symptoms. Discharged cured on May 17th.

This is a very interesting case, showing that litholapaxy can be performed in the last stages of pregnancy without the fear of causing a miscarriage. I hesitated at first about undertaking the operation till after the woman's confinement, but her miserable condition and the fear that the presence of a large stone in the bladder might greatly interfere with labour induced me to operate without delay.

THE FALLACIES OF "CANCER": AND THE MOST PROMISING DIRECTION FOR SCIENTIFIC RESEARCH.

By HERBERT SNOW, M.D. LOND., &c.,
Senior Acting Surgeon, Cancer Hospital.

At a moment when an august utterance has directed special attention to the subject of malignant disease; when on every side there is talk of research-laboratories, and of more or less costly schemes of investigation; when millionaires, to promote these, are being sedulously advertised for; and when the lay journals daily boom a new "cancer" "cure" or "astounding discovery," it may not be amiss to point out some of the almost innumerable fallacies which pervade that subject to its core. For until these are cleared away, or at least distinctly recognised and allowed for, there cannot possibly be any scientific progress whatever; and the treatment also must largely remain, as now, pure empiricism. The whole domain of cancer must continue for all practical purposes what it was lately styled by the *Practitioner*, "the darkest Africa on the map of medicine."

I. *Terminology and Nomenclature.*—The word "cancer" itself presents the initial difficulty; and supposing an authoritative investigation, would have first to be reckoned with. To talk of "cancer" at large is exactly tantamount to a discussion on "fever," and could lead to no more definite result. Each tissue develops its own

form of malignant new-growth, to which it would be idle to deny the designation of "cancer" or cancerous. Though the neoplasms resulting bear a general resemblance to each other in career, and often partially overlap in clinical features, yet the causation of each is essentially distinct, and the modes of development present fundamental differences.

On that tissue-basis (I submit the only one possible from a scientific point of view) we have to deal with nine primary forms of cancer, which may be considered *genera*. These arise respectively from epidermic epithelium, glandular epithelium, connective tissue, lymphoid tissues and lymph-glands, tubular gland-follicles, hair follicles, organic muscle-fibre, nerve tissue and endothelium. Then further appear a large number of secondary variants of the former, which may be aptly regarded as *species*. Thus the colloid, osteoid sarcomata; the melanotic sarcoma, and melanotic epithelioma, chloroma, intra-cystic forms of malignant growth, thyroid cancer, &c., &c.

It is of course admitted that the phenomena of malignant disease attacking the special female organs dominate professional conceptions of "cancer," and constitute what almost every writer upon the subject at large has in his mind's eye. But still malignant growths of the uterus and mammae, though numerically prevalent, constitute only a single group. And in any scientific inquiry, dealing for instance with causation, it is not permissible to consider a single section, to the exclusion of all the rest.

Then, in the ordinary nomenclature of malignant disease the utmost confusion is apparent. Some writers refuse the title "cancer" to sarcoma; on what grounds is not apparent. Three distinct forms of tumour are comprised under the term "alveolar sarcoma." The primary cancer of the lymph-glands and lymphoid tissues is often termed a sarcoma (from the meso-blastic origin of these structures and its significance in Cohnheim's almost obsolete theory). That highly elastic term may further denote (a) the true connective-tissue malignant tumour; (b) acute carcinoma, especially of the mamma; (c) the cancer of unstriated muscle, myo-sarcoma; (d) blastomata, the new growths from unobliterated embryonic vestiges; (e) endothelioma. Hence the same technical word is often used in widely distinct senses by different writers. Clinically and pathologically the phenomena of malignancy in pavement epithelium present important differences from those in secreting-gland cells; yet the word carcinoma is almost universally employed to signify both. And many more examples could be given.

II. Causation Fallacies.—Each individual case of malignant disease is preceded by well-recognised and ascertainable antecedents. In other words there is rarely or never mystery about the exciting cause of any given example.

To take the two leading genera, the exciting cause of epithelioma, the cancer specially of males, is the continued friction of a mucous membrane, i.e., direct irritation. On the other hand, the almost invariable precursor of a carcinoma, the cancer *par excellence* of the female, may be summarised as "*anything tending to preclude the tranquil devolution of organs which have passed their period of functional activity, and are entering on their final resting stage.*" Generally this is found on inquiry to have been depressing mental emotion, but exhausting toil or prolonged illness makes for the same effect; and occasionally, mechanical violence. The excitant of mammary and uterine carcinoma is most often indirect.

It is perhaps worthy of note that worry and trouble in elderly women may produce mammary lesions which are, primarily at least, non-malignant. Cystic degeneration of the mammae, and the solid adeno-fibromata of later life, own exactly the same causation as cancer, viz., perverted devolution of the organ. And even the huge uterine myoma is commonly preceded by well-marked signs of preceding congestion with functional derangement.

It is obvious that to bracket too closely together two varieties of disease owning such diverse modes of origin, to say nothing of subsequently divergent symptoms and clinical career, is a proceeding eminently unscientific. How much more so when all the remaining varieties

are confounded under a single heading! For any useful scientific purpose each and every form of malignant disease must be considered separately, at least in points of causation, unless or until we can discover some connecting link, such as a parasite, between them all.

III. The "Cancer Microbe."—No investigator has yet succeeded in establishing to the satisfaction of his fellows the existence of a microbe in cancer, nor since a considerable number were simultaneously proclaimed in different parts of the world, some seven or eight years ago, has anything been discovered to render its presence more probable.

Until then, the *a priori* difficulty which seems, if not absolutely to negative the parasitic theory, at any rate to render it highly doubtful and unlikely, still subsists. If there be a parasite in cancer it must behave altogether differently from every other yet known to science. A great gulf lies between the phenomena of every malady dependent on a microbe, and those of malignant disease. And it is very difficult to conceive how any such extraneous factor could generate that reduplication of normal tissue, though with perverted details—for example, mammary tissue growing in the liver, rectal structures deposited in the lung—which characterise cancer.

IV. Microscopic Reports.—Even the microscopic examination of growths, malignant or supposed to be such, is considerably vitiated by the custom of relying upon cut sections only. The preparation of thin sections accurately discloses the mutual relations of the constituent cells. It almost entirely disguises the shape of the individual cell itself. Under the microscope we see the stained nuclei only. Whereas an appreciation of the exact shape of the whole cell is often of the highest importance towards a correct diagnosis. From the examination of many hundreds of slides, I have been led to regard the spindle-shape as absolutely characteristic of all malignant new-growths really arising from the connective tissues, and so properly designated sarcomata. In the prepared thin section, this feature is frequently indistinguishable.

Another point which is essential to the differentiation of benign from malignant lesions, and which is, I think, often neglected by the microscopist is the army of leucocytes always around the cell-columns of an infiltrating carcinoma; absent in a simple hypertrophy, as when the uterine cervical glands are concerned in the familiar granular erosion.

V. The Path most Promising in Scientific Results.—The absence of any discernible congenital influence or hereditary predisposition in the great majority of cancer cases seems fatal to the embryonic theory of Cohnheim and to the pangenesis invoked by Darwin. And so far, no microbe is forthcoming in spite of several years of laborious search.

The only general theory of cancer which can be said to hold the field is the Autocytic. It explains, with reasonable adequacy, all the phenomena. It is a pithy expression of the actual clinical and histological facts, and it complies with the first desideratum of Darwin, "a good working hypothesis."

The Autocytic theory regards as the essential mechanism of all cancer-growth the escape of the particular cells involved from the control of the nervous system. These cells then become parasites, or rather autositae. They are rebels against the central power, and hence forward prey on the surrounding tissues of the body until death is the final result.

The characteristic features of all malignant or cancerous phenomena, which differentiate this class of diseases from all others, are: (a) Uncontrolled and heterogeneous proliferation of normal cells. (b) Progressive erosion of the surrounding healthy tissues by the new cells. (c) Auto-infection, or diffusion to distant parts. These three salient marks are, by this theory, and this alone, rendered fairly comprehensible.

Until some better explanation appears, it would seem the best policy to hold this tentatively valid, and to follow up its indications. In my humble view, the most promising path is by research among the lowest cellular organisms, the little amoeba and its congeners. By investigating the life-history of these creatures, by

experimentally inducing disease among them, by watching the phenomena of that disease, by gradually working upwards from the lowest to the highest, we shall ultimately be able to comprehend the great mystery of cancer—why the natural constituents of our body become metamorphosed into its deadly foes.

VI. Non-surgical Treatment and the most Hopeful Path of Improvement.—We are often able to hold the course of cancer remarkably in check by the judicious administration of opium, sometimes with cocaine. But, so far, the whole vegetable and mineral kingdoms, and every law of Nature known to man, have been in vain appealed to for a genuine "Cancer-cure."

In 1898 (*Lancet*, October 15th; *MEDICAL PRESS AND CIRCULAR*, November 9th) I pointed out that the nuclear or cell-particles emanating from malignant new-growths must be destroyed to a considerable extent before their successors can gain a foothold in the lymph-glands, producing the ordinary metastatic phenomena. Personally, I have, on this point, no doubt. So far as I can see, only thus can be explained the remarkable influence of proximity upon the secondary gland-infection of carcinoma or epithelioma.

If, for example, one of these lesions arise close to a lymph-gland chain, as at the axillary border there is a rapid enlargement of the adjacent glands, which quickly attain a larger bulk than the primary deposit, and far outstrip it in rapidity of clinical course. On the other hand, if an epithelial ulcer be developed on the fingers or toes, the axillary or inguinal deposits appear very tardily; in other words, the particles of protoplasm which pass into the lymph-currents are rendered inert, either there or within the lymph-gland, until finally triumphant by force of numbers.

Another highly significant point in this connection is the behaviour of the axillary glands with true mammary sarcoma. They are never distally infected, never show metastatic deposit, are implicated only when there is general blood-infection, or by contiguity. No one can doubt that the nuclear particles of sarcoma are conveyed to these glands, though they do not take root therein, like those of carcinoma. They must be destroyed either in the gland or the lymph current. In one of my own cases the glands contained no sarcoma-growth, but were all partially converted into little cysts filled with blood-clot.

Whether the contagious cancer particles are destroyed in the lymph-current or within the gland itself remains of course to be tested. And it is also uncertain whether the principle can be actually brought to bear for therapeutic purposes. These are questions for the prospective laboratorer.

After an exhaustive study of malignant phenomena for many years, I would strongly urge on these bodies the investigation of the principle asserted before any other; being convinced that it holds out by far the most hopeful chance of practical success in cancer-treatment.

Clinical Records.

DERMOID CYST OF THE LEFT OVARY WHICH CAUSED OBSTRUCTION TO DELIVERY. (a)

By J. FURNEAUX JORDAN, M.B., B.Ch., F.R.C.S.
Surgeon to the Hospital for Women, Birmingham.

On February 12th last, I received an urgent summons to a consultation with Dr. Norris, of Perry Barr, upon a case of labour in which delivery was prevented by a pelvic tumour, probably a cyst.

The patient, æt. 29, and married between four and five years, had one child three years old. No pelvic trouble had been suspected until, after she had been in labour three or four hours, the head failed to descend. On examination I found the head, surrounded by the dilated cervix, jammed behind and above the pubes, while behind and below it was a firm, immovable,

moderately tense, and smooth swelling. I decided at once against "tapping in the dark" as a means of relief. I thought it might be possible to incise the posterior vaginal fornix, tap and remove the cyst, and then deliver the child, but found it absolutely impossible to pull down the cervix so as to bring the vaginal fornix within working distance. Under the idea that the child might still be alive I proceeded immediately to open the abdomen, and deliver by Cæsarean section, for it was clear that the cyst could not be removed till the child was out of the way, nor the child delivered by the pelvic route while the cyst remained where it was. Unfortunately, I was just too late to save the child's life. After closing the incision in the uterus by a continuous silk suture, I removed this dermoid cyst. It was deep down in the pelvis, densely adherent everywhere and obviously could not have been removed by the vaginal route even if I could have easily reached the posterior fornix.

Tapping would have been probably disastrous and certainly ineffectual.

The patient made an uneventful recovery.

MULTI-NODULAR MYOMA OF THE UTERUS AND BOTH BROAD LIGAMENTS REMOVED BY SUPRA-VAGINAL HYSTERECTOMY. (a)

By J. FURNEAUX JORDAN, M.B., B.Ch., F.R.C.S.

The patient, æt. 40, and married fourteen years, had had no children and no miscarriages, nor any excessive loss at her menstrual periods, but in the last year or two had occasionally gone a little over four weeks between two periods. She was first seen by me early in November, four months after she had detected a lump in her abdomen. On examination then "the lump" was found in the right groin, but the greater part of the tumour occupied the pelvis. Pain was persistent, but not severe. On her admission into the Women's Hospital on January 13th of this year I found that there had been a decided increase in the size of the tumour; the lump in the right groin caused a marked prominence; a second and smaller lump occupied the left groin, caused a slight prominence there, and there was a depression in the abdominal surface between the two. The pelvis was practically blocked by the tumour, especially at the sides. The general condition of the patient was good, her pulse slow and uniform; her urine contained no albumin, and was of specific gravity 1021.

On January 15th I performed a supra-vaginal hysterectomy, performed by Kelly's method in the Trendelenburg position. I went down on one side, divided the cervix at the level of the internal os, and ascended on the other side. I could not, however, divide the broad ligaments in the usual way, for portions of the tumour had completely invaded both the right and left ligaments, and the division of each broad ligament, therefore, really consisted in the enucleation of the tumour from its interior. The right and larger portion of the tumour had lifted the peritoneum from the iliac fossa, and the cæcum and the vermiform appendix were spread out upon its upper surface, and I found it advisable to remove the appendix. It was impossible to deliver the tumour through the abdominal incision even to the slightest extent, until all its attachments had been divided, as the greater part of it lay beneath the peritoneum. After its removal the out edges of the peritoneal covering were easily brought together in a line across the floor of the pelvis, and united by a continuous suture of fine silk. With the exception of a small stitch abscess, which occurred about the tenth day, her recovery was good. I had, however, some difficulty in getting the bowels to act on the second day; it was imperative that they should do so, for there was very great distension of the abdomen. After repeated turpentine enemata had failed, a very high injection of olive and castor oils, followed by gentle massage of the abdomen, proved effectual in getting rid of large quantities of flatus and fecal matter.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD MARCH 13TH, 1902.

Dr. J. HALLIDAY CROOM, President, in the Chair.

SPECIMENS.

Mr. J. FURNEAUX JORDAN showed (1) A Dermoid Cyst of the Ovary—an Obstacle to Delivery; (2) A Uterine Myoma removed by Supra-vaginal Hysterectomy. Notes of these cases will be found in another column under the heading "Clinical Records."

Dr. SPANTON showed a

MYOMA OF THE UTERUS,

weighing eight and a half pounds. He said he brought the case forward as a particularly interesting example of one of the many forms of myoma with which one had to deal. It occurred in an unmarried lady, æt. 37, to whom of course a tumour of that size was an enormous burden. It began, as was often the case, very obscurely, and with scarcely any symptoms at all until a very few months before he saw the patient in January. She had metrorrhagia with a certain amount of pain, and the increase in the size of her abdomen was sufficiently gradual and suspicious to make the friends keenly alive to the possibility of pregnancy, and to the outward feel it was just one of those cases which might very easily have misled anyone. He found it was a myoma, and operated by the usual method, making flaps and tying each broad ligament in three portions, leaving the cervix, draining the cervical canal into the vagina, closing the flaps with catgut, and putting interrupted sutures through the peritoneum in the ordinary way. Although the tumour probably suggested that enucleation might have been possible, at the time of the operation such a course appeared quite out of the question, there was no projection whatever into the interior of the uterus, and the tumour appeared to be entirely embedded in the uterine wall; he therefore thought that he had adopted the right course under the circumstances. A little over a month from the operation she went home perfectly well. The case illustrated in some respect the advances which had been made during the last few years in the surgical treatment of such cases and the very satisfactory results following such treatment.

Mr. ROBERT O'CALLAGHAN showed

FOUR FIBROIDS AND UTERUS REMOVED BY HYSTERECTOMY.

This specimen was removed from a woman, æt. 39. When admitted into hospital she was thought to have an attack of acute hepatitis which turned out to be a localised peritonitis in one of the fibroids, which was securely attached to the liver by old adhesions; there being a long pedicle between this one fibroid and the others it appeared as if it was a separate growth attached to the liver. On opening the abdomen this fibroid was found to be strongly adherent to the liver and apparently part of it; it was also attached to the hepatic flexure of colon and great omentum. It required considerable force to break it away, after which there was some smart bleeding, which was for the moment packed with a large, hot sponge. The smallest fibroid was fast also in Douglas's pouch; after delivering this he removed the uterus which contains two large fibroids and the appendages. The patient had a smart attack of localised peritonitis, which yielded to three grains of calomel followed by a seidlitz powder, and turpentine enema, but is now quite well, four weeks after operation.

Mr. ROBERT O'CALLAGHAN also showed

FIBROID UTERUS AND CYSTIC OVARIES REMOVED BY HYSTERECTOMY.

This specimen was removed from a patient sent to me by Dr. Vintras, æt. 40. She had very little trouble until a year ago, when menstruation became very profuse, reducing her to a bloodless condition, and her bladder became so irritable that she could not retain urine for more than an hour unless lying down, and constipation, amounting to obstruction, gave her much

trouble. On opening the abdomen this was easily accounted for, as both ovaries, which were adherent, contained large blood cysts (rupturing on enucleation), and this condition tilted the uterus forward, at the same time fixing it well down in the pelvis. She made an excellent recovery, and is now, two weeks after operation, convalescent.

Dr. MACNAUGHTON-JONES said the Fellows were very much indebted to those who had brought the specimens forward, and there were one or two points connected with them which were interesting. Mr. Furneaux Jordan's first specimen showed how foolish it was to lay down any particular rule with regard to the method or technique of removal of myomata. Looking at the specimen and recognising the extreme difficulty of freeing the masses at either side from the broad ligaments without injury to the ureters, the critical point in the removal of such deep-seated pelvic myomata, Mr. Jordan's success showed clearly the superiority of the ligature over any other method of removal. He had himself never tried the application of any form of forceps pressure or clamping the ligament on either side in a similar case; but it was only necessary to look at the specimen to see how extremely difficult it would be to secure the ligaments at either side of such a tumour with a large clamp, without injury to the ureter and other trouble, and what risk would be attendant on the attempt. With regard to the specimen shown by Dr. Spanton, possibly if Dr. Spanton had a similar case in which he could be sure that the tumour was encapsuled he would divide the capsule and then rapidly enucleate its contents. The removal of the capsule made the removal of the myoma under such circumstances particularly easy. There was one point about Mr. O'Callaghan's tumour which he would like explained. He (Dr. Macnaughton-Jones) had never before heard of a uterine myoma which had an attachment to the liver, and would like to know the nature of the attachment. A peritoneal attachment to the transverse colon could be understood, but an attachment which involved the liver substance proper would be a unique, and would surely lead to profuse hemorrhage, and one would expect that the hemorrhage would be fatal. He simply wished to have the statement quite clear for the sake of the records.

Mr. MANSSELL MOULLIN congratulated Mr. Jordan on the successful termination of the case. Such cases had sometimes a way of developing abdominal symptoms at the end of a week or ten days, such as flatulence and abdominal distension and tenderness, which caused their medical attendants great anxiety.

Dr. SNOW, in reference to what had fallen from Dr. Macnaughton-Jones on Dr. Spanton's specimen as to enucleation, said that this was the class of tumour on which he, Dr. Snow, following upon the footsteps of Mr. Lawson Tait, had recently read a paper; he described as a monoma a single tumour, steadily increasing in size until it produced death; and he wanted to ask whether Dr. Spanton would consider the growth malignant. If so, he thought enucleation would be the worst possible policy, because in a very short time there would be recrudescence or recurrence.

Dr. WILLIAM TRAVERS said he simply wished to draw attention to one short line in Mr. Furneaux Jordan's admirable report. Speaking of the discomfort and tension and possible peritonitic symptoms on the second or third day, it was a great comfort to all, and especially early operators, to remember that the pulse was no doubt, in the first few days, the greatest guide in such cases. The signs which supervened on the second day or the third day had naturally made Mr. Jordan anxious, believing the mischief to be traumatic, and that it arose from the handling of the tumour, for the handling had to be somewhat roughly done for the purpose of clearing out the growth. But he (Dr. Travers) thought that, generally speaking, there was not enough notice taken of the pulse as an indication of the condition of affairs. He felt very strongly that the chief guide in the first few days was the pulse, and if that kept below 100, and better still if it kept at about 90 or below, one

could be content to leave things alone. He had no doubt that these early peritonitic symptoms accounted for the adhesions, which were often very considerable, but later on might become troublesome.

Mr. RYALL said he was much interested in Mr. O'Callaghan's case, as it was one of those which proved how fibro-myoma could become adherent to some of the intra-abdominal viscera, and very often be a cause of error in diagnosis. He remembered being present at an historic operation upon a woman for an enlarged spleen. Several very eminent men were present, and one very eminent lady doctor. They all felt the tumour and even detected the notch in the spleen, but when the abdomen was opened, the tumour was found to be one of those pedunculated fibro-myoma with an extremely long pedicle, and one without any intimate connection with the uterus. He believed the ancient pathologists used to say it was impossible for fibro-myoma of the uterus to be adherent to the small intestine; but adhesions frequently did occur between fibro-myomata and the small intestine, not to mention other viscera. He thought Dr. Spanton was to be congratulated for not trying enucleation in his case.

The President said that Mr. Furneaux Jordan deserved the very greatest possible acknowledgment for his success in the case in which labour was complicated by an ovarian tumour. He had in a very similar one himself met with the reverse. The patient was in labour, and the medical man in attendance had put on forceps, and in pulling the foetal head down he crushed the tumour. There was no possibility of removing the tumour by the vagina, and the woman died. With regard to Dr. Spanton's case and Dr. Snow's remark that monoma was usually malignant he, the President, had had a very curious experience. A great many years ago Mr. Tait, when visiting Edinburgh, had asked him, the President, to provide him with two show cases, upon which he could operate for the benefit of the profession. He selected one, for removal of the ovaries in order to check the increase of a fibroid tumour, a single myoma such as Dr. Spanton had removed. The lady of course made an excellent recovery, and the case was recorded in Mr. Tait's book. But the lady died long afterwards, and she was the only woman he had ever known to have died directly from uterine hemorrhage due to a myoma. He accordingly wrote to Mr. Lawson Tait to tell him that his operation in that instance had been unsuccessful. He received a most characteristic reply saying that the fault was his, Dr. Croome's, for he had mistaken a sarcoma for a myoma. It certainly seemed to be a myoma exactly like that shown by Dr. Spanton. He scarcely knew what would be the best course in dealing with monomata. He could not say he would be disposed to enucleate; at the same time removal of the ovaries did not seem to offer much hope. Distension to him was a very serious feature, and he quite agreed with others who had spoken that the pulse was the indication as to the gravity of the case. He thought the treatment adopted had been the best.

Mr. J. Furneaux Jordan, Mr. O'Callaghan, and Dr. Spanton having severally replied to the criticisms and inquiries of the members who had discussed their cases, Mr. FREYER (as guest) showed a specimen of

MYOMA OF THE BLADDER,

first thanking the Society for the honour of inviting him to bring the specimen. The patient was a married woman, *et. 24*, who had been married five years when she came under observation. She was confined of a child a year after marriage, *i.e.*, four years before she came under medical notice, and nothing unusual occurred. At a second confinement two years later there was considerable difficulty, the doctor having to push the tumour back out of the way of the foetal head. Some time after that she was admitted into a London hospital, and a tumour of the bladder being diagnosed, the urethra was dilated and the tumour scraped, but with no good result. She came under observation at St. Peter's Hospital on October 15th last year. She was then suffering from severe hæmaturia, from great straining to pass her water, the straining having been

necessary by the retention of urine, which sometimes had to be relieved by the passage of a catheter, and at other times by passing the hand up the vagina and pushing the tumour out of the way. On October 30th he operated, opening the bladder supra-pubically, and found the tumour he had described. He nicked the mucous membrane covering the tumour, and with his finger separated the mucous membrane from the tumour and gradually enucleated the tumour without any difficulty whatever. The patient made an uninterrupted recovery and was discharged from hospital a month afterwards and was now quite well.

The President thanked Mr. Freyer for his most instructive case, which it was very kind of him to come and show. The specimen was a very interesting one, and, as far as he knew, absolutely unique.

Dr. MACNAUGHTON-JONES showed the chart of a patient after hysterectomy for myoma. While she had made an excellent recovery without complications of any kind, there had been a remarkable pulse rate. It became dicrotic a few days after operation. Finally, at the end of the first week, it reached 190 in the minute, while the temperature range varied, though it did not at any time reach 102°. This rapidity of pulse continued for over a fortnight after operation. The respirations all through were normal.

Dr. MACNAUGHTON-JONES also showed a drawing of the fundus in which there were hæmorrhagic extravasations into the retina, the secondary consequences of albuminuric retinitis occurring during pregnancy. The patient had been operated on by him for a parovarian cyst, which had caused pelvic peritonitis. After the removal of the affected adnexa she became pregnant, and the vision of both her eyes was most seriously affected. She was delivered at full term, and her vision was now perfectly normal.

The President read a paper on "An Interesting Case of Ovarian Abscess," which we hope to publish in an early number.

Mr. FREYER read a paper on "Stone in the Female Bladder," which will be found in another column under the heading of "Original Communications."

In the discussion the President, Mr. Furneaux Jordan, Dr. Snow, Dr. Travers, Dr. Macnaughton-Jones took part, as well as Dr. Spanton, who showed stones of 70 and 180 grs. and a slate pencil, 2½ ins. long, removed from children without leaving any incontinence; he occurred, however, with Mr. Freyer that litholapaxy, or the supra-pubic operation in the case of very large stones, was now the treatment to be adopted.

Mr. SPANTON showed the following specimens:—

1. In the course of some remarks on Mr. Freyer's paper, showed a mixed calculus, weighing 180 grs., removed entire from a girl, *et. 5*, by urethral dilatation. The operation was not followed by incontinence or any untoward result.

2. Another calculus, weighing 70 grains, from a child, *et. 3*, removed in a similar manner, and followed by complete recovery.

3. A piece of slate pencil removed from the bladder of a girl, *et. 11*, measuring over 2½ inches in length, each end of which was fixed in the bladder wall. Dilatation and forceps were employed. Recovery was immediate.

Such satisfactory results did not, however, always follow dilatation, and future practice will no doubt lead to litholapaxy in most cases, and suprapubic lithotomy in the case of unusually large stones, as advocated by Mr. Freyer.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD IN THE ROYAL COLLEGE OF PHYSICIANS
ON MARCH 14TH, 1902.

Dr. ANDREW HORNE in the Chair.

Dr. T. HENRY WILSON, Hon. Secretary, exhibited for Dr. Glenn an uterus removed by retro-peritoneal hysterectomy, showing peculiar venous attachments.

Dr. ALFRED SMITH exhibited three fibromatous uteri, showing mucoid degeneration.

Dr. PUREFOY exhibited a fibroid uterus and a specimen of ruptured tubal pregnancy.

The chair having been taken by Dr. Purefoy, Dr. HORNE exhibited a specimen of a large uterine polypus. On resuming the chair, Dr. HORNE called on Dr. PUREFOY to read his "Report of the Rotunda Hospital for the year 1900-1901."

During the year, 1,905 women were admitted to the maternity department of the Rotunda Hospital, of whom 1,610 were confined, and 300 were discharged not being in labour. Among those treated were found some of the rarest concomitants of pregnancy, viz., emphysema, puerperal aphasia, and pulmonary embolism. During the year, three deaths occurred: (1) moribund on admission; (2) an emaciated cachectic patient, some days in labour before admission, succumbed after Cæsarean section, rendered necessary by uterine fibroids; (3) an elderly patient with contracted pelvis, after induction of premature labour, unusually protracted by inertia of uterus and morbid adhesion of the placenta. The dispensary attendances during the year were 10,741. In the extern maternity department, 2,175 cases were treated, including 286 cases of abortion, eighteen of accidental hæmorrhage, six of placenta prævia, twenty-seven of *post partum* hæmorrhage, and seven cases of prolapse of funis. In the intern maternity 1,616 cases were treated, of whom 549 were primiparæ. The operations performed included 66 forceps cases, 24 cases of the manual removal of the placenta, 10 cases of version, and one case of Cæsarean section. There were 19 cases of accidental hæmorrhage, 9 of placenta prævia, 36 of *post partum*, and one of secondary hæmorrhage. The presentations included 43 cases of breech, 5 of face, 8 of footling, 20 of occipito-posterior, 6 of transverse, and 10 cases of prolapse of the funis. Of multiple pregnancy, there were 14 cases, all of which were twins. Episiotomy was practised in 18 cases, chiefly as an aid to forceps extraction—the single incision in the mesial line was invariably adopted. Ophthalmia occurred in four cases during the year. In all the attack was mild, and had entirely subsided before the infant left the hospital. A red vaginal discharge, having the character of menstrual fluid was observed in two infants, beginning on the second day after birth, and lasting four or five days. The causes of morbidity included mastitis in four cases, influenza in two, bronchitis in three, phthisis in one, pleurisy in one, mania in one, syphilis in two, erythema in two, inflamed piles in one, rheumatism in one. In twelve cases the cause of morbidity was not ascertained. The report dealt very fully with the case of that rare and interesting condition puerperal aphasia, of which Dr. Purefoy's case is an example. The patient was æt. 23, a primipara, of healthy appearance. Her pregnancy had proceeded most favourably till the beginning of the ninth month, at which time her husband, one day returning from work, found her in bed and unable to speak anything but the word "Yes." At the same time he observed large quantities of vomit on the floor. The case of pulmonary embolism occurred in a primipara, æt. 34, who made a good recovery. Messrs. Johnson and Sinclair record seven cases of this affection, but this is its first occurrence during Dr. Purefoy's term of mastership.

At the termination of the reading of the Report it was decided to postpone the discussion until the next meeting of the Obstetrical Section, and the meeting terminated.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

GENERAL MEETING HELD FRIDAY, MARCH 14TH, 1902 (at the Medical Society's Rooms, Chandos Street).

President, Dr. JOHN MACINTYRE, F.R.S.E., in the Chair.

Dr. MCCALL, of Bournemouth, showed an advanced case of tuberculous laryngitis, which had been exhibited last year and had remained well for nine months without further intra-laryngeal treatment.

Mr. MAYO COLLIER showed a case of deaf mutism, shown at the last meeting, in which there was continued improvement following the removal of impacted cerumen.

The PRESIDENT exhibited a foreign body with an X-ray photograph, showing its position in the antrum of Highmore. The patient had been operated on in Paris for empyema through the alveolus seven years previously, and was wearing a silver tube with a soldered flange. This last had become separated, and the tube had disappeared into the cavity, as was proved by Röntgen irradiation; Dr. Macintyre, to remove this, operated through the canine fossa, after which the empyema was promptly cured.

Mr. BARK (Liverpool) remarked that this case was important as demonstrating that opening of the antrum through the alveolus was an incomplete operation, and that in all cases the cavity should be entered through the canine fossa.

Dr. WOODS (Dublin) mentioned two instances, one in his own practice, of a similar accident.

Mr. LENNOX BROWN thought that in early and dental cases the alveolar operation was sometimes sufficient. The accident was not so very uncommon, and could be avoided by the cannula being made of gold and in one piece.

Dr. KELSON urged the importance of making a counter-opening in the nose in all these cases.

Dr. DUNDAS GRANT opened a discussion on THE DIAGNOSIS AND TREATMENT OF VARIOUS FORMS OF NERVE DEAFNESS.

We propose to publish the author's paper in full in our next issue.

The discussion was adjourned to the next meeting.

The annual dinner of the Association was held at the Café Royal in the evening.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, MARCH 13TH, 1902.

CLINICAL EVENING.

THE following cases were shown:—

Lupus healed by X-rays, Dislocation of hip, and Ten cases illustrating treatment of chronic ulcers of legs, by Drs. Alexander and Peet.

Tuberculosis of the skin of arm, by Drs. Alexander and Martin.

Molluscum fibrosum with progressive muscular atrophy, Muscular tremors, Two nervous cases for diagnosis, Deformed hand, Locomotor ataxia and early rodent ulcer, and advanced rodent ulcer, by Drs. Alexander and Jackson.

Wired fractured patella, Repaired sciatic nerve (division by bullet), Cured popliteal aneurysm, and Serous meningitis (?) cure, by Mr. Thelwall Thomas.

Pseudo-hypertrophic paralysis, Osteo-arthritis of the spinal column, and Ascites treated by frequent tapping, by Dr. T. B. Bradshaw.

Rodent ulcer, fifteen years duration, by Dr. W. T. D. Allen.

Favus, and Lymphadenoma, by Dr. Ernest Nevins.

Sarcoma of the buttock, Favus, by Drs. Nathan Raw and R. T. Bailey.

Edema of the hand, by Mr. Hawkins Ambler.

Epidermolysis bullosa hereditaria (mother and daughter), and rodent ulcer of nose and eyelids and epithelioma of neck, X-ray treatment, by Dr. Stopford Taylor.

Primary syphilis in a septuagenarian, and Psoriasis (inveterate type), by Dr. Frank H. Barendt.

Series of lupus cases, treated by X-rays, Finns rays, and urea, by Dr. Leslie Roberts.

Growth on the conjunctiva (fibroma?), Tuberculosis of the cornea, and Varicocele of the orbit, by Mr. R. J. Hamilton.

Traumatic dilatation of the orbital veins, Wound of the lower eyelid involving the internal rectus muscle, and Rupture of the retina (golf ball), by Mr. Edgar Stevenson.

Demonstrations were given by Dr. Thurstan Holland

of a bullet in the heart (X-ray), and by Mr. Edgar Stevenson of Haab's electro-magnet. Radiographs, Dr. David Morgan.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 22nd, 1902.

THE *D. Med. Zeit.*, March 13th, gives a note by Prof. Condamin on

A NEW METHOD OF TREATMENT OF PERSISTENT VOMITING OF PREGNANCY.

Although it cannot be said that the principle is altogether new, it is still so excellent that it should be more widely known than it is. The Professor sees in such vomiting a sign of intoxication and an indication for removal of the toxic substance, whatever it may be. It is his constant endeavour to provide a substitute for the induction of the abortion that such cases generally end in. For some time past he has invariably been able to dispense with this by adopting the following line of treatment:—

Absolute abstinence from food for from eight to ten days. Daily injections into the rectum of three to four litres of artificial serum in quantities of 300 grammes with or without the addition of opium. In case of absolute intolerance on the part of the rectum, hypodermic infusion. After ten or twelve days' abstinence from food, gradual return to feeding by the mouth.

The *Monat. f. Geb. & Gyn.*, 14-4, has an article on

DISTURBANCE OF LABOUR AFTER VAGINO-FIXATION OF THE UTERUS,

by Dr. Ruhl, of Dillenburg. He claims that in but very few cases in which disturbance of the course of labour is met with after vagino-fixation, is this really due to the operation itself, but rather to circumstances connected with it. In five of the cases considerable complications were present, which in part rendered the fixation unusually firm and extensive, and made the cervix somewhat difficult of access. It is, at least, not improbable that natural delivery would have been out of the question in some cases. There was no operation, and no method that might not be followed by unpleasant circumstances, and it was remarkable that so few were met with after such an operation as vagino-fixation, when one would expect it. The results were very much in favour of vagino-fixation, as compared with ventro-fixation.

At the Hufeland Society, Hr. Jolly discussed the OPTIC APPEARANCES IN MIGRAINE AND THE THEORIES OF ITS CAUSATION.

The base of the address was a series of observations made on himself. There was a glistening scotoma as usual. Quite a number of observations had been made, and these had been collected first by Charcot, then by Gowers and others. Then a few years ago appeared the monograph of Antonelli. The scotoma might appear in one of three forms. The one-sided, in which the second eye was normal, was rare. The second form was that in which it was central on both sides, commencing in the periphery of the field, then gradually extending over the whole, and finally becoming fixed in the centre. In the third form one-half of the field of vision is affected as in hemianopsia.

The speaker's scotoma belonged to the latter category. It first came on in one eye in his ninth year, after an injury. He had suffered from migraine in his youth, increasing towards evening, and going off while asleep. There was loss of appetite, but no nausea nor vomiting and those wine flushes were never present. Towards the end of this student-time he became quite free, and as the scotoma first appeared in 1871 he was surprised and frightened. The shiny appearance came from one side and prevented him seeing, disappeared after a time outwards, and left an intense headache behind. Vomiting never took place. A similar attack took place some years after. The attack was even then very characteristic, and was repeated with short pauses through the nineties.

The phenomenon ran the following course: A cloudy speck appeared to the right or left or below, the mid line remaining free. It was not a bright scotoma, but a growing grey cloud that completely obscured the object. This phase lasted from a few to fifteen minutes. In the second phase a bright figure bordered by zigzag lines took the place of the cloud, sometimes glistening like gold, sometimes like silver, with the colours of the spectrum at intervals. Then his figure enlarged, and whilst this was going on the inner part cleared, and then vision returned, whilst outwardly vision was still absent. Then the area widened more and more. The middle line was never passed. The zigzag line disappeared outwards, left a sense of blinding, and then all passed off. Sometimes the various phases were shortened. It was remarkable that the glittering scotoma sometimes appeared the reverse way—from without inwards. There were therefore constant symptoms to be dealt with. The onset of the headache had still to be mentioned. The phenomenon, at first disagreeable, was not so later on. A certain feeling of pressure in the eye was to be noted. In some cases the headache was more violent than others, but never very lasting. It always disappeared in a few hours. It must be assumed from both eyes being affected that a part of the brain centralwards from the chiasma must be the part implicated.

It was not the cortical part, as had often been stated in recent times. The grounds for such an assumption would not hold together.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 22nd, 1902.

OPERATIVE ASCITES WITH COCAINE.

PAL exhibited two patients at the "Gesellschaft der Aerzte" to demonstrate the advantage of "Talma's method," as Pal designates it. Both patients suffered from hepatic cirrhosis.

The first was a man, æt. 38, who was anæsthetised with cocaine on January 15th, 1901. The omentum was fixed so that the space between the bowel and peritoneum should be as great as possible. In a short time after the patient had an epileptiform fit with hemiparesis similar to that described by Eck in his experiments on animals, when a fistula existed between the portal artery and vein, from which he recovered after treatment with bromides. Hæmatemesis was also present at one period.

The second case was that of a cooper, *æt.* 47, suffering from hepatic cirrhosis with ascites. Both patients recovered.

Pal has operated in this way on sixty cases, two-fifths of which proved satisfactory. Pal referred to five cases operated on by Frunk, two of the patients dying, but not in consequence of the operation. The other three had to be tapped later.

Eiselsberg related a number of cases in which he had operated by Talma's method, and in two of the cases he had to suture the spleen. In none of his cases did the ascites disappear, but repeated tapping was followed by ultimate success. As to Pal's hæmatemesis, this, he admitted, was a grave symptom, as it appears to be due to a retrograde embolus which aggravated the prognosis.

Frunk said he had performed seven operations recently with Schleich's anæsthetic on account of cardiac trouble associated with the cirrhosis. In many of the cases he found the omentum greatly shrunken, so that a wide area had to be brought into contact with the abdominal wall in order to obtain the necessary anastomosis. In one case he connected the appendices epiploicæ with the large intestines and that patient did very well. As a rule, however, connection with the parietal peritoneum was enough, although it might be necessary in some cases to connect it also with the muscular tissue.

AMPUTATION ABOVE ANKLE, OR SUPRA-MALLEOLAR AMPUTATION.

Eiselsberg next demonstrated a patient whose foot he had amputated just above the ankle. Success had always been difficult to ensure in this operation, as the covering was so small and the stump too tender to allow of the use of an artificial appliance. To obviate this drawback Bier attempted to follow Pirogoff in his operation on the tibia by cutting out a piece of bone, leaving the periosteum to cover the cut end. Bunge tried a similar method, but scooped out two or three centimetres of the medulla in order to prevent the formation of a great amount of callus. After healing he commenced early massage, walking about on a mattress, &c., to reduce the sensitiveness of the stump.

Eiselsberg now proposes a long apparatus made of wood with a fine rim of iron, ten centimetres broad, over which is fitted a tight rubber support which holds the stump tight. He claims for this apparatus that it is cheap (*4s. 6d.*), and weighs only one kilo=2.2 lbs.

He also showed an instance of amputation by Bier's method in a young man, *æt.* 19, when locomotion was still very ungraceful.

Mozkovicz showed a patient, *æt.* 64, on whom he had performed Bunge's operation with perfect success. Bunge's method, he affirmed, was superior to Bier's, as there was less bone sacrificed.

Schnitzler said that none of them had mentioned Brun's efforts to cover the bone by a sort of osteo-plastic operation. Owing to the cicatrix not being on the bearing surface the stump was a very useful one for any appliance to be fitted to.

NON-COAGULATION OF LEUCOCYTHÆMIC BLOOD.

Herman next gave an account of his experiments on the blood of leucocythæmic patients, which Ludwig twenty years ago affirmed was uncoagulable after death, although it contained albumin, which was in the form of a peptone. This, he said, might be generally true,

but he had found that blood newly drawn from the veins might not contain it, though it was present after three days. He gave the particulars of a case of lineal-myelogenic leucocythæmia. The fluid was kept sterile and therefore could not be due to germ action, although a ferment is assumed to be present.

This principle could be separated by alcohol, filtration and drying, and with albumin in an alkaline solution it acted as a digestive. It acts like tryptic ferment which is destroyed by heat, but can still be obtained from the non-coagulable blood as an albuminoid body.

The Operating Theatres.

ROYAL FREE HOSPITAL.

OPERATION FOR REMOVAL OF SARCOMA OF ORBIT.—

Mr. H. WORK DODD operated on a woman, *æt.* 71, who had been admitted for a growth in the left orbit. Three years ago Mr. Dodd had operated on this patient, doing iridectomy in both eyes for double glaucoma. At this time there was no indication of the present growth. After the iridectomies the right eye did remarkably well and continued in a good state up to the present time; but in the left eye the pain still continued to come on at intervals, and a year after this iridectomy Mr. Dodd advised the patient to have the eye removed on account of the pain. She declined operation, and was lost sight of until the present time. During the intervening period she stated she continued to have repeated attacks of pain in the left eye. About eight months ago the eye began to get large, to swell, and to become red. The swelling varied in size at times, but the pain became more and more severe. She also had pain in her neck on the left side, and a swelling was noticed in this situation, which remained at the present time. For some time past there had been a watery discharge from the growth, and lately this discharge had become yellow. On admission it was elicited that there was nothing in her family history bearing on the present disease; her general condition appeared to be fairly normal. The abdominal wall was rather rigid, and the superficial veins were somewhat dilated. The liver dulness began in the sixth intercostal space, and the lower edge of the liver could be felt five inches below the costal margin. There were three or four nodules which could be felt in this area moving on deep inspiration. Over the left orbit there was a swelling about the size of a large orange, which was roughly circular in outline and tailed outwards towards the ear, being in this region attached to the bone; it extended from just above the eyebrow down to the level of the nostrils, and from close to the middle line of the nose to a point four centimetres anterior to the external auditory meatus; the colour of the growth was bluish red; there were dilated veins in the surface, and also several white hard nodules, and at the inner part there was a shallow ulcer about two centimetres in diameter; no eyeball could be seen. The tumour could be moved slightly in all directions, and it was very massive and hard; the eyelids were widely stretched over it, the eyelashes being from 1 to 3 millimetres apart. The measurements of the swelling were: vertically 11.5 ccs., transversely 14 ccs., height from level of sound eye 3 ccs., vertical distance between the lids 6.5 ccs., distance between the inner and outer canthi 9 ccs. The pre-auricular gland and one behind the angle of the

jaw were enlarged and tender. There was a little paresis about the left side of the mouth and face. Owing to the character of the disease and to the probabilities of liver trouble existing also, there seemed no chance of any permanent benefit being derived from operative treatment; the patient, however, was a woman of extraordinary vitality, so Mr. Dodd determined to remove the growth as completely as possible in order to free her from her pains and from the discomfort of an ulcerating, discharging mass. Therefore, after she had been placed under chloroform an incision was made, beginning at the root of the nose and extending along the eyebrow close to the upper edge of the growth to about four centimetres beyond the orbital margin. The tumour was then raised from the bone as far as the edge of the orbit, and the incision continued round the lower margin

of the growth, at the level of the nostrils, and along the median side; the tumour was then separated from the bone to the lower margin of the orbit; owing to its remarkable solidity it was with some difficulty removed from the bony wall of the orbital cavity; it completely filled that cavity and was held very firmly down at the apex of the orbit, it being so hard and inelastic that it was practically impossible to get the finger between it and the bone to any extent. By means of a periosteal detacher, however, it was freed and the apical attachment divided with curved scissors. A second incision was now made from the first over the pre-auricular lymphatic gland which was then removed. No bone was taken away as the growth was considered too extensive. The edges of the wound were next brought together by sutures where it was possible to do so, and the orbital cavity was plugged and the whole exposed area dressed with cyanide gauze. The patient took the anæsthetic well, and at the end of the operation, which lasted thirty minutes, her pulse was good and she was warm. The growth removed weighed $7\frac{1}{2}$ ozs. Mr. Dodd said that

with regard to the glaucoma one fact had to be noticed which was interesting in the point of view of diagnosis: that the glaucoma was double, for it was usually laid down in text-books that in intra-ocular tumours the swelling will cause increasing tension in one eye, the other remaining normal. If the glaucoma this patient suffered from, he said, had any connection with the subsequent growth (which however, of course, it may not have had), then one point of assistance in the diagnosis of intra-ocular tumours was considerably weakened in importance. He pointed out that it was not to be wondered at that this old woman had suffered from such constant and severe pain when it was seen what an extraordinary amount of pressure the removed solid growth must have exerted on the walls of the orbit and on the surrounding structures. The conditions, he thought, somewhat resembled the inflammation in the hard structures of a tooth producing ordinary toothache. He also remarked that in removing a tumour or the whole contents of the orbit it would perhaps be found better to attack the growth from the outer side, as more freedom of movement is thus given through the extra space; but owing to the way in which this growth was fastened down at the apex of the orbit, there being absolutely no elasticity in the tumour, it was impossible to pull the optic nerve forward into the orbital cavity, as was usually advised to be done in all cases of malignant disease, so as to take away as much of the nerve as possible, and so lessen the chance of the future extension of the disease. In this case, however, this was not of so great importance, as it was not hoped to remove entirely all the disease.

On microscopical examination, the tumour was found to be a melanotic sarcoma, probably starting intra-ocularly and extending outwards and backwards along the optic nerve, it appeared as it were to roll forward all round the eyeball, and to enclose and to compress this, the globe being found in the interior of the growth.

Royal Institution of Great Britain.

THE lecture arrangements after Easter include the following:—Tuesdays, April 8th, 15th and 22nd, "On Recent Methods and Results in Biological Inquiry," by Allan Macfadyen, M.D., B.Sc., Jenner Institute of Preventive Medicine, Fullerton Professor of Physiology, R.I. The Tyndall Lectures, Tuesdays, May 20th, 27th, June 3rd, "On the Laws of Heredity, with Special Reference to Man," by Professor Karl Pearson, M.A., F.R.S. Thursdays, April 10th, 17th, 24th, "On the Oxygen Group of Elements," by Professor Dewar, M.A., LL.D., D.Sc., F.R.S., M.R.I., Fullerton Professor of Chemistry, R.I.

Gresham Lectures.

DR. E. STILES THOMPSON, Gresham Professor of Medicine, will deliver a course of Lectures in Gresham College (Basinghall Street, E.C.), on April 8th, 9th, 10th and 11th, at six o'clock each day, the subject being "Food and Diet." The lectures will be illustrated by diagrams, and are free to the public.

The Mortality in Foreign Cities.

ACCORDING to official returns supplied to the Registrar-General, the death-rate of the various populations per thousand for the latest week to hand was: In Calcutta 36, Bombay 109, Madras 48, Paris 23, Brussels 17, Amsterdam 19, Copenhagen 17, Stockholm 15, Christiana 12, St. Petersburg 23, Moscow 29, Hamburg 14, Munich 20, Vienna 21, Prague 24, Buda-Pesth 19, Trieste 25, Venice 23, New York 23, Philadelphia 22.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 6d. Post free, 8½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25 Os. 0d. Half Page, 23 10s. 0d., Quarter Page, 21 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 26, 1902.

THE MIDWIVES BILL.

THE passage of the Midwives Bill through the committee stage in Parliament without any substantial alteration in its provisions gives a fair index of the political influence of the profession. The Bill has been piloted by experienced Parliamentary hands, and there was an absence of organised opposition, which may perhaps be explained in part on the ground that, even in the ranks of the profession, opinions are divided as to the desirability of conferring a status on imperfectly trained women who practise midwifery for gain. The medical arguments against the Bill were no doubt weakened in some degree by the suspicion that they were aimed at the Bill less from the point of view of the safety of parturient women than from interested motives, a view which many of the speeches made at medical conferences must have encouraged. The control accorded to the General Medical Council is almost illusory. The attempt to substitute the Medical Council for the Privy Council as the body responsible for the formation of the Central Midwives Board failed, so that, as matters stand, proposed rules must be submitted by the Privy Council to the General Medical Council, whose recommendations must be "taken into consideration," but we all know what amount of consideration the Privy Council is in the habit of according to recommendations from this quarter. An amendment was agreed to requiring the midwife to give notice in each January of her intention to carry on practice, but although the principle is excellent it is not easy to see what good can result in view of the other clauses of the Bill. In future no unqualified midwife will be able to recover payment for her services, but an amendment imposing a penalty on unqualified persons for so practising was negatived. The penal clause thus applies only to the assumption of title, that is to say, the use of any title or

description implying that she "is a person specially qualified to practise midwifery." A further opportunity for moving amendments will, of course, occur when the Bill, as amended by the Standing Committee, comes before the whole House, a stage which, it is stated, is not likely to be reached until after the Whitsuntide recess. It was confidently anticipated by many that a Bill upon lines which had been in many respect formally disapproved by the General Medical Council would fail to receive the support of the House, but events have shown that the opinions of this body command scant respect in Government circles. This, we repeat, is an object lesson in medical politics and should impress upon members of the profession the importance of cultivating the arts of political influence. There is every prospect of the Bill becoming law much as it stands and the consequences, for good or evil, will have to be faced.

POST OFFICES AND THE SPREAD OF TUBERCULOSIS.

TUBERCULOSIS kills from 60,000 to 70,000 persons every year in Great Britain, this number being equal to about ten per cent. of the deaths from all causes. Tuberculosis is, indeed, the most deadly malady with which we have to contend. Public and professional attention has been aroused, and efforts to mitigate the evil are being strenuously carried on. Much interest is being given to the erection of sanatoria, and it is well, but sufficient importance is not laid on the measures which public bodies and private individuals are capable of initiating to secure the prevention of infection. There is little doubt that post offices as carried on in our crowded centres often offer facilities for the propagation of consumption, and attention has recently been directed to the frequency of phthisis among post-office officials. Mr. Garland, from statistics based on returns from reports of an insurance society confined entirely to post office employees, and the official returns of the Postmaster-General, shows that of every 100 deaths among sorting-clerks and telegraphists between the ages of fifteen and sixty-five years, 45·4 were due to phthisis. The loss from phthisis among workers in the Post Office is appreciably higher than that among the general populace, which stands at about 1·3 per 1,000 living. And yet it must be remembered that the Post Office staff consists of selected lives, candidates being required to pass a medical examination before they are admitted to the Service. We strongly contend that it is the duty of every department of the State to see that the health of our officials is not in any way impaired by the neglect of hygienic precautions or carelessness in respect of sanitary measures. In the present case we urge that it is necessary that the State should lead the way in the adoption of preventive measures, and so by force of example set a much needed lesson for other large employers. But not only are the great centres of the postal system in urgent need of reform but much remains to be done to make the local post offices more healthy for the members of the staff employed and less dangerous

to the public who have to frequent them. As everyone knows, the post offices in the metropolis and in many of our large towns often afford just those conditions which are particularly favourable to the spread of consumption. In this matter the Post Office authorities might set an example to shop keepers and small business houses. At present many a post office is little better than a death-trap for the young girls who serve therein, and the dust-laden atmosphere and filthy floors are real dangers to the public. Every public office directed by the State should be an object lesson in sanitary righteousness. It is but little good to build sanatoria for the infected if the State still perpetuates conditions which necessarily maintain a tuberculous environment. The sacrifice of life which is going on under evil conditions, capable of being readily rectified, is impairing the physical efficiency of the country, and it is time that the State shook itself free from the countenance of methods which are dangerous to the health of the Commonwealth.

THE TUBERCULOSIS PROBLEM IN THE UNITED STATES.

THERE can be little reasonable doubt that the extermination of that most disastrous scourge of humanity, tuberculosis, has now become simply a question of time. The rapid way in which medical science has reduced the malady from the position of an incurable and hopeless to a curable and preventable malady affords an admirable illustration of the boundless energy of modern scientific methods. In every progressive country of Europe the tuberculosis problem is engaging the combined attentions of philanthropists no less than of scientists and of sanitarians. The result is that popular opinion is being rapidly educated on all hands by the combined efforts of the Press and of the medical profession. In the United States the matter is being handled in the shrewd, practical, but, at times, short-sighted way characteristic of that country. An able article upon the tuberculosis problem in the United States, recently published in the *North American Review*, is worth studying from various points of view. The writer binges his remarks upon the recent declaration of the United States Government, through the Surgeon-General of the Marine Hospital Service, that pulmonary tuberculosis is a dangerous, contagious disease, and that all tuberculous immigrants and visitors must in future be barred from entering the ports of that country. Happily, in the light of our present knowledge, it is safe to assert that tuberculosis is not a dangerously contagious disease, but only a communicable one. Ordinary contact does not convey the disease as in the case of small-pox or scarlet fever. Therefore, concludes this outspoken critic, "to consider the careful, conscientious consumptive an individual afflicted with a dangerous, contagious disease is unscientific, unjust, and inhuman." Speaking generally, it may be said that the exclusion of consumptive aliens is probably just as sound or as unsound as the rejection of any other class of

immigrants. In the long run it will most likely be agreed by the majority of political economists that unrestricted immigration must result in the benefit of the country which admits that practice. The writer of the article under discussion maintains that it is right to exclude pauper immigrants, *qua* paupers, so that, from his point of view, there is no further need to consider the case of tuberculous pauper aliens. He objects to the new law, however, on the ground that it excludes well-to-do consumptives from the States. He pertinently asks whether such measures are not likely to lead to retaliation on the part of other Governments. The picture of wealthy American pulmonary invalids being rejected at various European health resorts is pathetic, but hardly likely, we should imagine, to be ever realised to any appreciable extent. If such a consummation were to be brought about, indeed, there would be no difficulty in developing many districts in the United States that would compare favourably with any in the whole world so far as the treatment of pulmonary consumption is concerned. The author sums up the consequences of the new regulation classifying tuberculosis among the dangerously contagious diseases. He says it has increased the dread of that malady to such an extent that healthy employees have been discharged because it had been reported they were living with consumptive relatives. Whole communities have refused to permit well-conducted sanatoria in their midst. This exaggerated swing of the pendulum Dr. S. A. Knopp, the writer, aptly calls "phthisiophobia." His contention is that the public want education, but that a great deal of harm will be done by frightening them by an over-statement of the case regarding the communicability of phthisis. He has not been content with abstract discussion and ascertaining and recording the opinion of eminent medical men in the States as to the new regulations dealing with the exclusion of tuberculous aliens. He has further presented to the New York Academy of Medicine a series of resolutions condemning the principle of the new departure root and branch. The learned body thus appealed to formally resolved that the Academy deeply deplored the State resolution to classify pulmonary tuberculosis with dangerous contagious diseases, as the step is not based either on clinical experience or on scientific experiments; secondly, that they consider the exclusion of non-pauper tuberculous immigrants and consumptive aliens visiting our shores unwise, inhumane, and contrary to the dictates of justice; thirdly, that while the Academy are convinced of the communicability of tuberculosis, and urges supervision of sputum and food, they are opposed to all measures whereby needless hardship is imposed upon the consumptive individual, his family, and his physician. The whole position in the United States is one of great interest to preventive medicine in all countries. There can be little doubt that the attempt to limit tuberculosis by the exclusion of infected aliens is a hasty an

ill-considered measure. In the United Kingdom it is to be hoped that the Government will not allow themselves to act on their own judgment in opposition to the views of medical men. At the same time it must be admitted that the position in our own country cannot be viewed altogether without apprehension, inasmuch as Mr. Balfour's Government have carried their vaccination and their midwives' legislation in the teeth of the protests of the medical profession. It is to be hoped, however, that tuberculosis legislation in our own country will be swayed by the cool judgment of scientific knowledge and not by the rash blunderings of ignorant and panic-stricken public administrators, who have one eye on office and the other on the electorate.

Notes on Current Topics.

Small-pox in London.

THE outbreak in the metropolis continues to increase in extent from week to week. Some six weeks ago we felt it our duty to forewarn the public that a serious epidemic might be expected. That view was not supported by our medical contemporaries, who solemnly maintained that the epidemic was well in hand, that there was no reason to apprehend its great extension, and that the state of affairs was not serious. Since that time the disease has been spreading by leaps and bounds, and the figures denoting notifications, deaths and patients under treatment in hospitals have steadily increased every week with one trifling partial exception early in the year. The attitude of the general press has also been in an unwarrantably optimistic vein. Last week one of the London dailies, writing of the Coronation, remarked that by then the small-pox would have been forgotten except by the families in which the disease had claimed a victim. That view is in our opinion most misleading and dangerous. The malady, if we mistake not, will go on spreading rapidly for several months to come, and with a possible diminution in the late summer, will probably last through the coming winter. One of the most notable events of the week in connection with small-pox has been the question asked of the Local Government Board in the Commons as to whether Dr. M. Copeman passed small-pox virus through monkeys and calves and then vaccinated children with the lymph thus obtained. This question was answered by Mr. Long to the effect that a number of children had been vaccinated under the conditions named, but not by Dr. Copeman. The vaccinations were not performed with the knowledge or sanction of the Local Government Board. In answer to another question Mr. Long pointed out that under Article 88 of the Education Board code the manager of any public elementary school might exclude unvaccinated children for a specified time. The fear of infection has prevented enthusiastic footballers from coming up to London to see the great game between Notts Forest and Southampton. There were only a hundred and sixty-four travel-

lers for the five special excursion trains provided by the railway company. A similar fear has already damaged London trade woefully and doubtless will keep many persons away from the Metropolis during the Coronation season. On Tuesday, the 18th inst., there were 52 fresh cases notified; on Wednesday, 19th, 71 fresh cases, and on Saturday, 22nd, 43 fresh cases, with a total number of cases under treatment in hospital at midnight on Saturday of 1,588. The new cases on Sunday amounted to 79 and on Monday to 65. Up to Saturday 5,267 cases had been treated, 725 by the Asylums Board, with 750 deaths; with 574 cases and 86 deaths from extra-metropolitan districts. On one night during the past fortnight there was the record number of 1,604 patients under treatment.

Varicose Veins.

THE etiology of varicose veins is involved in much obscurity. Taking the typical cases in which the disposition to varicosity appears early in life without any obvious cause, the condition is certainly one which suggests some constitutional cause as distinct from any local interference with circulation. In the Lettsomian Lectures of the Medical Society of London, Mr. Pearce Gould discussed the various theories which have been brought forward to explain this tendency, and concludes in favour of regarding varicose veins as due to venous hyperplasia—that is to say, venous angiomata—this conclusion being based on their irregular distribution and the distinctly hereditary character of varix. This view is corroborated by the surgical treatment of this affection, viz., ligature or excision, procedures which would obviously be inappropriate were the varicosity due to obstruction higher up, since the effect could only be to make matters worse. It must be remarked, moreover, that the usual symptoms of venous obstruction are usually absent in these cases, since an extreme degree of varix may exist for years without any obvious alteration of structure or impairment of function in the parts from which the varicose veins receive their blood. With regard to treatment, Mr. Gould favours the plan of ligating the great saphena vein in the upper part of the thigh, an operation associated with the name of Trendelenberg, a procedure which he has employed with marked success in a series of fifty cases.

Medical Men and Gifts from Patients.

A CASE of great importance to the medical profession has been recently decided in the law courts. The action was brought by the executors of an old lady of eighty to recover from a medical practitioner at Bromley £800. It appears that the money was given to him in four several sums, one of £500, and three of £100 each. The first gift was made in September, 1899, and the last a few days before her death, which took place on March 23, 1900. The executors brought no charge against the defendant of fraud or misrepresentation, or any direct or indirect misconduct in obtaining the money, but simply

that, having regard to his position as medical attendant upon the deceased, he was incapacitated from receiving or retaining gifts when the donor had no independent advice. Neither was it alleged that the deceased was not in a perfectly competent mental condition. The case was heard last week by Mr. Justice Swinford Eady in the Chancery Division. The Judge ruled in favour of the plaintiff, and said on the admitted facts the defendant must repay the whole of the money with interest. It seemed to his Lordship that it was of the greatest importance to give full force to the rule that forbade gifts from patients to medical attendants unless the donors had independent advice. A stay of execution was granted to allow an opportunity of appealing against this judgment. The application of a similar principle would render nugatory a great many gifts to churches, to charitable institutions, and to private individuals. Meanwhile, any medical men who are fortunate enough to meet with patients who are grateful as well as wealthy will do well to bear the above case in mind.

Damages for Medical Libel.

A CASE of considerable importance was tried at the Leeds Assizes last week, when Dr. A. S. Green, of that city, had to defend a claim for damages made against him by an ex-barmaid. Briefly stated, the circumstances were as follows:—Dr. Green was asked to examine the plaintiff in view of certain symptoms and partly as the result of his examination, and partly in consequence of an alleged admission by the plaintiff, he diagnosed pregnancy, a finding which he communicated to the housekeeper of the hotel where the plaintiff was barmaid. It was stated that he also made a similar communication to another barmaid, and the judge, in summing up, pointed out that although the communication to the housekeeper was privileged, no such immunity would apply to any information conveyed by the defendant to a fellow employee, a communication which, it is only fair to add, was formally denied by Dr. Green. It seems to have been admitted that the diagnosis was erroneous, although Dr. Green declined to modify his view in the absence of a further examination of the plaintiff, which was denied him. In the upshot the jury returned a verdict in favour of the plaintiff for £75. The case emphasises the duty incumbent upon every practitioner of observing the greatest circumspection with regard to communications concerning a patient, and any medical man who wantonly disseminates defamatory reports, be they true or otherwise, has only what he deserves when he finds himself mulcted in damages.

A Diet of Snails.

THE unequal distribution of wealth under modern social conditions calls into being many striking and extreme contrasts of wealth and poverty. Thus, on one hand we find the account of Royal Levées, where a single dress often represents the value of a King's ransom, at any rate what it would have been a few centuries ago. On the other hand we read of poor

folk in the provinces who are actually forced to eat snails for lack of other food. The extreme sharpness of the pressure is thereby proved forcibly, for the prejudice against an unaccustomed article of food is always of the strongest nature. As a matter of fact, snails are most wholesome and nutritious, and, as everyone knows, belong to the family of molluscs which furnishes oysters, clams, and other most savoury and highly esteemed details of the epicure's table. Very few Englishmen, however, eat snails by choice, any more than they would dine knowingly off horse cutlet or mule steak. The statement that the need of food has forced many poor persons to eat snails in the neighbourhood of Clifton was made by a clergyman last week at a meeting of the Church Pastoral Aid Society held in Bristol. It was there further stated that in Birmingham a worker was paid 7d. for sewing twenty-four gross of cards of hooks and eyes, while packets of hairpins were sewn upon cards at the rate of 4½d. a gross, ladies' aprons, neatly tucked, were paid for at 5d. a dozen, and children's pinafores, with lace insertion, at 9d. a dozen. This sweating, be it noted, takes place in prosperous Birmingham, which has netted enormous sums for war material during the last two and a-half years' South African War. These things lie at the root of the national health. It is little use providing good sanitation for populations who are sweated and starved.

The Etiology of Ranula.

It is, perhaps, not unreasonable to expect that the region of the neck, in view of the very remarkable developmental and morphological anatomy attaching to it, should provide a wide field for surprise, discovery, and ingenious scientific explanations. Still it would, perhaps, be premature to assert that nothing remains to be explained regarding neoplasms and tumours in this region, especially in reference to the origin of dermoid tumours. Unquestionably the condition commonly known as ranula must still be considered to be only partially understood. No doubt the attempt to assign a single cause to a number of similar conditions possesses a fascination for most minds, while others seem attracted rather by an attempt to multiply causes for not only similar but apparently identical conditions. The subject of ranula illustrates fairly well the effect of both these proclivities. It does not at present appear that it is possible to reduce the etiology of all cases of ranula to one cause, at the same time it is fairly safe to assume that some of the opinions once held on this subject may be disregarded. One of the more recent views appears to deserve particular attention: it is that ranula is a retention cyst of the sublingual gland or some portion of it. Much evidence may be brought forward in support of this theory, yet caution must be exercised in accepting it as the only explanation for all cases. Glands present great diversity of behaviour in their conduct when their ducts are obstructed; different results follow in different glands, and in similar

glands the results frequently depended chiefly on whether the obstruction be complete or incomplete, intermittent or continuous.

Cream of Tartar in Small-pox.

THERE is no more curious problem within the whole range of modern civilised man than his weakness for quack physic. In many instances the man in the street is ready to prescribe off-hand some pet remedy for this, that or the other malady, no matter how dangerous or hopeless the condition. The present London outbreak of small-pox has evoked a good deal of activity among this class of connoisseurs in patent medicines and cure-all remedies. One of the most emphatically vaunted cures for small-pox has been launched in the correspondence columns of the *Daily News*, in the shape of cream of tartar. The elixir, described not only as a remedy, but as a preventive for the disease, is taken in the liberal dose of three-quarters of an ounce dissolved in a pint of hot water, to which twelve grains of Turkey rhubarb are added. One correspondent, who claims this as a specific cure for small-pox, signs himself "Healthy, because Never Vaccinated," and thereby shows the depth of the reasoning powers which he brings to bear upon the action of cream of tartar in small-pox. He might just as well claim to have retained his health because he had never eaten roast beef and Yorkshire pudding, regardless of the fact that the majority of our robust countrymen have indulged freely in that national dish. Another sapient upholder of cream of tartar states that his grandfather, a "respected tradesman" of Dorking, administered that drug to over a thousand persons suffering from small-pox, with only one death, namely, that of a child. His son appears to have followed up this illegal medical practice, and to have extended it to the prevention as well as the cure of small-pox. Both these medical amateurs repeatedly memorialised Parliament to adopt their treatment, but their offers were declined. The Highgate Small-pox Hospital tried it in 1863, and reported unfavourably. In 1864 five cases of small-pox occurred in the "respected tradesman's" own household, and one of them was fatal. Notwithstanding this last blow the faith in cream of tartar as a specific for small-pox lingers in various parts of the United Kingdom. We pity the folly of those who take the responsibility of recommending treatment of the kind to other persons. It would be just as reasonable to fight the Boers with bows and arrows borrowed from the Tower of London.

THE Goldsmiths' Company have decided to contribute the sum of £5,000 towards the fund in support of the scheme formulated by the Royal Colleges of London for investigating the causes, prevention and treatment of cancer, and two other donations of like amount have been promised, one being by Mr. H. L. Bischoffsheim. An account for the "Cancer Research Fund" has been opened at the Marylebone branch of the London and Westminster Bank.

Medicine and the Collateral Sciences.

SINCE the opening of the twentieth century the benefits conferred on preventive medicine by the collateral sciences are such as are producing a silent, peaceful revolution on the earth. For untold ages the tropics, with their rich luxuriance of vegetation, have been shut to the Aryan, and held as the possession of the negro races, who were immune to malaria and yellow fever. As late as 1860 the British yielded the whole mosquito coast of Central America to the Republic of Nicaragua, as uninhabitable owing to the malaria and yellow fever. And it was principally owing to these diseases that Lesseps failed to complete his gigantic Darien Canal. To-day we are saying that the cause of all the loss of life and arrest of civilisation is due to *Culex anapholes*. Prior to the century the most advanced physician could add nothing to the old Italian theory of "bad air," which gave its name to the disease. A distinguished medical writer just before the opening of the century defines the disease as "an earth-born poison which is generated in soils the energies of which are not expanded in the growth and sustenance of healthy vegetation." All this unexhausted energy is the potential wealth of the rising generation which the labours of the entomologist, biologist, and physician give as a legacy, placing at their disposal the scientific knowledge that will enable them to dwell in the most fruitful regions of the earth, and in return bestow on them the higher civilisation of the Aryan.

The Coronation Procession and the Hospitals.

WE are glad to know that the hospitals on the line of route of the processions which are to mark the Coronation of King Edward are making arrangements to reap pecuniary benefit from their fortunate situation. It is said that St. George's Hospital hopes to obtain £7,000. Its commanding position makes it one of the most desirable points of vantage. The members of the staff, we understand, will be given a seat each for one day. Certain of the hospital wards are to be let for parties at something like 300 guineas. The King, in all his glory, will rejoice to know that the royal show will assist in relieving the wants of the sick and suffering.

Surgical Treatment in Thoracic Disease.

IT does not appear that certain forms of disease in the thoracic viscera can much longer successfully resist the attack by the surgeon. The measure of success which he has gained has been amply sufficient to encourage the hope that victory in this last stronghold of rebellious forces may be more frequently vouchsafed to him in the future. For too long has his assistance been sought by the majority of physicians only in cases of empyema; but now there is a suggestion, that whether encouragement is given him by the physician or not, the time has passed when he can afford to be even here but the physician's craftsman. The surgeon

will wisely never take the lead in the treatment of thoracic disease, but he must prepare himself to take the true position of a "consultant" in these cases, as he has educated himself to do in cerebral and abdominal cases. The future of lung surgery and the future of heart surgery are becoming every day more firmly established. The great obstacle to all advance—the doubt as to the possibility of success—has been overcome, and we may now look for steady progress in a direction where formerly advance was considered impossible.

The Dangers of Flannelette.

THE cheap, convenient and much-employed "flannelette" has long been recognised as a peculiarly dangerous cotton fabric. The warnings of coroners and juries have been conspicuous in our newspapers. And yet up to the present countless damage is caused to children by the use of this inflammable material, and many valuable lives are almost daily being sacrificed. Almost every medical man must have met with evidences of the danger of allowing flannelette to be used for the clothing of children. We have just received particulars from Cottonopolis that at last means have been found for rendering flannelettes non-ignifugous. Professor W. H. Perkins, Jun., the well-known chemist, working in conjunction with the large firm of manufacturers, Messrs. Whipp Brothers and Tod, has succeeded in rendering woven cotton non-inflammable. The great difficulty has been to retain the flannelette soft and warm according to its well-known and generally appreciated characters, and yet destroy all tendency to flashing on the approach of flame even after repeated washing. This, it is said, has now been accomplished, and we may hope soon to see a material which will be free from the dangerous characters for which flannelette has become notorious. We are glad to see that it is estimated that the preparation of non-ignifugous flannelette will probably not materially increase its cost, so that the new "non-flame" process bids fair to prove a great boon to child-life and a real blessing to poor parents.

Physostigma Faba.

PHYSOSTIGMINE, or eserine, holds its place in the Pharmacopœia by favour of the ophthalmologists, for it has almost disappeared from general practice. This may be credited to the tendency of the calabar bean to produce pain in the stomach, together with a sensation of oppression and weakness, and in toxic doses muscular relaxation, vomiting, and purging. The drug was sometimes used without due care, toxic symptoms were produced, it fell into disfavour, and a useful remedy in atony of the bladder and intestines and catarrh of the bowels was abandoned. Hare found it useful in gastric and intestinal dilatation, and it has proved useful in bronchial asthma. To-day it finds an advocate in Noorden (*Berl. Kl. Woch.*) in meteorism of the intestines due to atony. He has also prescribed it in cases of typhoid fever, and the atony that so often

follows on laparotomy. In cases in which it produces pain he adds a small quantity of atropine. The initial dose of eserine should not exceed 1-200th of a grain three times a day. It is best given in solution and may sometimes advantageously be combined with atropine. Where constipation is due to atony of the bowel, 1-150th to 1-100th of a grain with aloin and extract of nux vomica makes a good pill, one likely to restore the normal tone of the bowel, and dispense with the necessity for the constant use of the ordinary cathartics.

Intestinal Perforation.

THE difficulty of diagnosing intestinal perforation in cases of gun-shot wounds of the abdomen is of general recognition. If the bowel has escaped injury abdominal section may, in many cases, be avoided. On the other hand, if perforation has taken place, the sooner the lesion is found and operative measures for its repair taken the better. In doubtful cases Dr. Sutton, Peoria, recommends that the bowel be inflated by ether vapour. If the intestine be uninjured the gas makes its way into the stomach and eructations of ether, easily recognisable, occur. But if perforation has taken place the abdomen is quickly distended and the vapour of the ether is recognised as it escapes by the abdominal wound. Dr. Sutton has tested his theory by experience. In the case of a woman who was shot in the abdomen, the bullet passing above the liver, injuring the diaphragm and burying itself in the spinal tissues, ether gas, administered per anum, was quickly eructated by the mouth, demonstrating the absence of perforation of any portion of the intestine. The method is, however, open to objection; fecal obstruction in the lower bowel would very seriously interfere with its use, and injections to unload the bowel are not without risk in such cases. Besides this the vapour of ether thrown into the bowel causes severe pain in many individuals, and has produced tenesmus and even proctitis.

A Medical Legal Point.

APOPLEXY follows so soon after an injury that we are likely to forget that sometimes a considerable time elapses before it is manifest. Not so long since a prize-fighter in a contest received a blow on the skull of such violence that apoplexy and death resulted. But the apoplexy did not develop until some two hours after the blow had been given. A more marked case of deferred apoplexy is, however, that of M. Bemus, just published. A blacksmith, 41 years old, in good health, was struck on the head by a machine; he suffered a good deal from cephalalgia from the time he received the injury, and it increased in intensity until the fourth day, when he had an apoplectic seizure and died. On making the autopsy a large clot was found in the cerebrum, but the small vessels were quite free of sclerosis; the walls were quite healthy. The medico-legal importance of such a case cannot be over-estimated. Had that man met with the accident on a railway line or in a railway station and walked home his friends would have had

some difficulty in showing that apoplexy may not occur at the time of the accident, but may come on four days afterwards as the result of the injury.

The Royal College of Physicians of Ireland and the Midwives Bill.

WE laid before our readers in a recent issue our opinion on the Midwives Bill from an Irish standpoint, and dealt especially with the injustice which would be done to the great chartered midwifery hospitals of Ireland if their examination was not recognised as equivalent to the examination of the Central Midwives Board. We are accordingly pleased to learn that the Royal College of Physicians of Ireland decided, at a special meeting held on the 18th inst., to address a letter to the promoters of the Bill, the Clerk of the Privy Council, and the Irish members of Parliament, calling attention to the wrong which the passage of the Bill as it stands will inflict on the Rotunda and Coombe Hospitals. The Irish College has also drawn attention to what it considers to be the weak points of the Bill—points which almost exactly correspond to those about which we wrote previously. We are glad to find further that they have not called for the extension of the Bill to Ireland. During the passage of the former Midwives Bill through the Grand Committee the promoter, Mr. Heywood Johnstone, expressed his willingness to accept an amendment dealing with the recognition of the certificates of the Rotunda and Coombe Hospitals. There cannot be any difficulty which will prevent him from adopting a similar course on this occasion. In this connection, it is to be hoped that the authorities of the Rotunda and Coombe Hospitals are not losing sight of the important interests which it is their duty to protect, and that they are also laying their claims before members of Parliament.

Nativity in Great Britain.

MR. EDWIN CANNAN, in the current number of the *Fortnightly Review*, has an interesting article on the recent decline of natality in Great Britain. He endeavoured to show that the chance that persons reaching maturity will have children has been steadily diminishing since about 1884. There is some little alteration of this pessimistic view in the fact that the increase of population in the last decade of the nineteenth century was larger than that of the decade 1831-91. But if sufficient "sons of the Empire" are to be forthcoming, "paternity" must not become "a lost art." "Survival of the fit" is a means of securing a sound people, but "procreation of the fit" is a still more effective means of securing the best for the realm.

Colonel Trench and the Prevention of Consumption.

AT the third general meeting of the National Association for the Prevention of Consumption last week, Colonel le Poer Trench again trotted out his grievance in regard to the treatment for consumption invented by "a gentleman of the name of Alabone," his advocacy of which has not been

received in what he himself would consider a proper spirit. He announced that he would not relax his efforts to get Mr. Alabone reinstated in the membership of the Royal College of Surgeons, and he proposes to send copies of the documents to every working men's club in the kingdom, with what object is not quite obvious seeing that the influence of these bodies on the College cannot be very great. Sir William Broadbent, in moving a vote of thanks to Lord Derby, the chairman, briefly recapitulated the circumstances which had led to the removal of Mr. Alabone's name, adding that he had read his book and could not for the life of him make out what that treatment was.

Celibacy for the Consumptive.

MANY ethical considerations arise in regard to the care of the consumptive. Dr. Frederick Roberts, in his lectures at the Royal College of Physicians, has ridiculed the excessive anxiety of the public concerning the infectiousness of phthisis; and certainly the present attitude of the lay mind offers subject for grave thought. A writer in the current number of the *Saturday Review* now urges that legislation should forbid the marriage of tuberculous subjects, although he admits that "legislation is a drastic remedy [certainly a "remedy" it can hardly be], and one likely to be opposed by public opinion, but it is obviously more necessary now than ever." We are now to a great extent reversing Nature's methods. The individual, not the race, is the first care. The retention of numerous persons with tuberculous tendencies in our midst offers a problem in social life which it is difficult to solve. In regard to the question of marriage among those of phthisical tendency, the physician is often placed in a most difficult situation and asked to undertake a very delicate task; but in spite of recent optimistic views respecting the inheritance of tubercle and tendencies to transmit a liability to ready infection, there can be no doubt that marriage of the phthisical, or those with marked constitutional predisposition thereto, should be discouraged.

The X-rays in Medical Diagnosis.

UNTIL quite recently but a very limited use has been made of the X-rays as a help in medical diagnosis, although they have been largely availed of by both surgeons and dentists. This, no doubt, has been in a great measure due to the difficulty in getting good photographs of such organs as the heart and lungs, which are constantly in motion. This has, in a great measure, been got over by means of the graphic method described by Mr. Haughton in a communication to the last meeting of the medical section of the Royal Academy of Medicine which appears in another column of our present issue. The restricted movements of the diaphragm, and the opacities in the lungs which can be demonstrated even in the very earliest cases of phthisical consolidation, are most interesting and instructive. We have no doubt that there is a very wide field of usefulness for the rays in this department of medical

diagnosis, and one, too, which will be largely developed in the near future.

An Anti-everything Journal.

THAT section of society so unhappily constituted as to be in chronic rebellion against everything established or rational has at length secured for itself a special publication. That important fact has been duly announced by *American Medicine*, a journal that furnishes a happy illustration of the resolve of American medical men to purify their scientific literature of all the degrading associations of trade and of ignorance and quackery in its myriad forms. The editor of the orthodox journal furnishes some facts about *Our Home Rights*, as the organ of universal rebellion is named, which reads like a description of American humour run riot in a mad-house. There are to be twenty-nine departments, so it seems, each under a sub-editor, and described as "Depts." Among the depts. are the following Socialistic, Philosophic Anarchy, Vegetarianism, Anti-War, Medical Freedom, Therapeutic Suggestion, Single Tax, Astrology, Botanic Medicine, Individual Opinion, Sex Ethics, Dumb Animals, Economic and Political Salvation, and lastly—ye gods!—the Cranky Notions Dept. It would be interesting to glance through the advertisement pages of this weird journal, for therein would certainly almost be found the key to the new venture. When reduced to simple terms it seems to be an invariable rule that the wire-pullers of any particular faddism go to work upon strictly commercial lines.

The Physical Features of Britain.

AT a time when attention is being drawn to the beneficial results of treating phthisical cases by "open-air" methods in our own country, it is well that the climatic conditions and physical features of our land should be more closely studied with a view to the ascertaining of the precise factors which assist physiological processes in the healthy or tend to arrest pathological states in those who have fallen from man's bright and natural estate. We therefore commend Mr. H. J. Mackinder's very valuable study of "Britain and the British Seas," which has just been issued by Mr. William Heinemann.

Alcoholism among Women.

MR. RITCHIE, in explanation of the proposed legislative restriction of "off-licenses," has stated that drunkenness among women had increased, and in fifteen years the number of deaths from intemperance in women had doubled. He showed that there had been a great multiplication during recent years of the facilities for drinking, and that the demand for legislation went far beyond and covered a wider area than so-called temperance organisations. If Mr. Ritchie were only able to consult His Majesty's medical advisers, or would appeal to the experience of the leaders of the profession, or, for the matter of that, to the rank and file of medical practitioners, he would quickly find that the danger he is seeking to lessen is very real

and demands immediate attention. The alcoholisation of large numbers of women is becoming a danger to the State and goes far to account for much of the physical inefficiency of large numbers of the uprising generation.

The Extermination of Infected Animals.

THE inhabitants of Plymouth, U.S.A., have been having a lively time of it of late in consequence of a campaign undertaken by the Board of Health for the extermination of stray dogs and cats, which are suspected to be the means of disseminating small-pox and other infectious diseases. In the abstract the campaign must command approbation, but for parties of volunteers to march through the town armed with shot guns for the purpose of destroying stray animals is a proceeding which has its drawbacks, in that the wandering and homeless animals were not the only recipients of the leaden shower, sundry wandering inhabitants having received a share, as well as some who merely looked out to see what was going on.

Syphilis among the Moors.

MR. BUDGETT MEAKIN in his new work on "The Moors," devotes a chapter to "matters medical," in which he says the national disease of Morocco is syphilis, called the "great sickness," or "women's sickness." It is surmised that "every other man, woman or child is tainted with this disease in one form or another." Apparently no effectual treatment is adopted in the majority of cases.

THE Second International Congress for the Prophylaxis of Syphilis and other Venereal Diseases will be held at Brussels from September 1st to 6th, 1902. Details can be obtained from the Hon. Secretary, Mr. J. Ernest Lane.

PERSONAL.

DR. JAMES HARPER has been created an Esquire of the Order of the Hospital of St. John of Jerusalem in England.

MR. HENRY N. CUSTANCE has resigned the post of secretary to the Metropolitan Hospital Sunday Fund owing to ill health. Mr. Custance had held this appointment since 1873.

THE PRINCE AND PRINCESS OF WALES visited the Hospital for Sick Children, Great Ormond Street, on Saturday last, and expressed on leaving the pleasure derived from their visit.

AMONG the recipients of honorary degree at Owens College, last week, was Sir Thomas Barlow, Bart., K.C.V.O., M.D., F.R.C.P., who was admitted to the degree of Doctor of Science.

DR. JASPER A. ANDERSON, formerly of Blackpool, has been appointed on the Royal Commission to inquire into and report upon the water question and the general question of self-government in Cape Colony.

FRAULEIN DR. LEA ROLAND has been nominated for the post of Assistant to the Chair of Children's Diseases

in the University of Budapest, this being the first occasion on which a lady has been appointed to a university post in Hungary.

DR. KERR, on the occasion of his resigning the post of Medical Officer to the Bradford School Board, has been presented with a rosewood clock by the office staff in testimony of the amicable relations that have existed throughout between them.

At a Convocation of Durham University, held last week, Sir George Hare Philipson, M.D., D.C.L., was appointed to represent the University in the General Council of Medical Education and Registration of the United Kingdom for the term of five years.

THE Royal College of Surgeons in Ireland has decided to confer the Honorary Fellowship on Captain Crean, V.C., in recognition of his distinguished services in South Africa. Captain Crean is a licentiate of the College, having obtained his diploma in 1895. Since the institution of the reward for "conspicuous valour in the presence of the enemy" five Irish surgeons have been awarded the Victoria Cross. Of these, one belongs to the University of Dublin; the other four are diplomates of the Royal Colleges.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE PROFESSION AND THE PUBLIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In my last letter published in your issue of March 12th I wrote of the effect of the anti-vivisection and anti-vaccination propagandism in producing disbelief in medical science, and distrust and suspicion of medical men, and in driving large numbers of the simple public into the hands of unqualified, cruel, and infamous quacks. I further pointed out that many editors and contributors, as well as proprietors of papers also, take their stand on an anti-scientific platform, and no doubt have more faith in the blatant pretenders, from whose advertisements they derive so large a share of their incomes, than in even the most accomplished and honourable members of a highly educated profession. I did not imagine that my statements would so soon once again be fully and forcibly illustrated; but nothing more *a propos* or more interesting could have followed my letter than the correspondence which, during the past fortnight, has been going on in *The Times* under the heading "Anti-vivisection Methods." The correspondence from the anti-vivisection side has been largely made up of shameful aspersions upon the profession, and foul and cruel libels upon individuals engaged in physiological research. The falsehoods have been exposed by Mr. Victor Horsley, Dr. Grunbaum, and others; but the complete failure of any amount of proof to shake the faith of the fanatic has been, as usual, fully exemplified. The Hon. Stephen Coleridge has, of course, been to the fore; and although Dr. Grunbaum showed that the latest pamphlet of horrors, issued by the Anti-Vivisection Society, was crammed full of errors and misstatements, the Dowager Lady Portsmouth wrote to say that she looks upon Mr. Coleridge as her ideal knight, who wields only "the bright sword of perfect accuracy." This lady is worth quoting only as a type of the amiable women who, in proportion as they are respected for their personal goodness are powerful to influence their unreasoning fellows and win recruits to the fanatical army.

With reference to the effect of the anti-vaccination propaganda in the direction I am dealing with, I think nothing more forcible could be said than is conveyed

by the report of a meeting published in *The Times* of this morning, March 19th. General Phelps, Mr. T. Bayley, M.P., and Mr. C. H. Hopwood, K.C., all believe in the shocking imputation upon our profession put forth by the chairman, and endorsed and accepted by the meeting—a meeting of a kind which could no doubt be repeated in every division of the metropolis, and in every great town throughout the kingdom.

In previous letters I have sufficiently dwelt upon the significance and importance of the facts I have adduced, I need not take up your space further by any reiteration.

I am, Sir, yours truly,
UBIQUE.

ANTI-VACCINATION DEMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It seems to me little short of criminal for a man of education and presumably of intelligence—I am referring to one Lieut.-General Phelps—to go about the country making absolutely mendacious statements against vaccination, statements which the poor and uneducated are unable to appreciate at their proper value. At a recent meeting at Mile End, for instance, this strange person committed himself to the assertion that "the first person to take small-pox was invariably the person who had been vaccinated." These are the men who do so much mischief in stirring up the populace against this beneficent and innocent operation, and unfortunately it is not easy to devise a means of making them "eat their words."

I am, Sir, yours truly,
MILE ENDER.

THE OPEN-AIR TREATMENT OF PHTHISIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the letter which you kindly inserted for me a month ago, in which I claimed priority in the open-air treatment of phthisis for the Dublin and Belfast schools, I regret that incomplete knowledge of the history of the subject caused me to do an injustice to an able English writer on the subject, namely Dr. Boddington, who published a very able book dealing with this question as far back as 1840. This has now been republished by the Sydenham Society. I was partly led into the oversight by the absence of any reference to early English pioneers of the open-air system in Dr. Vinrace's handbook to the Congress on Tuberculosis, the reading of which gave rise to my letter. It seems to me that this useful book would be improved by a fuller account of the past history of the disease and the genesis of the present rational mode of treatment.

I am, Sir, yours truly,
JAMES HAMILTON, M.D., Q.U.I.
60, Sydney Street, Chelsea, S.W., March 21st, 1901.

SHOULD THE ARM BE BANDAGED AFTER EXCISION OF THE BREAST?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—This question admits of a very decided answer in the negative. I shall be glad to be assured that the practice of fixing the arm is not so common as your note on this subject implies. When I began to remove breasts I followed the universal custom of including the lower arm and forearm in the bandage to keep the limb still. The invariable result was a stiff and useless arm for weeks and weeks. Somewhere between fifteen and twenty years ago I began to leave the arm free, merely supported on a pillow, even when the axilla had to be cleared out, and the nurse was instructed to alter the position of the forearm from time to time. Since then I have never seen a stiff arm, and as a rule the patient has the free use of her arm as soon as the wound is well healed, and is encouraged to use it. It has seemed to me a strange thing that the idea had not occurred sooner to others.

There is another aspect of the question of bandaging to which I may take the opportunity of calling attention. As far as I can learn it appears to be the common practice to use the roller bandage to support the dress-

ings. For at least twenty years I have discarded it in favour of the many-tailed bandage. This form involves no more disturbance of the patient than the moving of the arm from the side just enough to allow the dressings to be changed. My bandage is made in this way. Take three strips of stout gauze (such as used to be employed in making the carbolised or thymolised gauze, but without these agents) forty-five to fifty inches long, and five inches wide; lay two of these strips side by side and place the third half over each (this makes a bandage ten inches wide); then lightly stitch a double piece of the same gauze or a single piece of linen or cotton ten inches long and six inches wide across the middle of the bandage, and add two shoulder-straps. These are brought over the shoulders after the bandage has been applied, and fastened in front. The advantages of this bandage are inestimable. It can be applied with the greatest accuracy and it is cool for the patient, while the convenience of the surgeon and, what is more, the comfort of the patient are both consulted.

I am, Sir, yours truly,

GEO. GRANVILLE BANTOCK.

12, Granville Place, March 22nd, 1902.

Literature.

TEXT-BOOK OF PHARMACOLOGY AND THERAPEUTICS. (a)

This is practically a system of pharmacology and therapeutics, the contributors being all well-known authorities in this department. This method, although it has its drawbacks, ensures a certain freshness of treatment which, on the whole, compensates to some extent for the absence of a more definite scheme of classification. One's ideal of a work of this kind is a full and complete account of the action and properties of the drugs and agents of which it treats, and it seems an unnecessary tax on the reader's attention to insist upon his taking cognisance of statements concerning particular drugs which have been disproved, or at any rate have not been confirmed, by subsequent experience. We require to know what a drug does, not what it fails to do.

The opening chapter on the relation between chemical constitution and physiological action, by Professor Haldane, deals very fully with this interesting and, in his hands, comprehensive subject. We have as yet but attained to the fringe of this line of investigation, and much remains to be done before it will be possible to forecast with even approximate accuracy the physiological action of a given compound on the strength of its chemical composition. The author possesses a singularly lucid style which materially assists the reader in following what are, at times, very complicated series of inferences and deductions. In the chapter on the action of gases a very full account is given of the action of oxygen gas, and this is interesting in view of the popularity which the administration of this gas has attained of late, a popularity which would not appear to be justified by the net results except in a very limited class of cases.

One turns with curiosity to the chapter on anaesthetics, by Drs. Rose Bradford and Leonard Hill, and it is with a feeling little short of dismay that we find it stated that chloroform is best administered "from a Skinner's mask or other single layer of porous material," the safest limit of chloroform vapour being put at 4 per cent. How the anaesthetist is to secure this or any other limit by pouring chloroform on to a mask the authors do not say; indeed, it is impossible, and in any event experience has shown that 4 per cent. of chloroform vapour is an unnecessarily large proportion, one, too, which may conceivably be dangerous in certain cases. To give full directions for administering chloroform with barely an allusion to such a thing as a regulating inhaler constitutes an omission difficult to understand and still more difficult to justify. A reference is made, it is true, to the employment of Junker's

inhaler in mouth and nose operations, but recourse thereto is deprecated "especially in the strong!" Mention is made of the possibility of pumping the liquid chloroform through the efferent valve and thence into the air passages, apparently in ignorance of the fact that for several years past this accident has been rendered impossible by the introduction of a glass bulb filled with absorbent cotton into the efferent tube. We only hope that this chapter does not represent the teaching in the metropolitan schools of medicine, other than University College. It would have been well to warn anaesthetists, especially the inexperienced, against the unpleasant consequences of giving chloroform in the vicinity of gas flames, when the decomposition of the chloroform gives rise to a most irritating compound.

In the chapter on cardio-vascular tonics, the composition of digitalis strikes one as incomplete, no mention being made of the crystallised digitaline, discovered by Nativelle and now so largely employed, an omission of importance, since all the glucosides vary greatly in physiological activity owing to their variability of composition. In his remarks on Ergot, Dr. Rose Bradford states that the efficacy of the drug as an abortifacient is "doubtful," a view which has been advanced on various occasions in opposition to that of a certain well-known toxicologist. In regard to the action of morphine, again, no mention is made of the fact that its ingestion determines an increase in the secretion of hydrochloric acid, a circumstance which it is important to bear in mind when tempted to prescribe it in ulcerated conditions of the gastric mucous membrane. Under the head of antiseptics, Dr. C. R. Marshall gives a qualified approval to the use of boric acid as a preservative for milk, adding, however, that "the question is primarily one of dose." The only argument advanced in favour of its use for the purpose is that it delays souring and enables the milk to be given in a comparatively fresh condition throughout the day. But there are other, and in every respect preferable, ways of preserving milk for infant consumption without making use of a substance which is admittedly an extremely feeble antiseptic, and which, in the long run, is apt to determine more or less troublesome gastric and cutaneous affections.

The chapter on organotherapy by Dr. Hector Mackenzie is a careful synopsis of this recent development of therapeutics, and leaves nothing to be desired. Similar commendation may be extended to the chapter on serumtherapy, by Dr. Washbourn, though much of the information is essentially provisional, and will soon require revision in the light of further development.

The work may fairly be accorded a foremost position among treatises on therapeutics. It is clearly printed, and a copious index facilitates reference.

FAGGE'S TEXT-BOOK OF MEDICINE. (a)

We welcome the appearance of a fourth edition of this magisterial treatise which it may safely be affirmed, will more than maintain the reputation of its predecessors. In this edition there is much less of Dr. Fagge and very much more of Dr. Pye-Smith, a change which cannot but be a source of satisfaction in view of the immense change which has come over our views and the numerous additions to our knowledge, since the regretted original author laid down his pen.

The more important chapters commence with a brief historical sketch, followed by the clinical symptoms and course of the disease, the diagnosis, ætiology, and, lastly, the treatment. The personal element in this work confers upon it a special charm. We feel we are listening to a man who has carefully pondered views on the subject of which he is treating. While he by no means fails to credit others with their original work, his manner of discussing their results shows clearly what degree of importance he attaches thereto, and we are never left to wallow in the slough of divergent and often contradictory opinions. To the student—and who among us is not a student—this method of treatment presents unquestionable advantages.

(a) "A Text-book of Medicine." By the late Charles Hilton Fagge, M.D., F.R.C.P., and P. H. Pye-Smith, M.D., F.R.S., F.R.C.P., Consulting Physician to Guy's Hospital. 4th Edition. Vol. I. London: J. and A. Churchill 1901.

(a) "Text-Book of Pharmacology and Therapeutics." Edited by W. Hale White, M.D., F.R.C.P., Physician to and Lecturer on Medicine at Guy's Hospital. Edinburgh: Young J. Pentland. 1901.

tages. We do not require to be told that which is not but rather that which is, and without being unduly dogmatic Dr. Pye-Smith succeeds in conveying the impression that he is an excellent clinical teacher as well as an observant and experienced physician.

We share the author's regret that considerations of space prevent more attention being devoted to the historical aspects of certain conditions of disease. Such knowledge has a great educational value, it assists us in understanding the evolution of the natural process, and is, moreover, an object lesson in the means whereby we may succeed in casting additional light on the obscure problems which hem in the pursuit of medical knowledge.

The directions for treatment are ideally brief and practical. No treatment is mentioned unless experience has shown that it can be recommended, and the whole scheme for dealing with each particular disease is compressed into a few terse sentences. We commend the author's remarks on the treatment of diphtheria and hydrophobia to our readers' attention in illustration of what we have just said.

The subsections of chapters and the dependent paragraphs are set out with headlines which greatly facilitate research, and serve to map out the various aspects of the disease.

We are unable, after diligent search, to point to any errors of omission or commission. The work has been brought well up to date, that date being 1900 at any rate, possibly later. An unusual feature is the poetical quotation which heads each chapter, most of them being remarkably apposite and even illustrative, witness the quotation from Dryden, who associates quinsy with rheumatism, thus forestalling modern pathologists, who are beginning to suspect that the relationship may possibly be of cause and effect.

We are promised the second volume very shortly, and the complete work will constitute an invaluable addition to every medical library. The print is rather small for a book over which hours will have to be spent in the attitude of study, and its clearness is not always all that could be desired, but the latter may be a blemish peculiar to the copy before us.

BALLANCE AND STEWART ON THE HEALING OF NERVES. (a)

THIS able monograph is a welcome contribution to medical literature. It will not only prove of much service to those engaged in clinical work but be of deep interest to students busy in the unravelling of some of the problems in neuro-pathology.

The exact process whereby peripheral nerves after division may become reunited has long been a subject of controversy. The research, of which this volume is the record, was undertaken with the object of solving some of the enigmas with regard to the processes of degeneration and regeneration in divided nerves. Most of the work was completed by the end of 1899, but the absence of Dr. Purves Stewart in South Africa has delayed its publication. The investigation has necessitated much experimental work and extensive microscopic research. No less than 140 observations are recorded in detail.

The work deals with such points as: The process of degeneration in a peripheral nerve after injury; with and without immediate suturing of the proximal to the distal segment. The process of regeneration in a nerve-trunk which has been divided and subsequently reunited by suture. The process of regeneration in the distal segment of a nerve-trunk which has been divided, but in which the proximal and distal segments have not been brought into apposition. The changes which occur in nerve-grafts. The animals selected for constant observation were monkeys, dogs and cats, and a number of specimens were obtained from

the human subject during operations for the relief of injuries to various nerves. The specimens were stained according to the methods of Weigert, Cox's modification of Golgi, Stroebe, and Van Gieson.

The particulars of the various observations are excellently presented, and the reproductions of Mr. Lapidge's very beautiful drawings are admirable.

The conclusions reached are of great importance. Much diversity of opinion has long existed as to the exact manner in which regeneration is accomplished in a divided nerve. Most authorities have supported the "central" view, according to which it is maintained that the new axis cylinders are direct outgrowths from those in the central segment, the young axis-cylinders sprouting downwards and worming their way into the empty neurilemma sheaths of the distal segment and replacing the old axis-cylinders, which had previously become degenerated and been supported. But the authors unhesitatingly declare their adherence to the "peripheral" view, according to which the new fibres in the distal segment—axis-cylinders, medullary sheath and neurilemma alike—are formed from pre-existing cells in the distal segment itself. The young axis-cylinders and medullary sheaths, so it is shown, are laid down in the first instance in the distal segment and they become attached later to those of the central segment, thereby restoring the conductivity of the nerve trunk. The bearing of all this on clinical work will be sufficiently apparent. But Dr. Purves Stewart and Mr. Ballance show also that the results of their observations go far in throwing doubt on the correctness of the now widely accepted and generally taught neurone theory. If their observations and conclusions be correct, and there are no good grounds for refusing to accept them, then there seems to be no escape from the dogmatic expression of their view that "the neurone theory, in so far, at least, as it applies to the peripheral nervous system, must, in our opinion, be discarded."

The work is in every way one of importance. Both in design and execution it is deserving of high praise. It should do much to stimulate and encourage scientific research into the problems which daily face the neurologist. The bibliographical references should prove of service.

HALLIBURTON ON THE ESSENTIALS OF CHEMICAL PHYSIOLOGY. (a)

IN spite of every endeavour to keep the dimensions of this excellent guide to Chemical Physiology within moderate compass, some increase in size has been found necessary. The principal additions in this, the fourth edition, are chapters relating to the chemistry of various tissues, of the purine compounds and the important subject of osmosis. Additional space is also devoted to the phenomena of polarised light, a matter of investigation which yields results as remarkable in this connection as in spectral analysis. This work might well serve as a model to writers of books for students. The author's style is brief, but extremely lucid; there is hardly a superfluous word, and the text is illustrated by a large number of figures of instruments, &c. An unusually copious index completes the attractions of a work which certainly need fear no rival.

PSYCHOLOGY, NORMAL AND MORBID. (b)

DR. MERCIER is a man already known to us as an author of many excellent works, and it is with a feeling of agreeable anticipation that we turn to a perusal of another volume from his pen. "In his 'Psychology, Normal and Morbid,' we are not disappointed. He here points out the importance (in insanity) of a knowledge of the normal as an indispensable preliminary to a knowledge of the abnormal, and he gives guidance to the alienist in the face of problems which are of pro-

found importance to him. The volume is divided into the following sections, viz., sensation, thought, volition, memory, pleasure and pain, and subject-consciousness. To the two sections, sensation and thought, he devotes two-fifths of the book, and under volition he discusses effort, will and desire, free will or choice and character, and then goes on to deal with the faults of volition, attention, effort, instinctive determination, and acquired determination. He has treated at considerable length the section under the heading of subject-consciousness, and has disengaged the various meanings of the term "self." Disorder of the subject-consciousness is also dealt with, and the disorders of the personality are to some extent elucidated, but space does not permit of us discussing each section in detail. There is so much in this work that is original, and so much that affords food for reflection that we can cordially recommend its careful study to all alienists.

SANATORIUM TREATMENT. (a)

THIS pamphlet, very neatly and even elegantly got up, and adorned with numerous pleasing illustrations, is an extension of a paper read by the author at the meeting of the British Medical Association, at Ipswich, in 1900.

A better situation for a sanatorium and open-air treatment could hardly be found than that afforded by St. Lawrence, Isle of Wight. The elevation is 350 ft. above the sea, the soil dry and porous, while hills and pine forests keep off the rigour of the winter winds.

As to results of treatment, we learn that out of twenty-two patients five entirely recovered. No physical signs could be detected, nor tubercle bacilli in the sputum, when thus left. A summary is given in brief of the kind of case not likely to benefit in the Sanatorium—or, indeed, anywhere, we feel disposed to say.

Of the value of drugs, such as creosote, guaiacal, &c., the author has a poor opinion. The inhalation of formalin has given very encouraging results, however. Very wisely is it said, on page 23, prognosis depends much on the state of the stomach. Open air and generous living go well hand in hand to help the consumptive one into health, and these are the conditions under which life is carried on at Inglewood Sanatorium.

OSLER'S PRACTICE OF MEDICINE. (b)

THE appearance of a fourth edition of this most popular American work will be welcome to a large circle of readers on this side of the Atlantic. The present edition has been marked by various important changes; for example, the "typhoid" fever article has been in great part rewritten, and other sections generally brought up to date, with the addition of many new articles on fibrinous bronchitis, adiposis dolorosa, myasthenia gravis, and so on. The article on "typhoid"—to give it the old name—is, on the whole, the best with which we are acquainted. After giving the facts of the agglutination test as a datum for diagnosis the author adds, "While on the whole the serum reaction is of very great value, there are certain difficulties and objections which must be considered. A perfectly characteristic case with hemorrhages, rose spots, &c., may give no reaction throughout. In other cases the reaction is much delayed, becoming positive only during convalescence, or even during a relapse." The appearance of the sign "&c." in the middle of a serious composition, by the way, reminds us that the author's style, although on the whole charming, is nevertheless not absolutely free from blemishes. The use of the word "humbury" (p. 417) in another place affords another instance of the kind. The article on splenic anemia makes no mention of Banti, who first described the affection in 1882. Dr. Murrell and others in this country have recently called attention to the value of

surgical operation to establish anastomosis, and so relieve the cirrhotic liver that characterises these cases. The article on gout is luminous and interesting. Of piperazine it is very properly remarked that the clinical results are "discordant." Sufficient prominence is not given to the "superheated air" treatment of this malady, which originated in England some years ago, and in our opinion forms one of the most valuable advances ever made in the treatment of chronic and irregular gout. The great value of this book lies in its clearness and conciseness. The author knows how to present essentials in a pleasant practical way. His well deserved success is testified sufficiently by the rapid sale of large editions of his work on both sides of the Atlantic. Edinburgh may well be proud of her distinguished graduate.

Lunacy Department.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH ROYAL ASYLUM.

TO Dr. Clouston's annual report we always turn with interest and eager anticipation, as he has the happy method of serving up facts, even if not new, in a fresh and attractive manner. The outstanding features of his report for the past year are the continued overcrowding of the wards and the admission of a large number of general paralytics. These features must be regarded as indicating a serious state of affairs, and towards rectifying the former the District Board, if they have the best interests of their patients, as also that of the rate-payers, at heart, would lay down their individual differences regarding the new asylum they propose to erect at Bangour. There is scarcely any accommodation available for the admission of the very people for whose benefit the asylum was primarily and mainly designed, a hardship unnecessarily inflicted. As to the latter and very sad feature, Edinburgh should take stringent measures to eliminate the generally accepted cause, which eateth like a canker, of this interesting but terrible and fatal brain disease. Worry, one of the classical three we've never appears to us very conspicuous from casual observation in our modern Athens, compared with other large commercial cities in Scotland. Between one-third and one-fourth of the admissions suffered from general paralysis, and, as compared with the average rate of prevalence of organic brain diseases sent to the Scottish asylums, this asylum had to deal with about double the number. In referring to the effects of city life, Dr. Clouston says: "A death-rate from that one disease among the asylum population, twice as large as the death-rate from all causes in the city of Edinburgh, is an impressive fact, and a very suggestive commentary as to the effects of city life, and its accompaniments on certain human brains. The contrast which the 'Blue-book' enables us to make in regard to that disease between Edinburgh, Glasgow, Aberdeen, and Dundee, and the rural districts, throws a lurid light on some of the dangers of city life. In rural district asylums the proportion of deaths from general paralysis was only 5.1 per 1,000 residents, as compared with 22.6 in the four large cities, and 29.2 in the Edinburgh Royal Asylum. To understand the meaning of these figures one must know that general paralysis practically means certain forms of immorality. I am surprised at the apparent greater prevalence of the disease in Edinburgh as compared with other Scotch towns, and I cannot explain it. It is the most typical disease of the actual mind machinery in the brain that we know of, and it should be regarded by society as a special kind of danger signal. It attacked the male sex chiefly, and at the prime of life, and they were not the weaklings and the worthless whom it killed, but more commonly the most active and energetic."

The report includes statements by Dr. John MacPherson and Dr. John Fraser, Commissioners in Lunacy, as to their inspection of the institution, the former alluding to the pressure created by the excessive number of

(a) "Some Results of Sanatorium Treatment of Phthisis." By D. J. Chowny-Muthu, M.D., &c., Physician, Inglewood Sanatorium, &c. London: John Bale, Sons, and Danielsson, Ltd. 1901.

(b) "The Practice of Medicine." By William Osler, M.D. Edin., Professor of Medicine in the Johns Hopkins University and Hospital, Baltimore &c. Separate editions have been issued in Great Britain: in London by Mr. Hy. Kimpton, and in Edinburgh by Mr. J. T. Pentland.

patients sent to the asylum by the city parochial authorities, and stating that unless the District Lunacy Board can provide accommodation for some of their patients at an early date, either at Bangour or elsewhere, it is impossible to see how serious overcrowding can be averted. In the West House the overcrowding of the wards had been the worst prominent feature of the year, and Craig House has been so full that admission had sometimes to be refused.

An interesting portion of Dr. Clouston's report is the part referring to two remarkable inmates of outstanding position and long residence, who displayed faculties of no mean order, and who died during the year. The one is described as "a poet, an inventor, and a wit," and the other as "a devourer of books," of whom the tradition is that he had read through the "Encyclopædia Britannica" and had survived. In concluding his report he observes, "The new proposal to establish a mental ward in the Royal Infirmary for incipient, transient cases of mental disorder, if established on right lines and properly worked, would be most philanthropic and useful," and this opinion we quite endorse.

INVERNESS DISTRICT ASYLUM.

THIS report for year ending May 15th, 1901, has only now reached us. During the year 151 patients were admitted, 87 discharged, and 34 died, leaving 614 patients on the Register. The ages of the admissions varied from 15 to 80 years. Eight were under 20 and 9 were over 70 years of age. Four patients died within 48 hours after admission, and 6 died within a week. Such cases are aggravating, and it is questionable if they should be sent to an asylum. The causes of insanity show that hereditary influences and alcoholic excess were responsible for 48 and 18 of the 151 cases admitted respectively. The recovery rate is high—49 per cent. on the admissions, and the death-rate—5·8 per cent.—is a low one. Phthisis was the cause of death in 8 instances, or 24 per cent. The question of accommodation in this Asylum imperatively calls for serious and immediate consideration. There is accommodation for 540 patients, and at date of the report it provides breathing space for 599 patients, or 50 more than the specified number. But there are in the Asylum 80 or 90 suitable cases for boarding out, and it is to be hoped the Parish Councils will co-operate with the asylum authorities in procuring fitting homes for them, and arranging their removal without undue delay. The overcrowded condition would be relieved thereby, and it would also give the Board ample time to go fully into the question of extensions, and what form they should take. It should be borne in mind that it will take at least two years to provide additional buildings. The dining-hall is overcrowded to the extent of at least 150 patients. This is a great source of regret, as it must cause much discomfort to the patients, and increased noise and excitement during the meals. However, plans for two small dining-halls, each to dine 100 patients, have been approved of by the Board, and it is expected building operations will be commenced at an early date. There has been no outbreak of infectious disease, and the year passed without the occurrence of any serious accident. The nurses have got comfortable accommodation in the new home, and we learn with approval the District Board have passed the plans of five cottages for attendants, and a house for the steward. The alterations and extensions at the laundry are nearing completion. We are glad to see that the absence of any means of heating the corridors and dormitories in the main building is being rectified by extending the system of heating by hot water pipes and radiators, which has been found so satisfactory in the newer hospital extensions. The renovation and refitting of the lavatories, which has been in progress for several years, one or two lavatories being undertaken at a time, is now approaching completion. A piggy and slaughterhouse have been erected. In the table showing the occupations of the admissions, nine women are described as "housewives" and one as the "wife of shoemaker." Is she not a housewife too? Why then, this and like definitions? The Commissioner reports the accommodation for sick,

recent and acute cases, will compare favourably with that of any other asylum in the kingdom, and that the asylum throughout was found in very good order.

Medical News.

Irish Medical Schools' and Graduates' Association.

THE annual general meeting of the above association was held on March 17th (St. Patrick's Day) at the Hotel Cecil, London, when the outgoing president, Dr. William Alexander (Liverpool) resigned the chair to Sir Philip C. Smyly (Dublin). There was a very large attendance of members, and it was announced that the society now numbers 821 members. A vote of condolence with the relatives of the late Sir William MacCormac, a foundation member and former president of the association, was passed. Later in the day the festival dinner of the association took place at the Hotel Cecil, with Sir Philip Smyly in the chair. There was an unusually large number of members and ladies present. In proposing the loyal toasts, the chairman said that they as Irishmen were expecting a visit from his Majesty the King, but unhappily to the heart of every Irishman that visit had been put off. He felt sure they would all join with him in the earnest hope that the postponement might only be of very short date. The Arnott memorial medal, which is given by Mr. David Arnott annually in memory of his late father, the late Sir J. Arnott, to a graduate of an Irish University or the holder of a diploma of an Irish corporation for "an act of heroism or distinguished service or act performed in the discharge of medical duties either in civil life or in naval or military services at home, on the high seas, or abroad," was then presented by the chairman to Dr. Brendan MacCarthy, who, in conjunction with Dr. W. Smyth, who succumbed to the contagion, removed certain typhus patients in a small boat from an island off the coast of Ireland to the mainland. Dr. St. Lawrence Finny (Mayor of Kingston-on-Thames) proposed "Our Defenders," and Dr. Gilbert-Smith proposed "The Guests." Lord Rathmore, in responding to the latter toast, after returning thanks, congratulated the Association on their great success. It was, as he understood it, a society for mutual comfort and support in the marauding expeditions in which they were usually engaged, a successful association of eminent Irish poachers on the well-stocked preserves of the English medical profession. He wished they could tempt a greater number of Englishmen to go to Ireland. He believed it was in common interests and in community of daily life between the two peoples in every walk of life, in everything that would bring Irishmen to know, appreciate, and understand Englishmen, and Englishmen to know and understand Irishmen—it was in that direction that they would soonest find a safe and sure solution of that Irish difficulty which had so long baffled the wisdom of statesmen. He looked forward to the day when his countrymen would be completely and for ever blended with their Irish and Scotch brethren, content to live together in the enjoyment of all the common benefits and interests, and all the glories of that mighty empire which their race had done so much to build up and maintain. Miss Kate Rooney's singing was much admired, and Surgeon-Major Marshall's songs were enthusiastically received.

General Medical Council Finances.

FROM the return of the accounts of the General Medical Council just laid before Parliament it appears that the receipts for the year ended December 31st, 1901, amounted to £8,023 3s. 3d. The total of the General Council's special receipts, which embraced the sale of publications, the fees for registering foreign and colonial medical qualifications, and rent from freehold property, is represented by £457 14s. 1d. The amounts to be contributed by branch councils are as follows:—England, £4 250 8s. 7d.; Scotland, £2,594 17s. 11d.; Ireland £730 2s. 8d. The expenditure side of the account shows that a sum of £3,315 17s. 1d. was spent in fees and other expenses in connection with the General Council, the executive committee, and various other committees,

including the fees of an expert employed by the education committee. The cost of printing was £1,243 13s. 8d. A grant of £500 was made to the Irish branch council, while a sum of £215 13s. 6d. was credited to the sinking fund for the extinction of the mortgage created in accordance with the General Council's resolution of June 8th, 1899. The excess of expenditure over income continues and for last year it amounted to £1,509. The account of the receipts and expenditure of the dental registration fund of the General Medical Council shows an income of £1,059 0s. 6d., as against an outlay of £693 14s. 9d.. The surplus carried forward, therefore, in this special connection was £365 5s. 9d.

Vaccination Items.

AN appeal is made for public support on behalf of 160 cigar makers who have been locked out by Messrs. Salmon and Gluckstein because they refused to be revaccinated. Of all the reasons for a lock-out, which in this instance is only another name for a strike, this is, perhaps, the most extraordinary. In this connection it is interesting to note that during the week ending the 15th inst. no less than 22,262 cases of small-pox were reported to have occurred in the United States, a fact which shows how widespread is the epidemic there.

A Medical Man Pays Damages for Libel.

DR. CHARLES FREDERICK SIXSMITH, of Barry, was the defendant in an action for libel tried at the Glamorgan Assize, a few days ago. The circumstances were somewhat peculiar. A patient of the defendant's, the subject of tuberculosis, received a blow in a club squabble and died three months later, and it was alleged that Dr. Sixsmith, in alluding to the affair, described it as "a brutal murder." The claim was made by the man who had struck the blow, and who was therefore implicated by the remark. Judging from the evidence the injury received had nothing to do with the death, and Dr. Sixsmith's attitude in the witness box was, to put it mildly, ambiguous. Ultimately the jury returned a verdict in favour of the plaintiff for £10 by way of damages.

Anderson Fund.

LORD STAMFORD and his Committee request us to state that this fund is now closed.

The following is the full and final list of subscribers, and makes up the total amount received as certified:—

	£	s.	d.
1. Total of list published July 31st, 1901	52	10	0
2. " " Oct. 30th, 1901	24	3	0
3. " " Feb. 26th, 1902	78	13	6
4. Total amount collected by Dr. Cox representing the "General Practitioner"	88	13	6

Total amount already published	244	0	0

Further list:—Dr. Frank, Elvaston Place, £3 3s.; Dr. Shelmerdine, Bexley Heath, 10s. 6d.; Dr. J. O. Brookhouse, Nottingham, 10s. 6d.; Anon, 10s. 6d.; Dr. L. Lewis, 6s.; Dr. G. B. Robatham, Monmouth, £1 1s.; Dr. H. Stear, Saffron Walden, £1 1s.; Dr. E. Elliott, Tunbridge Wells, £1 1s.; Dr. Cropley, Northampton, £1 1s. Dr. G. Evans Franklin, Cardiff, £1 1s.; Dr. Q. Priestly, Halifax, £1 1s.; Dr. B. Baskett, Leeds, £1 1s.; Dr. C. H. Taylor, Derby, £1 1s.; Dr. H. L. Smith, Ballytrophy, £1 1s.; Dr. G. C. Franklin, Leicester, 10s.; Dr. T. C. Beatty, Clackton-on-Sea, 10s.; Dr. Emmett, Portsmouth, £1 1s.; Dr. J. Thomason, Bowes Park, £1 1s.—Total, £17 10s. 6d.

Total amount received as certified, £259 7s. 6d.

THE Household servants of Queen Victoria, to the number of 600, have subscribed to endow a bed in perpetuity in Clewer Convalescent Hospital as a memorial of their late Royal mistresses. Her Majesty maintained a bed in the institution at her own expense, to which, by her desire, invalid soldiers had the first claim. The King has continued the late Queen's patronage and subscription.

Dublin Death-rate.

THE deaths registered in the Dublin area for the week ending Saturday, March 15th, represent a mortality of 21·2 in every 1,000 of the population. Tuberculous disease caused 23 deaths; diseases of the respiratory system caused 41 deaths; diseases of the circulatory system caused 17 deaths; 37 infants died during the week, of whom 21 were under 1 year; and 8 deaths were "uncertified," there having been no medical attendant during the last illness. The death-rate in the following districts of the city proper were as follows:—Black Hall Place, 32·9 per 1,000; Peter Street, 28·7 per 1,000; Grand Canal Street, 28·4 per 1,000.

Royal Victoria Hospital, Belfast.

AT the annual meeting, on the 18th inst., of the governors of this institution the report stated that the number of in-patients treated in the hospital during the year was 2,080; convalescent home, 354; consumptive department, 29; children's hospital, 137; total, 2,600; in addition to which 25,453 patients were treated in the extern department, and, as the average attendance of extern patients is about three times each, shows a total estimated attendance of 76,359, being an average daily attendance of 209. Dr. Calwell, staff physician, and Professor Sinclair and Dr. Kirk, staff surgeons, having retired by rotation, were unanimously re-elected. Drs. Malcolm Brice Smyth and Radcliffe were appointed house surgeons instead of Drs. Rice and Byers, whose term of office had expired, and Drs. McCrea and Weir in place of Drs. Rankin and Logan, resigned. In thanking the medical and surgical staff for their successful treatment of the patients, the board placed on record its regret of the recent death of Sir William MacCormac, Bart, who was connected with it for so many years. The report then dealt with the financial condition of the hospital which appears to be in a satisfactory condition.

THE Lancashire and Cheshire Branch of the British Medical Association recently passed a resolution to the effect:—"That, in the opinion of this Council, seeing that vaccination is made compulsory, in the interests of the public health, the parent or guardian of a child should have the right to select any registered medical practitioner, who is willing to do so, to perform the vaccination, and that the cost of the same should be defrayed by the State at a fixed rate, provided always that the work so done shall reach the standard aimed at by the Local Government Board in the case of public vaccinators, and that no work falling short of this standard should be accepted for the purpose of public remuneration."

Pass Lists.

Society of Apothecaries of London.

THE following candidates have passed during the month in:—

Surgery.—C. R. Bradley (Section I.); S. J. H. M. Eastwick Field; J. W. Elliott (Section I.); H. S. French (Sections I. and II.); K. Heanley (Section I.); E. O. Libbey; S. C. Wilkinson (Sections I. and II.).

Medicine.—F. G. Bennett (Section II.); W. T. Colyer; H. S. French (Sections I. and II.); R. Gauld (Sections I. and II.); K. Heanley (Section I.); W. St. A. F. Hubbard (Sections I. and II.); O. Millauro (Section I.); H. H. Sloane (Section II.); W. P. Taylor; J. E. Turle (Section I.); A. F. Van Dijk (Sections I. and II.).

Forensic Medicine.—H. S. French, W. St. A. F. Hubbard, W. P. Taylor, J. E. Turle, A. F. Van Dijk, J. H. Williams.

Midwifery.—D. Cotes-Predy, G. M. Crockett, E. F. Forjett, H. S. French, H. M. Jones, J. A. Kilpatrick, M. E. Martin, H. H. Sloane, G. B. S. Soper, S. Zweiback.

The L.S.A. diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—W. T. Colyer, S. J. H. M. Eastwick Field, H. S. French, E. O. Libbey, S. C. Wilkinson, and J. H. Williams.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

FRAUDS ON MEDICAL MEN.

MR. T. SNEYOUR TUXE, M.B., Oxon., writes us in reference to the "caution" that appeared in our columns of March 12th, that the man "Dr. Perry" called on him at 30, Queen Anne Street, W., on January 15th and previous dates, but did not succeed in extracting coins, though he did try it on under the same specious excuse he gave to Dr. Japp Sinclair, of Manchester. Mr. Tuxe adds that he will willingly give evidence if the man is arrested.

T. E. B. (Liverpool).—We are unable to give the reference asked for, the writer of the article not being accessible. The subject was probably dealt with in the American journals of a few weeks since.

ENQUIRER. The season has already commenced at Aix-les-Bains, and we understand the leading hotel have received a number of visitors the past fortnight. The reading rooms at the Casino Cercle open on April 1st, and the music commences in the Grand Cercle on April 15th. Many visitors are expected at Aix-les-Bains during May and early June, on their route (from the United States, Egypt, Sicily, Italy, the Riviera, Tyrol and Italian lakes) to the Coronation.

ACUTE URTICARIA.

A CORRESPONDENT writes to ask what is the best local application to allay the distressing irritation of this condition. He will find a host of remedies vaunted for the purpose. Perhaps the most satisfactory, on the whole, is alcohol, which should be dabbed lightly on the skin, not rubbed, and allowed to evaporate. Eau de Cologne answers the same purpose. Vinegar and water sponging is sometimes useful, or rubbing with a slice of lemon. A dilute nitric acid has been recommended, and carbolic oil is said to be effective. The fact of the matter is that both external and internal remedies are legion in urticaria, and that fact alone points to their dubious success as routine remedies.

QUEERNS.—The association of a medical man with a trading company dealing in medicinal wares, although it would not bring him under the notice of the General Medical Council, would assuredly be regarded as indecorous and undesirable by public opinion, unless, indeed, he abandoned the practice of his profession.

M.P.C.—It is not usual for the sanitary authority to communicate directly with the certifying practitioner in the event of an erroneous diagnosis under the Notification Act. The practitioner may be trusted to receive due intimation of his mistake from unofficial sources. Moreover, it is always open to him to make direct inquiry of the medical officer to the hospital.

SUPERFLUOUS HAIRS.

THE evidence of the value of the Bontgen ray method of depilation of superfluous hairs on the face is conflicting. Some few operators claim that in the long run they can permanently destroy the growth. At the best, however, the process takes many months—often a year or more—and is tedious, costly and dangerous, not to mention the fact that it may ultimately fail. The only scientific method of destruction of such hairs is by electrolysis. The operation should be placed in the hands of a medical man. It is a thousand pities that medical practitioners should advise their patients to go to non-qualified persons for Bontgen-ray photographs, electrolysis and other ministrations that are obviously medical in their nature.

DR. CARPENTER and DR. FOWLER's communications are unavoidably held over on account of great pressure on our space.

MR. CLEMENT SERS.—We think it wise under the circumstances to let the matter rest. The facts of the case were known to the public through the newspapers and the sentence was generally considered a mild one after the fatal result.

LEINSTER LEADER.—Your repudiation shall appear in the next "Poor-law Supplement," as desired.

DR. W. (Hordey).—Your patient is entitled to demand details of his account, with each item priced, and it is always undesirable to appear to grudge this concession. The practice of sending in "total" bills is based on courtesy.

THE MEDICAL PSYCHOLOGICAL ASSOCIATION.

THE next Examination for the Certificate in Nursing and Attending on the Insane will be held on Monday, May 5th. Candidates should obtain from the Registrar (Dr. Alfred Miller, Hatton Asylum, near Warwick), a schedule, to be filled up, signed, and returned to him at least four weeks before the date fixed for the examination. Monday, April 7th, will be the last day upon which, according to the rules, candidates can enter their names for the May examination.

MESO.—We do not care to publish mere "notes" of cases of observations of the sexual sense. These vary *ad infinitum* and possess no

individual interest although the psychical problems underlying these disordered manifestations deserve, and are receiving, attention.

Appointments.

BAIGENT, W., M.D.Durh., Medical Officer of Health for North-allerton.
BEEGLING, D. H., B.A.Syd.Univ., M.B., C.M.Edin., Medical Officer to the Post-office at Huddersfield.
BRISCOE, WILLIAM THOMAS, M.D.Dub., M.Ch., Medical Officer of Health to the Chippenham Corporation.
CHERRSWRIGHT, J. F., L.R.C.P.Edin., M.R.C.S., Medical Officer of Health to the Greasborough Urban District Council.
CHUISS, RICHARD E., M.R.C.S.Eng., L.R.C.P.Lond., House Surgeon to the Bristol Eye Hospital.
FINLAY, G. B., M.B.Aber., Medical Officer of Health for Brailes.
GAYLOR, E., L.R.C.P.Edin., L.F.P.S.Glas., Medical Officer for Alfreton Rural District.
GRIFFIN, IZES, M.R.C.S.Eng., Medical Officer of Health for Banbury.
JONES, HELENA G., M.B.Lond., Assistant Medical Officer, District Asylum, Mullingar.
JUDSON, J. E., M.R.C.S.Eng., L.R.C.P.Lond., late Senior Resident Medical Officer of the Manchester Workhouse, Crumpsall, House Surgeon to the District Infirmary, Ashton-under-Lyme.
MARTIN, J. MIDDLETON, M.B., B.C., D.P.H.Lamb., Medical Officer of Health for the Stroud Urban District Council.
NETTLE, WILLIAM, M.R.C.S., L.S.A., J.P., Medical Officer of Health for Lisakeel (Cornwall).
PALMER, A. M., M.R.C.S., L.R.C.P.Edin., Medical Officer of Health for the Urban District of Whittington.
PHILLIPS, HUBERT C., M.R.C.S.Eng., M.A.L.S.A., Anaesthetist to the Female Lock Hospital, Harrow Road, London.
STARKIE, E. G. B., M.B., C.M.Edin., Medical Officer of Health for Poulton-le-Fylde.
SOLTAU, GRACE, L.R.C.P.&S.Edin., House Surgeon, Belgrave Hospital for Children, London.

Vacancies.

Bedford County Hospital.—Senior House Surgeon. Salary £100 a year, with apartments, board, and washing. Applications to the Secretary.
Brentford Union.—Assistant Medical Superintendent. Salary £120 per annum, with furnished apartments in the Infirmary, rations, washing, &c. Application to William Stephens, Clerk to the Guardians, Union Offices, Isleworth, W.
Carlton Union.—Fever Hospital Nurse. Salary £30 per annum, with rations and apartments. Applications to John George Glover, Clerk. (See Advt.)
Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, with board, furnished apartments, &c. Applications immediately to the Medical Superintendent.
Durham County Hospital.—House Surgeon. Salary £100, with board and lodging. Applications to Wm. E. Wilson, Secretary, 684, Saddler Street, Durham.
Folkestone Victoria Hospital.—House Surgeon. Salary £100 per annum, with board, residence and laundry. Applications to the Secretary.
Galway Hospital. Resident Medical Officer and Compounder of Medicine. Salary £75 per annum, with rations and apartments. Applications to S. J. Leonard, Clerk. (See Advt.)
Manchester Royal Infirmary.—Honorary Assistant Physician. Applications, with diplomas, original testimonials, and certificate of age, to be sent to the Secretary (See Advt.)
Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160 per annum, furnished apartments, attendance, light and fuel are found. Applications to Secretary, M. I. Preston, Journal Chambers, Nottingham.
Omagh District Asylum.—Assistant Medical Officer. Salary £100 per annum, with £50 in lieu of rations, &c. Applications, with copies of testimonials and certificate of age, to the Resident Medical Superintendent (See Advt.)
Richmond, Whitworth and Hardwicke Hospitals, Dublin.—Assistant Physician for a period of three years. Applications before April 7th to the Secretary. (See Advt.)
Royal University of Ireland.—Examiners in Surgery, Midwifery, Pathology, and Ophthalmology. Applications to the Secretaries not later than April 19th. (See Advt.)
Southampton Incorporation. Resident Assistant Medical Officer. Salary £100 per annum, with apartments, rations, washing and attendance. Applications to David P. G. Willim, Clerk to the Guardians, Clerk's Offices, Workhouse, Southampton.
Tunbridge Wells General Hospital.—House Surgeon. Salary £100 per annum, together with board, furnished apartments in the hospital, gas, firing, and attendance. Applications to the Assistant Secretary, at the General Hospital.

Births.

HUDSON.—On March 21st, at Buntingford, the wife of F. Horace Hudson, M.R.C.S., L.R.C.P., of a son.
HUNNARD.—On March 18th, at Mansfield, Notts., the wife of Arthur Hunnard, M.B., B.S.Lond., prematurely, of a daughter.

Marriage.

WEGG—BROG.—On March 18th, at Christ Church, Mayfair, London, William Henry Jervis Wegg, eldest son of the late W. Wegg, Esq., M.D., to Winifred, second daughter of Henry M. Biss, Esq., of East Lodge, Bexhill.

Original Communications.

VARIETIES OF NERVE-DEAFNESS. (a)

By DR. DUNDAS GRANT, F.R.C.S.,

Surgeon to Central London Throat and Ear Hospital, London.

If we may judge by recent otological literature the general tendency has been to confine attention exclusively to the surgical treatment of suppurative disease of the middle ear and petrous bone in relation to their dangerous sequelæ. Consideration seems to have been almost entirely withdrawn from diseases of the ear as an organ of hearing.

This is not altogether surprising when we remember how much can be done in the former direction, still less so when we realise how many of the latter class of diseases are not susceptible of successful treatment. The feeling has, however, gone too far, and the diseases in question have lacked the careful study they deserve. While admitting that the proportion of incurable cases is considerable, I am convinced that in many the effect of treatment has been marred by erroneous diagnosis. I have detected this as made by myself as well as by others. I do not refer here simply to obscure cases in which certainty of diagnosis is scarcely attainable, but fairly ordinary cases in which more detailed examination leaves little room for doubt. It is only right to remember that in investigations in which the tests are so largely subjective the patient's faulty observation and inaccurate evidence are often largely responsible for the erroneous decision.

By nerve-deafness I mean dulness of hearing produced by disease of the auditory nerve, its nuclei, the cortical centres or the strands connecting them.

The auditory tract commences in the hairs of the auditory nerve-cells, and continues through the spiral ganglion, the cochlear nerve (in the internal auditory meatus and the cranial cavity), the accessory auditory nucleus, the trapesoid body, a tract parallel with the lateral fillet, the internal geniculate body, the subthalamie portion of the tegmentum cruris, the internal capsule, and the corona radiata, to the cortical centre in the superior temporo-sphenoidal convolution.

The pathological possibilities are obviously extremely numerous, and some extremely obscure. I shall only refer to a few of them.

I shall not take up your time in reviewing in detail the *uning fork tests*, as to the value of which we are fairly agreed; I shall, however, make the reservation that I assume that the evidences they afford are reasonably well marked, and that we interpret their results with a careful regard to their recognised limitations.

Diminished bone-conduction, negative Weber and positive Rinne, when met with in association, afford the typical, unquestionable evidence of uncomplicated nerve-deafness, if the dulness of hearing is at all marked.

When nerve-deafness accompanies middle-ear disease Rinne is negative, Weber may be positive, and we may

have to depend on diminution of bone-conduction, or, I believe, absence of the increase of bone-conduction, which should accompany pure obstructive disease.

In simple unilateral nerve-deafness we may have a negative Rinne, because in the test the air-conduction of the affected ear is compared with the bone-conduction of the sound one. The result may be checked by means of Weber's test, which would be "negative," and is therefore, in unilateral cases, extremely valuable. I leave you to judge of the signs obtainable when there is obstructive deafness on one side and nerve-deafness on the other.

A "positive" Rinne does not, however, exclude a minor degree of obstructive deafness, unless the time during which the given fork is heard at the meatus after ceasing to be heard on the bone is the same as it is in the normal individual.

It is to be noted that if a very high-toned fork is employed it is impossible to prevent it being heard through the air by the opposite ear if the latter is normal (or even affected with obstructive disease), even though this is stopped by any means available, and air-conduction appears longer than it really is.

The same is true with regard to the high-pitched tones of Galton's whistle, and therefore, to make sure that it is actually the affected ear—and not the sound one—we are testing, we stop up the diseased ear as well, and note whether the sound ceases to be heard; then we open the ear again and note whether the sound is again audible. This is the check devised by Dennert.

Again, with a low-toned fork, which is necessarily massive, the patient is apt to mistake the mechanical vibration excited by the instrument for acoustic stimuli, and an apparent increase of bone-conduction is produced. A fork of about 250 vibrations per second should, therefore, be used, and preferably one which in the normal individual is heard for about fifteen seconds through the air after ceasing to be heard through the bone.

There is one test which deserves more credit than it generally receives, namely, Gallé's centripetal pressure. In carrying out this test a vibrating tuning-fork is placed on the vertex, while the tip of a Politzer bag is in the auditory meatus. When the bag is compressed the sound should instantly decrease to a very marked extent if the stapes is mobile, because this bone is driven in so as to exercise pressure on the labyrinthine contents. Should this decrease not take place the stapes is assumed to be ankylosed. In the former case Gallé's test is "positive," in the latter "negative." It is obvious that if the membrane is extremely relaxed or if it is largely destroyed the pressure cannot be so effectively exercised, and its results are, in such circumstances, of little value. The cases in which it is of special value are those in which there is, with a practically normal membrane, a high degree of deafness, and the diagnosis lies between ankylosis of the stapes and nerve-deafness.

Having diagnosed the existence of nerve-deafness as such, we have to decide on the *site and the nature of the lesion* on which it depends.

In regard to the site we have to depend on the information afforded by the state of the neighbouring nerves and other parts of the nervous system, and also by the

(a) Opening Paper of a Discussion on "Varieties of Nerve Deafness," British Laryngological, Rhinological, and Otological Association, March 14th, 1902.

determination of the part of the acoustic scale for which the hearing is most defective. The nature of the lesion is chiefly revealed by its mode of onset and course, and by the associated symptoms of disease of the system in general or other organ in particular.

Sudden onset is characteristic of hæmorrhage, embolism, or nervous shock.

Rapid onset, with pyrexial disturbance, indicates acute inflammation. Without inflammatory disturbance a rapid onset is very characteristic of syphilitic disease of the labyrinth.

A *gradually developed nerve-deafness* results generally from degenerative, chronic inflammatory, or slow nutritive changes, or from the formation of a new growth.

The methodical examination of the *cranial nerves* from before backwards would be the proper step for the clinical student, but we may for practical purposes save time by taking them in the following order: facial, vago-accessory, hypoglossal, sixth, and continuing forwards to the first.

In all cases in which nerve-deafness is diagnosed or suspected the hearing for the highest-pitched tones should be tested by means of Galton's whistle or Koenig's steel rods. The former is probably sufficient for clinical purposes.

It may be taken as a general rule that in a case of nerve-deafness as detected by means of the tuning-fork, if the loss of hearing is specially marked for the highest tones, the disturbance is most probably situated in the labyrinth; if not, it is probably in some other part of the central auditory tract, and in many cases is functional. The check referred to in connection with high-pitched tuning-forks is equally important in testing with Galton's whistle.

Should no obvious lesion of other nerves (we shall consider the vestibular nerve as being part of the auditory) or the *general nervous system be present*, we are guided by the results of testing the range of hearing, and if hearing is most impaired for the highest tones we may very safely assume that the lesion is in the labyrinth.

Should hearing not be mainly defective for the highest tones, then the lesion is situated most probably in some other part of the auditory tract, such as the cortical centre, and is often functional in nature.

Facial paralysis alone, conjoined with nerve-deafness, is in suppurative cases usually due to tuberculosis of the petrous bone, while without suppuration it is more likely to arise from a lesion in the internal auditory meatus.

Involvement of the vago-accessory, as evidenced by paralysis of the corresponding half of the palate and of the vocal cord of the same side, indicates a lesion deeper than the internal meatus—say, a gummatous pachymeningitis on the under surface of the medulla. The same is true of the hypoglossal nerve.

Paralysis of the trunk of the sixth occurs in basic meningitis, involving it in its long exposed course on the under surface of the pons, characterised by paralysis of the external rectus of the corresponding eye. When with it the internal rectus of the opposite eye is affected, the lesion is situated in the nucleus.

Anæsthesia of one-half of the face alone would indicate a local lesion of the sensory nucleus of the fifth, but as found in association with nerve-deafness it is usually combined with hemianæsthesia of the side of the body, for special as well as general sensation.

Regarding involvement of the central nervous system in general the following points: Cross-paralysis, hemiplegia, hemianæsthesia, "word-deafness," ataxy, optic neuritis, ophthalmoplegia.

Cross-paralysis indicates a lesion in the pons below the decussation of the facial tracts. Hemiplegia points to the opposite hemisphere, probably the internal capsule; hemianæsthesia may arise from disease of the sensory tract in the posterior part of the internal capsule, or else from an affection of the cortical or subcortical sensory areas, generally hysterical. In the former case there is loss of the corresponding halves of the fields of vision of both eyes; in the latter there may be loss of acuteness in the whole of the field of vision of the opposite eye (crossed amblyopia), coupled sometimes

with colour-blindness in that eye (achromatopsia or dyschromatopsia). This is well shown in the case reported below.

I have already referred to the partial ophthalmoplegia arising from disease of the sixth nucleus—namely, paralysis of the external rectus of the same and internal rectus of the opposite eye. Complete ophthalmoplegia would point to disease in the nuclei and longitudinal bundle in the tegmentum below the level of the aqueduct of Sylvius—apt to be encroached upon by tumours of the quadrigeminal bodies.

Testing the vision and determining the fields of vision is of importance in connection with hemianæsthesia.

The ophthalmoscope should be in frequent requisition, though it is only very rarely that in our practice it reveals positive pathological changes. The existence of optic neuritis or choked disc should obviously not be overlooked. The following case was only elucidated by my finding very typical albuminuric retinitis, my observation being confirmed by the expert to whom I referred the case:—

Mr. P—, æt. 53, was referred to me by Dr. Lauchlan on account of deafness and singing noise in the right ear; this was of three weeks' duration; he had suffered from vertigo and vomiting; the tuning-fork evidences were those of nerve-deafness. Galton was not heard above the 5.5, as checked by Dennert's method; the ophthalmoscope revealed well-marked albuminuric retinitis, and there was a scarcely detectable trace of albumin in the urine.

The patellar tendon reflex or knee-jerk gives us often important information, its loss suggesting locomotor ataxy or post-diphtherial paralysis, its exaggeration, apart from other serious evidences, pointing to heightened nervous excitability, as in neurasthenic conditions.

Disturbance of equilibrium, taking the form of definite vertigo, is in by far the largest number of cases due to aural lesion, and when this is associated with nerve-deafness the loss of hearing for the highest tones usually locates the lesion as in the labyrinth. Rarely, however, disease of the cerebellum or the peduncles may produce definite rotation. In cerebellar disease there is usually staggering like a drunken man if the middle lobe is affected; paresis of the upper extremity of the same side if a lateral lobe, even if the characteristic vomiting and optic neuritis are not yet *en évidence*.

The *nature of the lesion* is, as I have already stated, mainly indicated by the mode of onset and the course. I shall refer to a few types.

Suddenness of onset generally indicates a hæmorrhagic effusion into the labyrinth, rarely an embolism, not very unfrequently a sudden nervous shock. Hæmorrhage into the labyrinth is the lesion producing the most severe and typical examples of Menière's disease; it generally involves the semicircular canals as well as the cochlea, and is therefore characterised by violent disturbance of equilibrium and vomiting; the hearing tests reveal absolute deafness or else dulness of hearing, most marked for the highest pitched tones. Many cases of Menière's disease are subsequently reported as severe deafness of sudden origin dating back from what had been looked upon as a severe "bilious attack." In most instances attacks of Menière's disease have been traceable to exposure to cold after being in a hot place, and occasionally to suppression or sudden stoppage of the menses; it is more liable to take place when there is increased arterial tension with weakened vessels or in the various blood diseases which favour the occurrence of hæmorrhage in various parts, such as leucæmia. In sudden functional deafness due to a nervous shock vertigo is not usually present—at all events, to any great degree—and the dulness of hearing is not markedly greater for the highest-pitched tones than for others.

Those forms having an *acute and rapid onset* are generally inflammatory, and occur frequently in the course of infectious diseases, particularly mumps, the rapidly developing and incurable deafness occasionally occurring in the course of this disease being an acute labyrinthitis. The following case (brought by Dr. Abercrombie) illustrates the condition:—

B. C., æt. 18, absolutely deaf in both ears, suffered

from mumps ten years ago. Towards the end of the first week of the disease vomiting set in; she became completely deaf in one ear; then, in the course of two days, equally deaf in the other one, the vomiting lasting for three days.

Apart from obvious feverish disturbances, such a rapid onset rarely occurs except as the result of syphilis, either hereditary or acquired. In the hereditary form it usually develops about puberty, and is, as a rule, preceded by interstitial keratitis and other physiological evidences, such as the notched and pegged "Hutchinson" teeth, are usually present. In a case (also brought by Dr. Abercrombie) deafness developed unusually early, namely, at seven years of age; the keratitis was extremely slight.

Of the forms of nerve deafness which are *gradual in development* the following are important types:—

The *anæmic* and the *congestive* are to be carefully distinguished, and the following points will enable us to do so in reasonably well-marked cases: In *congestion* there are usually collateral evidences of plethora; the patient's symptoms are worse on lying down or after the ingestion of food, or before the occurrence of the menses; they are made worse by the inhalation of nitrite of amyl, and are relieved by compression of the vertebral arteries. In *anæmia*, on the other hand, all these signs are reversed, and the constitutional signs of this condition are present, though sometimes to a very slight degree. In some cases the findings are those of *anæmia at one time and congestion at another*. I attribute this to irregular nerve control of the vascular supply, due as a rule to neurasthenic conditions. The treatment required follows as the obvious sequence of the diagnosis.

The most typical forms of *anæmia* occur in widows in the poorer class, who have to earn a meagre subsistence in return for laborious work, and who frequently present themselves for hospital treatment on account of their aural trouble.

Among other types are: the *senile* change which normally begins to show itself after the age of sixty, chiefly by loss of hearing for the highest pitched tones; *occupation* deafness the form occurring typically in artillerymen and boiler-makers; it also attacks the left ear in those who do much rifle shooting, and results from exposure to noises. *Toxic* nerve-deafness is particularly exemplified in the dulness of hearing produced by quinine or salicylic compounds, and it is probably congestive in nature. The *neo-marital* is an occasional form of nerve-deafness comparable to the amblyopia of young husbands described by Jonathan Hutchinson. *Neurasthenia* often gives rise to a form of nerve-deafness in which the deficiency is not especially marked for the highest-pitched tones; it is sometimes induced by over-work, excessive worry, the strain of active military service, and other analogous circumstances.

The following is a fairly typical case:—

A gentleman, *æt.* 36, engaged in the work of a bank, consulted me recently on account of deafness in both ears with slight tinnitus, resembling the sounds of sea waves, which had gradually developed during four years. Testing with the tuning-fork revealed the characteristic signs of nerve deafness; he had no vertigo; he heard worse when in the midst of a noise. His hearing for the whisper was 2½ ft. on the right and 2 ft. on the left, the watch being heard 1½ ins. and 3 ins. respectively. The hearing for the highest pitched tones was in the right ear only up to the mark 3·3 and in the left 2·0 of Galton's whistle. There was no family tendency to deafness, no evidence of gout and rheumatism; he had never been abroad nor suffered from malaria, and he had not been exposed to noises. Although his professional occupation was not a trying one he entered into its interests with an almost abnormal amount of conscientiousness, and in the evening habitually devoted himself to the teaching of religion. He rose very early, took a cold bath, and after a very light breakfast proceeded to his work in the city. His dinner was taken about midday, and was of a very moderate nature, so that he might be able to do his work in the afternoon; his only evening meal was the old-fashioned "tea," and if he took any food later in the evening it

was in the smallest possible quantity. He habitually abstained from stimulants. In the way of previous treatment he had three and a-half years previously been instructed by an eminent aurist to use a Politzer bag, and he had also employed a chloride of ammonium inhaler and other methods of inflation of the middle ear. The tuning-fork tests, the comparatively insignificant loss of hearing for high-pitched tones, and the general circumstances of the case led me to look upon it as one of neurasthenia. This was further evidenced by a nervousness of manner and extreme exaggeration of the knee-jerks. I induced him to undertake to give up his evening teaching, to take his work in general a little more easily, to allow his present midday dinner to count simply as a luncheon, and to have a good meal in the evening after the manner of other people in his social position. He was to take a small quantity of stout with one meal and a modicum of whiskey and water with the other. He returned to me a fortnight later, having carried out these simple instructions with his natural conscientiousness. There was marked improvement in his hearing power, and, in point of fact, the whisper could be heard at 6 ft. and 9 ft. with the two ears respectively. The result of this confirmed the conclusion as to the nature of his nerve deafness at which I had arrived.

Hysterical nerve-deafness is probably sudden in onset, but when affecting only one ear the patient may at first be unconscious of its occurrence, and on its discovery may be unable to state either the mode or date of onset. In the following case of hysterical hemianæsthesia with crossed amblyopia this point was exemplified:

Miss H—, *æt.* 41, schoolmistress, has frequently suffered from complete loss of voice and hoarseness since December, 1890; the voice had been restored from time to time by cauterisation of her throat at the hands of her medical attendant. She has suffered from purulent rhinitis affecting the various sinuses, and accompanied by frontal, post-ocular and occipital headache; both frontal sinuses were explored by me with comparatively negative results, there being no obvious retention of pus and no marked benefit from the operations. In 1895 I discovered that she had hemianæsthesia of the right side of the face and body, including the olfactory, auditory, and gustatory nerves, with diminished visual acuity on the left side. The tuning-fork tests showed the loss of hearing on the right side to be of the nature of nerve-deafness, and the loss of hearing was as pronounced for the lower tones as for the highest. Hearing-power is greatly diminished, but Galton's whistle can be heard up to the mark 3, practically the same as on the other side. The dimness of vision in the left eye is accompanied by complete inability to distinguish green and red from each other. The case is therefore one of hemianæsthesia with crossed amblyopia, and therefore presumably hysterical in nature. No remedies (hypnotism included) seem to have touched the condition, and she cannot be induced to undergo the rest treatment which is indicated in such cases. Possibly some accident or the occurrence of the menopause may break the spell.

I shall now narrate the case of a patient whom I brought before this association some years ago, as an extreme case of hysterical nerve-deafness with spontaneous recovery:—

Miss A—, *æt.* 18, came under my care on May 27th, 1895, complaining of deafness of both ears, stuffiness in the nose, and pain in the throat. The deafness to a slight extent was of three years' duration, and it had come on gradually and had suddenly got very much worse immediately after the extraction of eight teeth, three months before coming to me. For this operation she was anaesthetised with gas and ether. On examination the hearing was practically the same in both ears. She could only hear very loud conversation, and apparently only when her hearing-power was supplemented by lip-reading. The watch was heard at 6 ins., Galton's whistle was heard up to the mark 3·8, the bone-conduction of both mastoids was diminished, and Rinne's test gave a "positive" result in both ears. There was pain over the mastoids, no discharge was present, and there was no definite history of any previous discharge. At that time she described certain

indefinite attacks of giddiness, of which she has now lost all recollection. On testing her hearing for various tuning-forks by air-conduction, she was found to have completely lost the hearing for "C," and for "C₁," while for the other forks extending from "C" up to "C₂" the amount of hearing-power varied from three or four up to 15 per cent. A diagnosis was then made of nerve-deafness of indeterminate origin, but probably "auto-suggestive." Ammoniated tincture of valerian was ordered, blisters were applied to the mastoid process, and galvanism by means of the continuous current to the strength of ten milliamperes, with the negative rheophores, applied to the tragi, was employed for ten minutes at a time. The treatment was varied in the usual way, and the changes were freely run on strychnia, bromide of potassium, and ultimately the liquid extract of ergot. No improvement of any moment took place, and as a natural result the patient withdrew from further treatment. She later on came back to say that her hearing was perfectly good, it having returned in the January of 1897 after a "complication" of ailments which confined her to bed for a fortnight. While lying in bed her hearing rapidly improved, until in six months it became perfectly normal, and she can now hear a whisper by the right ear at the distance of about fourteen feet and by the left thirteen feet.

The spontaneous recovery seems to confirm the original diagnosis. In this case the tuning-fork test for middle tones "C₁" answered to the type of nerve-deafness, and they were sufficient to exclude middle-ear disease. The tests for air-conduction throughout the whole range of audition indicated that the maximum of loss was for deep tones. In typical cases of disease of the labyrinth the opposite would be the case, and we should expect to find the loss greatest in the uppermost part of the range, the lower part being relatively less defective. The combination, then, agrees with that described by Grandenigo as typical, on the other hand, of disease of the nervous centres, and, in fact, exactly of what he describes as occurring in hysterical nerve-deafness as set forth in his article in Schwartze's notebook. In his more recent publication on Auditory Disturbances occurring in Hysteria, he describes the loss of hearing as being fairly uniform throughout the whole range, but more marked in the lower range, on account of the physical nature of tuning-fork vibrations rather than from peculiarities in the auditory nervous apparatus.

The treatment of nerve-deafness depends primarily on the diagnosis of the variety, and the necessity of distinguishing between the anæmic and congestive forms must again be emphasised. That valuable drug, pilocarpine, has fallen into undeserved disuse through its unfortunate effects in cases for which it was not adapted. I have no hesitation in ranking it as a most beneficial remedy in congestive conditions of the labyrinth, but most deleterious in the anæmic ones. It may be administered hypodermically or by the mouth. The initial dose by the skin is about one-twelfth of a grain. At least double this dose is necessary for internal administration. The precautions to be observed during its administration are, of course, well known by all present. The other general remedies calculated to deplete are also advisable in cases of congestion. In anæmia and conditions of exhaustion our sheet-anchor is strychnine, and when such doses have been reached as to produce twitchings or other nervous disturbances the remedy may be combined with chloral. Iron and chloride of ammonium are also of value, and in neurasthenic conditions arsenic may be added. I have a strong conviction, on experimental evidence, that quinine produces congestion of the labyrinth, and is to be accepted as the physiological corrective of anæmia of that part. In a number of cases of what I took to be well-marked anæmic nerve-deafness, treated with quinine, under my own care and that of Dr. Wingrave, the benefit effected seemed to confirm this opinion most strongly.

I have, perhaps, not given to the electrical treatment of nerve-deafness the attention that it deserves. I have, however, seen improvement in several cases of "occupation" deafness which Dr. Lewis Jones has treated for me by means of the continuous current. In other

instances the results have not been so satisfactory, though, perhaps, with a more judicious selection of cases they might be better. In neurasthenic nerve-deafness general electrization may find a place, but supportive measures, such as the administration of cod-liver oil, malt extract, and glyco-phosphates have proved of great value. Among other useful remedies are arsenic, strychnine, and valerianate of zinc. The last remedy has been very strongly recommended to me by Dr. Bowles, who combines with it small doses of rhubarb or belladonna.

Syphilitic nerve-deafness, occurring in the course of the secondary stage of the disease, is fairly amenable to treatment, but the results in the tertiary form are eminently desponding. Competent observers have noted very rarely an improvement as the result of injections of pilocarpine. In my experience improvement has been only temporary. I have, however, seen benefit from the administration of iodide of potassium, in doses, however, of not less than one drachm every four hours, continued for several weeks. On the whole, we have to trust mainly to keeping up the patient's strength by means of cod-liver oil and other supportive agents.

The above remarks are far from exhausting the subject; but I venture to think that the most salient features have been included, and that I have dwelt mainly upon those points which are of the greatest practical importance. I trust others will amplify my description in regard to those forms of nerve-deafness with which they have had the most experience, and that they will also fill up the gaps which have been left by me.

CASES OF GASTROTOMY FOR RECENT GASTRIC ULCER. (a)

By C. W. MANSELL MOULLIN, F.R.C.S.,
Surgeon and Lecturer on Surgery to the London Hospital.

In two of these cases the immediate cause for operation was recurrent hæmatemesis.

The first case was that of a woman, æt. 26, who had suffered severely from attacks of indigestion for the last 18 months. Of late the pain had been intense, coming on immediately after meals or within half-an-hour, and radiating through from the epigastrium to the back. Until the last week actual vomiting had only been of occasional occurrence. Since then it had been almost constant. There had been a slight attack of hæmatemesis four months ago, and other attacks becoming more severe seven days ago, five days ago (twice), four days ago (twice), and on the morning of admission. On the last occasion the quantity is said to have amounted to more than a pint. Shortly after admission she vomited six ounces of almost pure blood. There was no history of melæna, but an enema given the day she came in brought away a considerable quantity of blackened blood. The pulse was 140 to the minute, very small in volume, and of low tension, and the patient was decidedly blanched. My colleague, Dr. F. J. Smith, under whose care the patient had been admitted, thinking that it was not advisable that she should be allowed the chance of losing any more blood, very kindly had the case transferred to my wards, and an operation was performed as soon as it could be arranged. The abdomen was opened in the middle line, and the serous coat of the stomach carefully examined. As there was no scarring or other sign of inflammation, the stomach itself was packed round with sponges, and opened by a vertical incision midway between the pylorus and the cardiac end. The angles of the incision were held open by pressure-forceps, and the mucous surface systematically everted and examined bit by bit, that covering the posterior wall being

(a) Paper read at meeting of Medical Society of London, March, 1902.

brought into view by introducing the hand through an opening in the great omentum, and lifting the wall of the stomach into the wound. A large vaginal speculum introduced through the opening in the anterior wall enabled the cardiac orifice and that part of the mucous surface which could not be brought up to be inspected without difficulty. A small ulcer was found on the anterior surface near the greater curvature. It corresponded fairly well with the ordinary description of a simple ulcer and had evidently been bleeding recently. There was no indication about its edges and no vessel was visible on its floor. An incision was carried round the ulcer and the whole of it excised down to the muscular coat, the gap that was left being closed by fine silk sutures, which served at the same time to stop the bleeding. The wound in the stomach was closed by a double set of sutures, and the opening in the abdominal wall secured with silkworm gut. Convalescence was uninterrupted except for a slight attack of parotitis on the second and fourth days. The patient vomited once after the anæsthetic. Small quantities of hot water were given by the mouth the same evening, and continued at frequent intervals for the relief of thirst, but for the first four days the feeding was carried out entirely by means of nutrient enemata. Solid food (fish) was given ten days after the operation, and a few days later the patient was placed on ordinary diet. She soon regained her strength, and since the operation has been perfectly free from the pain and indigestion which troubled her so much before.

The second case was that of a married woman, æt. 28, who was admitted into hospital on April 25th, 1900, for hæmatemesis. She was sent up in an ambulance with a history of having vomited blood at frequent intervals for four days. Shortly after admission she was sick, bringing up fifteen ounces of dark-coloured blood, and became very much collapsed. An operation similar to that already described was performed as soon as could be arranged. When the stomach was exposed an old cicatrix was seen near the cardiac end. This was excised, and then a recent but chronic ulcer with indurated edges was found by its side. In the floor of this ulcer was a bleeding branch of the gastro-epiploic artery. The ulcer was included in the incision, and the opening in the stomach wall, which was nearly three inches long and ran almost up to the cardiac orifice, secured by a double set of sutures. The patient was very much collapsed, but rallied under injections of strychnia and caffeine and rectal enemata. For the first three days vomiting was very troublesome. Then it ceased and the patient appeared to rally. She was able to take small quantities of jelly by the mouth. The bowels acted at first after enemata, and then spontaneously. The tongue became moist. The abdomen was soft, not distended, and moved well with respiration. But as in the former case, parotitis set in, first upon one side, then upon the other. Suppuration followed, and though relief was obtained when the abscess was opened, the patient died on the ninth day after operation. At the post-mortem examination, the opening in the stomach was merely held together by the sutures. The edges were sloughing, and there was an entire absence of repair. The kidneys were markedly granular and contracted. It is worthy of remark that parotitis occurred in both these cases, though there was suppuration in only one. As there had not been any case of post-operative parotitis in any wards for at least five years before, and there has been none since, it almost seems as if there must have been some connection between them; but they were not on the same floor or in the same ward, and the one died ten days before the other was operated upon, so that

in all probability it was merely a coincidence, but it was a curious one.

In the third case, that of a patient who was under the care of Dr. Capon, the immediate cause was uncontrollable pain and vomiting. The patient was a married lady, æt. 32. For some months she had suffered in a very severe degree from all the symptoms of gastric ulcer with the exception of hæmatemesis and mælena. These had never occurred. All the ordinary remedies, including prolonged rectal feeding, had been exhausted without obtaining the least permanent benefit. The patient had lost more than a third of her weight and was so weak that she could scarcely raise herself from her bed. The pain came on within a few minutes after swallowing food, and was especially severe at the ensiform cartilage. The skin over this region was exceedingly sensitive. Vomiting shortly after food was the rule. This relieved the worst of the pain, but it usually continued with more or less severity for some hours after anything had been taken. After consultation with Dr. MacLagan it was decided to explore the stomach, and on opening it a long narrow ulcer with slightly thickened edges was found lying at the bottom of one of the rugæ on the anterior surface close by the incision. It was about three-quarters of an inch in length and extended down to, but not into, the muscular coat. No other lesion of any kind could be found, though the whole of the interior was carefully explored in the way already described. The ulcer was excised, the mucous and submucous layers sutured together, and the stomach and abdomen closed in the usual way. In this case also vomiting continued for some considerable time. The pain disappeared completely and finally, but owing to the sickness it was some time before the patient could take sufficient food to enable her to regain her strength. Recovery finally was complete.

I may mention that in addition to these cases I published in the *Lancet*, of October, 1900, a series of three others, in which I had operated for hæmatemesis, all of which terminated successfully, the patients recovering completely without any drawback. Of five cases, therefore, in which I have operated directly for hæmatemesis, four have been cured, and I have little doubt myself that the fifth would also have survived, had not her condition been so desperate.

It is usually held that the advisability of operating in these cases can be settled at once by comparing the actual mortality of hæmatemesis in cases of gastric ulcer, with that which it is supposed might follow gastrotomy performed under these conditions. (The former is put down at from 3 per cent. to 5 per cent. The latter is estimated very variously according to the kind and severity of the cases selected. No such comparison, however, is possible under the present conditions. On the one hand the whole number of cases of hæmatemesis, trivial and severe alike (and the trivial ones are much the more numerous) is taken, and the mortality percentage calculated from that. On the other, only those cases which are absolutely desperate, in which the operation is performed as a last chance, after everything else has been tried and has failed, are reckoned at all. No one suggests, or has ever suggested, operating upon slight cases of hæmatemesis. They should be placed entirely on one side and not taken into calculation. The only comparison that can be made with any pretence at fairness is between those cases in which surgical measures are advised and declined and those in which they are advised and accepted. I have no doubt as to the result. In three of my five cases the patient was already so bloodless that transfusion had to be performed. In two others I had to decline to operate altogether—they were beyond even transfusion. The mortality of such cases, left to them,

selves without operation, is certainly not 3 per cent. or even 5 per cent.; it is much nearer 100 per cent. And they are the cases with which the only comparison can be made when the result of operation is the subject in dispute.

As no paper of this kind appears to be complete without statistics, and as the statistics of the mortality from gastric ulcer, and especially from hæmatemesis, vary a good deal according to the authority from which they are taken, I asked the medical registrar at the London Hospital, Dr. Wall, kindly to tabulate for me all the cases of hæmatemesis from gastric ulcer which had been admitted into the London Hospital in the five years 1895 to 1899 inclusive. All cases of hæmatemesis from cirrhosis, malignant disease, &c., were carefully excluded. The result is of decided interest. The total number was 246—202 women and forty-four men; and taking one year with another the numbers were very much the same in each. The total number of deaths from hæmatemesis was ten or 4 per cent. But the incidence of the deaths according to age was very singular. Under the age of thirty there were 153 women with only one death. Over thirty there were forty-nine women with three deaths, or 6 per cent. Taking the men, there were only five under thirty years of age with one death; and thirty-nine over thirty with five deaths. In other words, the mortality from hæmatemesis among the men over thirty years of age is 12½ per cent.; and taking all the men together regardless of age, nearly 14 per cent. So far, then, as the question of operation for hæmatemesis is concerned, there must, it appears to me, be one rule for women under thirty years of age and another for women over thirty, and especially for men. But in considering the advisability of operating in general in cases of gastric ulcer, there is another point that must not be forgotten. These figures are only concerned with the mortality caused by hæmatemesis. There are other causes of death in gastric ulcer besides this, and those causes must also be taken into consideration. When the percentage of deaths due to these is added to that due to hæmatemesis it must be acknowledged that the death-rate due to gastric ulcer, especially in the case of men or of women over thirty, is much higher than is usually believed.

I am fully aware that the treatment of gastric ulcer is and must remain in the hands of physicians. But it is becoming more and more evident every day that there are certain contingencies or accidents which may occur in the course of a case of gastric ulcer which, if the consequences are to be avoided, can only be met by the adoption of prompt and decisive surgical measures. This is admitted so far as perforation is concerned; but I maintain that the principle should be carried much further. It should include all those cases in which, in spite of rectal feeding and other remedies, the pain after food is taken continues with severity, as it did in the case I have described; in which vomiting after food obstinately persists, in which the patient is steadily losing ground, and in which medical treatment has been tried thoroughly for a sufficient length of time, say for some months, and has failed.

So far as hæmatemesis is concerned, it is clear that age and sex make a very material difference, and much greater risk may be run in the case of women under thirty years of age than in the case of those over thirty, and especially in the case of men. My own figures stand at only one death in 153 cases of hæmatemesis due to supposed gastric ulcer occurring in women under thirty. (I may say that I have reason to believe that that particular period of five years was an exceptionally heavy one.) Surgical treatment, however, can rarely be required in them. But if there is one single severe hæmorrhage in a

case in which the previous history suggests the presence of a chronic gastric ulcer (when the bleeding is probably due to an opening in an artery of some size, and is not merely capillary); if there are two separate attacks of severe hæmatemesis at a short interval, or if there are frequently such hæmorrhages, so that the patient is becoming seriously anæmic, I believe that the risk of operation is very decidedly less than the risk of leaving the patient alone, and that the best interests of the patient would be consulted by giving him or her the chance of operation before the condition becomes desperate.

NOTES ON A CASE OF TUBERCULOSIS OF THE GENITO- URINARY TRACT.

By J. P. C. KIRKPATRICK, M.D.,

Assistant Physician to Steeven's Hospital.

THE patient A. M., male, æt. 44, was admitted to Steeven's Hospital complaining of pain in the back and frequency of micturition. He stated that he had been in this condition for some six months past, but that the pain was gradually getting worse and gave him considerable trouble when he moved about.

On examination the pain was found to be localised to a small area in the left loin. The urine contained a small but constant quantity of albumin, but no pus or cellular elements, it was clear and acid in reaction. The left epididymis and vas as far as the external ring were hard and considerably enlarged, but not painful. Examination per rectum showed a small nodular enlargement in the left seminal vesicle. The lungs and other organs appeared healthy. Repeated examination of the urine for tubercle bacilli gave a negative result. Deep pressure over the left kidney caused the patient to micturate, but nothing more than an indefinite sense of resistance and fullness could be made out even when the patient was fully under the influence of an anæsthetic. Examination by X-rays for renal stone gave a negative result. As the disease of the genital organs caused the patient no trouble and all the symptoms pointed to the kidney, it was decided to expose that organ and remove it if necessary. Mr. Haughton opened the abdomen and explored both kidneys. The left was found enlarged and apparently cystic, while the right appeared normal. The patient, however, became so collapsed on the table that it was decided to postpone the removal of the organ to a subsequent date. The patient died three days after the operation.

At the post-mortem examination the right kidney was found to be slightly enlarged but apparently healthy, as was also the right ureter. The left kidney was converted into a large, semi-solid, caseous mass with little or no renal structure left, though the capsule was intact. The left ureter was filled with a similar material right down to its entrance into the bladder, and its lumen was completely obliterated. The bladder itself appeared quite healthy. The left epididymis and vas as far as the external abdominal ring were in a similar state of caseous degeneration, but that part of the vas which was inside the abdominal cavity was healthy except for a few scattered nodules of caseous material. There were similar nodules in the right vas and the seminal vesicles. None of the other organs in the body showed any signs of tuberculous disease. It is interesting to speculate, but I fear impossible to decide, what was the primary focus of disease. The patient could give no information as to the onset of the testicular enlargement; he stated that he did not even know of its existence till his attention was accidentally drawn to it while he was in the hospital.

Absence of any cellular elements in the urine was doubtless due to the fact that the ureter was completely obstructed and the renal tissue completely destroyed. Why, however, the renal symptoms, such as pain in the back and pain on passing water, and the frequency of micturition with the albuminuria, should have persisted is not very clear. The difficulties of an accurate diagnosis ante-mortem were very great, and the information gained at the post-mortem does not completely remove them; it was in the hopes that some of the members present would be able more accurately to connect the clinical symptoms with the pathological conditions that induced me to bring the case forward. I should have stated that the patient had no fever at any time during his stay in hospital before the operation.

A CASE OF SWALLOWING OF A METALLIC DENTURE SUCCESSFULLY TREATED BY THE INTERNAL ADMINISTRATION OF COTTON-WOOL.

By G. JAMESON JOHNSTON, M.A., M.B.,
F.R.C.S.I.,

Visiting Surgeon, Royal City of Dublin Hospital.

THERE are certain points of interest in the history, physical examination, and treatment of the following case, which have prompted me in bringing it before the Academy.

T. M., *æt* 20, was bathing at Blackrock on the evening of August 9th last, when nearly half a mile out he put up his arms with the intention of sinking to the bottom. On reaching the surface again, he was struck in the face by a wave, and immediately after found himself choking. His attempts to swim by a breast stroke being futile, he turned on his back and succeeded with some difficulty in reaching the shore in this posture. He called for assistance, and informed some bystanders that he had swallowed his artificial teeth; he was then conscious of the plate being stuck in the back of his throat, but had no difficulty of breathing. An individual who was assisting him struck him sharply on the back, when the plate changed its position and brought on a dyspnoic attack, rendering him "black in the face;" he was slapped on the back a few more times with the effect of relieving the breathing, though he suffered great pain. Dr. Flood saw him and advised his removal to hospital. The patient states that during the journey to town the jolting of the car caused the plate to go further down his throat, and that the seat of the pain became situated lower down.

I saw the patient soon after his admission to hospital, and found him in a very exhausted condition, pale and in a cold perspiration; he had no difficulty of breathing, but complained of severe pain, which he referred to the lower end of his sternum; neither digital exploration of the pharynx nor palpation of the neck revealed anything abnormal. I gave him a teaspoonful of milk to swallow, and the act was so painful he begged not to be given any more. I then passed a sponge probang without any appreciable resistance into his stomach. The passage of the instrument was evidently painful, and the probang returned smeared with bright blood. He expressed himself considerably relieved, in fact the relief was so marked and maintained as to suggest the possibility of the plate having been pushed from the lower end of the oesophagus into the stomach.

When the possibility of the plate not having been swallowed was spoken of the patient asserted positively that it had not been ejected, and was certainly swallowed. As there were now no urgent symptoms I reassured the patient and put him on 5 m. doses of liq. morph. mur. every three hours, with the double object of allaying the pain and minimising peristalsis. He suffered much pain on Friday night, all day on Saturday and throughout Saturday night; the pains, however, ceased early on Sunday morning. The pains were paroxysmal in character, and occasionally very violent. There was, on Saturday, a distinctly tender spot approximately over the pylorus. I watched carefully for signs of gastric peristalsis, but was unable to discover any, owing to the rigidity of the abdominal wall during the attacks. On Monday I was supplied with a wax model of the plate. The saw-like edge where the plate fitted against the posterior surfaces of the natural teeth, and the rather formidable (from an intragastric point of view) clasps for holding the plate in position, naturally suggested the question of gastrotomy. However, I decided to wait and administer cotton wool. Accordingly I ordered bread and butter sandwiches to be prepared with a thinly teased outlayer of cotton-wool in each; the patient relished the idea of the sandwiches and partook of them as freely as I permitted. I made no accurate estimate of the actual amount of cotton-wool used, but had in my mind a rough calculation of the amount which might possibly cause obstruction.

Dr. E. J. Watson kindly went to a great deal of trouble in examining the patient with the Röntgen rays, and notwithstanding that an extended examination was made on three successive days with the most recent apparatus, no indications of the plate were seen. The screen showed most distinctly metallic buckles and buttons through the whole thickness of the body. I can offer no explanation of the failure of the skiagraphic examination further than that the plate was in the small intestine and the peristalsis prevented the plate remaining sufficiently long in one position to be recognised.

Nothing of interest supervened until the following Friday, that is a week after his admission, when the patient was again seized with paroxysmal pains, this time referring them to the right iliac fossa. Without any leading question the patient stated that he was distinctly conscious of the plate being in that region and changing its position. Palpation over the ileo-cæcal valve caused the patient to wince and complain of pain. The pains were not nearly so severe as in previous attacks, and only lasted two hours.

His bowels not having been moved since his admission, I considered it safe to order some aperient, and he was given about 3ss. of liquorice powder. Next morning (Saturday) he had a motion, which was examined with negative results; three hours later his bowels were again moved quite painlessly, and the plate was seen to be enveloped in an admixture of

cotton-wool and faeces; the cotton-wool was easily removed from the left side of the plate where the clasps are not very prominent, but it required some little effort to remove it from the other side, where the large clasp was completely entangled in the wool. I regret that it is not possible to exhibit a photograph of the plate in the condition in which it was passed, as the enthusiasm of the nursing staff resulted in the plate being restored to me as clean and polished as when it left the hands of the dental practitioner who made it.

The patient left hospital next day and has been perfectly well ever since.

The plate weighed ninety-five grains and measured four centimetres long, by one and a-half wide; affixed were two teeth, the right lateral incisor and canine of the upper jaw, a long clasp for the right first bicuspid, there were indentations for the right central incisor, the two left incisors, and a short clasp for the left first bicuspid.

One can practically read the progress of the plate in the history. It would seem that the plate at first stuck in the back of the pharynx, and remained there until the patient reached the shore, as there was no obstruction to respiration. The slaps on the back which the patient received apparently caused the plate to change its position and press on the glottis, causing great difficulty of breathing with cyanosis and prominent eyeballs; renewed slapping relieved the dyspnoea, the plate slipping down into the oesophagus where it seems to have remained until he reached hospital. The location of the referred pain, namely, the lower end of the sternum and the practically instantaneous relief given by the passage of the probang, leads me to assume that the probang pushed the plate into the stomach, where it remained until Sunday morning. The passage through the small intestine lasted until the following Friday. The paroxysmal pain in the ileo-caecal region pointing to its passage through the ileo-caecal valve, the laxative given hastened the passing through the large intestine, which was terminated next morning.

I have already given the only explanation I can of the negative results of the Röntgen ray examination.

The treatment adopted in this case was not original, but is not, I believe, as widely known and appreciated as its obvious merits entitle it to be.

Clinical Records.

CASE OF ADVANCED HEART DISEASE TREATED BY THE INHALATION OF OXYGEN.

Under the care of GEO. Y. MYRTLE, M.R.C.S.,
L.R.C.P. Lond.,
Harrogate.

Mrs. K., æt. 71, has for many years suffered from dilatation of heart with mitral insufficiency, also slight rheumatic and gouty symptoms—of active habits and abstemious as regards both food and drink. She came to Harrogate for the last seven years in order to drink the saline chalybeate waters and have a course of the sulphur Nauheim baths, which benefited her health and enabled her to get through the winter months satisfactorily. For this end she returned last September. During the past winter she was confined to her bed for three weeks, and to the house for the same period on account of acute bronchitis of both lungs. This aggravated her heart trouble, and gave rise to difficulty of breathing on slightest exertion. She complained of a dull ache over the entire cardiac region sometimes approaching angina, and the loss of her soldier son in South Africa told very terribly upon her spirits, and gave rise to insomnia and anorexia.

Sept. 22nd.—My father (Dr. A. S. Myrtle) saw her, and told her she was altogether unfit to undergo the treatment she had on former visits, ordered her perfect rest and put her upon digitalis and nux vomica, with

three ounces of whiskey thrice a day. On the 26th my father again saw her; she was wanting to get up and go out. On the morning of the 27th he was sent for and found her lying on the left side, face, lips and finger-nails blue. She answered questions with difficulty, complained of acute pain over the heart, pulse feeble, rapid and irregular, respirations shallow, fifty-six to the minute. Gave her nitro-glycerine at once, and brandy, with sinapisms to chest and nape of neck. These relieved her, but not to any great extent. He then ordered a supply of oxygen (Brinn's) to be got, and as soon as it arrived I gave it for five minutes, with good result. Her colour improved, as also did the pulse and the respirations, which became deeper and less frequent. The pain also which she complained of almost left her. I gave her some more in about three-quarters of an hour's time as she said it had done her so much good and she enjoyed taking it. The oxygen was ordered to be given every two hours, or more frequently if required; she was able to take plenty of nourishment, and brandy and champagne. The same night Dr. Howell, her medical attendant at home, came down as he had been sent for, and on the following morning suggested 1-40 gr. strychnine hypodermically. This seemed to have no effect, and as the gas alone seemed to give relief we stuck to it and allowed her to inhale whenever she asked for it. The same night, the 28th, I was sent for as the nurse thought she was dying. I found her in every way worse, colour deeper blue, respiration 62, pulse very feeble and irregular; she was only semi-conscious, and certainly looked as if she was dying rapidly. I ordered oxygen and stimulants to be freely given and had hot bottles put to feet. The following morning she was better. Respirations continued 50 to 60 to the minute, pulse improved in character, temperature was normal, mind clear as ever, but occasionally there was great restlessness, kicking her legs about, and even getting out of bed and walking round it, tossing from side to side, but no pain, and she always said she felt quite comfortable; she slept for a few minutes at a time.

On October 2nd she looked and felt so well she talked of getting up and going out; she remained in much the same condition until the night of the 7th, when, on paying my evening visit, I found her sitting up in bed eating minced chicken and drinking champagne, talking strongly. Respiration 42, pulse 112, regular but rather feeble; an hour after I left her she was dead.

She commenced inhaling oxygen on September 27th, and from that date to the time of her death, October 7th, she had 420 ft. of the gas. I have no doubt a large quantity was wasted by the careless way in which it was allowed to pass through the tube, but still she must have had the benefit of one-third of the quantity, with the result that instead of dying in a few hours she lived for ten days in comparative comfort. Two or three points with reference to the use of inhalations of oxygen strike me.

First, it cannot be had readily, one has to send to Leeds or some other big centre when the local chemist has run out of his supply, so that a long time may have to pass before you can get the gas.

Secondly, it is an expensive remedy, costing 6d. per foot, so that the amount this patient had, came to ten guineas, a serious matter, often beyond the incomes of many who would benefit by it. Another point, by its use the life of a patient may be prolonged for hours, days, or even perhaps weeks, and this might prove of immense importance where the disposal of property by will or otherwise is necessary, or even time may be gained so that near and dear relatives or friends may have the opportunity afforded them of coming from a distance to say a last good-bye.

A Warning to Cats.

DR. PURCELL relates in a contemporary the untimely decease of a favourite cat of his which succumbed to the effects of the incautious ingestion of sundry bipalatinoids, sent as a sample, some of which fell on to the floor and were incontinently gobbled up by pussy. The bipalatinoids in question contained strychnine and arsenious acid *inter alia*.

Transactions of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.
CLINICAL MEETING HELD (IN THE ROYAL INFIRMARY)
ON MARCH 12TH, 1902.

Dr. T. R. FRASER, President, in the Chair.

MR. C. W. CATHCART showed (for Mr. Caird), (1) a girl, *æt.* 12, after removal of an intra-cranial tumour. She was operated on in November, 1900, because of constant twitching of the right side of the body following an injury to the left side of the skull, and several pieces of thickened bone were removed. The symptoms were temporarily alleviated, but recurred, and in February, 1901, a second operation was undertaken. On opening the dura, the brain bulged greatly, and a tumour the size of a cricket ball was shelled out from the Rolandic region. Since that time her general health had improved greatly, and headache had ceased, but there was still slight lameness and loss of power in the right arm. (2) A woman, after partial removal of an intra-cranial tumour. The patient had noticed the gradual development of a swelling over the left eye, and protrusion of the eye itself; these symptoms had been progressing slowly for about five years. Latterly pain in the head, vomiting, and mental confusion had been added. On operating, the swelling was found to be of a cystic nature, the cyst having pushed its way through the cranium; the cyst was removed, and below it a large tumour was found, which could only partially be removed.

Dr. F. D. BOYD showed a case of congenital paraplegia in a child, *æt.* 5. There was a history of prolonged labour followed by a hæmatoma. The patient has always suffered from fits, and was mentally deficient. His legs were spastic, the tendon reflexes being much exaggerated. The head measured 22 ins. in circumference—rather in excess of the normal at that age, pointing, Dr. Boyd thought, to the occurrence of congenital hydrocephalus as a cause of the delay in labour and the consequent injury to the brain.

Dr. ALLAN JAMIESON showed (1) a case illustrating the combined features of lupus vulgaris and lupus erythematosus on the same patch; (2) a case of lupus erythematosus which had very greatly improved after prolonged treatment by quinine, the patient having taken 15 grs. daily from June, 1900, to January, 1902; (3) a case of parakeratosis variegata; and (4) a case of pityriasis rosea.

Mr. C. W. CATHCART showed (1) a case of complete rupture of the tracheal plexus, in which all the nerves except that to the subclavius and the nerve of Bell were divided, and, contrasting with this, a case in which only the eighth cervical and first dorsal roots were torn. In the first case an unsuccessful attempt to reunite the upper branches of the plexus had been made; in the second case the injured roots were not accessible to the surgeon. (2) A case of excision of gangrenous bowel from strangulated hernia, with immediate suture of the intestine. (3) A case in which urgent cerebral symptoms were relieved by tapping the middle fossa in fracture of the base of the skull. The history was that the boy had fallen and struck his head, and that this was followed by convulsions and loss of consciousness. The patient was very restless when admitted to the hospital, and there was an offensive sanguino-purulent discharge from the ear. The mastoid cells were therefore opened, but nothing was found; the cranial cavity was therefore opened, when a quantity of blood-stained fluid escaped as soon as the dura was incised. (4) A case of Bazin's disease, in which scraping the ulcers had twice failed to bring about healing, but which was now improving under salicylic and creosote plaster.

Dr. BYRON BRAMWELL showed a man who had consulted him in June, 1901, and in whom the astereognostic sense in the left hand was for a time entirely lost. The ordinary forms of sensibility were entirely unimpaired; pain, touch, heat, cold, and muscular sensation being normal, but the patient was, nevertheless, quite unable to distinguish one object from another by the sense of feel-

ing alone. His complaint was that he could not pick things out of his pockets; he could not, for example, distinguish between a key and a coin. Otherwise he showed no signs of disease of the nervous system, except double plantar extensor response. He had not been treated in hospital, but had completely recovered, while, except for a temporary functional weakness of the legs, there had been no other nervous symptoms. Astereognosis had been much written about in America and on the Continent, but had attracted little notice in this country. One must suppose that a centre existed, possibly in the Rolandic area, to which all the other sensory centres sent fibres, and which co-ordinated the sensory impressions into a harmonious whole. Astereognosis might be due to disease; as this case showed (and it was an important one in that respect) it might also be functional. (2) A case of Bright's disease in which marked diuresis resulted from the internal administration of boracic acid.

Mr. ALEXIS THOMSON showed (1) a patient after suture of penetrating wound of the stomach. A gouge had been pushed through the abdominal wall below and to the left of the umbilicus, and had passed in an upward direction, perforating the anterior wall of the stomach close to the lesser curvature. (2) A patient, *æt.* 61, after operation for irreducible inguinal hernia containing a large diverticulum from the urinary bladder. The hernia had been present for twenty years; it presented no special features, and as it could not be controlled by a truss radical cure was advised. An ordinary hernial sac was found and in front of it a second sac containing the diverticulum of the bladder. It was at first thought to be an encysted peritonitic exudation and was incised. The wound was united, but a week later broke down and urine escaped from it. It gradually healed, however, and a good result ensued.

Dr. G. A. GIBSON showed an aberrant case of polyneuritis simulating Landry's paralysis. The history was of one month's duration, and there was no previous injury or infectious disease to which the onset could be ascribed. The legs and right arm were completely paralysed, and the left arm partially so. There was no loss of muscular tone, reaction of degeneration, or diminution of sensibility. The reflexes were abolished, and the nerves were tender when pressed upon. It was therefore an affection limited to the lower motor neuron, and he would have described it as actually a case of Landry's paralysis (seeing that most recent authorities regarded that disease as a variety of polyneuritis) were it not that there were no sensory disturbances, whereas in Landry's classical description, if one took the trouble to refer to the original paper, sensory disturbances were by no means absent.

Dr. GIBSON and Mr. COTTEBILL showed a patient, *æt.* 46, who had suffered from dyspepsia for three years, with, latterly, vomiting and loss of weight, and upon whom pyloroplasty had been done. There was absence of free hydrochloric acid, and the total acidity of the gastric juice was diminished, but there was no free lactic acid. The stomach reached to one inch below the umbilicus, and there was marked splashing, but no visible peristaltic wave or tumour could be made out. Absence of leucocytosis, too, was against cancer, so that the diagnosis of simple stricture was made, and it was confirmed at the operation.

Mr. COTTEBILL showed a case of dislocation of the radius on account of which he had removed the head of the bone and the remains of the orbicular ligament. The state of matters before operation was somewhat curious. Flexion was usually checked at a right angle and the arm could be almost completely extended. The patient could, however, luxate the head of the bone in such a way that he could completely extend the arm but not flex it; then, by again luxating the radius he could flex the arm but could not extend it again until he had once more altered the position of the head of the radius.

Mr. WALLACE (on behalf of Mr. Chiene) showed three head cases—one of a man who had developed epilepsy, taking as many as 180 fits in the day, about a year after a severe head injury; the second, a boy, *æt.* 7, who after an injury to the head became mischievous, semi-idiotic,

and the subject of fits; the third, a man in whom a recent injury to the head was followed by paresis of the arm and leg, and in whom epilepsy was developing. The first was cured by trephining, in the second no benefit followed operation, in the third no operation had yet been carried out.

Dr. NORMAN WALKER showed (1) a case of rodent ulcer treated by arsenious acid; (2) a case of mild ichthyosis, illustrating the fact that the condition was not always (as was generally supposed) congenital; and (3) a case of urticaria pigmentosa.

Dr. GIBSON showed a brain from which a cerebellar tumour had been removed.

Dr. W. ALLAN JAMIESON demonstrated the new Marshall and Wood's lamp used for the treatment of lupus by light.

HARVEIAN SOCIETY OF LONDON. CLINICAL MEETING HELD MARCH 20TH, 1902.

Mr. W. WATSON CHEYNE, President, in the Chair.

Mr. ROUGHTON showed a child seven months old after operation for intussusception. Four weeks ago the child was brought with the complaint that it had been sick more or less continuously since last Christmas, and that on the previous evening it was taken considerably worse, and began to pass blood and slime. The condition was at once suspected, and on palpation a small swelling was found above and to the right of the umbilicus. Injection was not resorted to, but the abdomen was at once opened and an intussusception of the ileo-cæcal variety was found, which had only travelled as far as the hepatic flexure of the colon. It was reduced with ease. He afterwards noticed that the vermiform appendix presented a bruised appearance in its distal one and a half inches, and he accordingly removed it.

The PRESIDENT said he had taken a fancy to combining the two methods, that of injection and of abdominal section. He opened the abdomen and located the intussusception, then injected fluid slowly per rectum. Then if the fluid did not seem to be doing good the bowel could be brought out and the intussusception removed.

Mr. ROUGHTON showed another case in a child, 13 months old, who was operated upon at the age of 4 months, when the symptoms had lasted twenty-four hours. He reduced the trouble easily except the last two inches, but that occupied a quarter of an hour and was very troublesome.

Dr. CAULEY supported the combined method of reducing an intussusception. The great drawback to relying upon the older method of reduction by water alone was that it was impossible to tell whether the intussusception had been completely removed.

Mr. ROUGHTON, in reply, said he did not propose to try the combined methods mentioned by the President. He had only operated upon three cases of intussusception, and they had all recovered. Injection had not been used. He thought the fluid must distend the bowel, and that would probably be a greater source of shock than manipulation outside. He did not see why such cases should not recover if operation were done sufficiently early, say, within twenty-four hours.

The PRESIDENT showed a man who had fractured both patellæ, one of which had been treated by wiring and the other not, and remarked the secret was not to put the leg in a splint, but to make the patient walk as soon as possible.

The PRESIDENT also showed a boy who a year ago fell from a parapet a distance of twenty feet and fractured the left femur above the condyles. When seen the lower end of the upper fragment was in the lower part of the popliteal space, behind the tibia. Reduction was tried, but every time the force was relaxed it shot back again. The application of heavy weights was also tried, but without permanent success. Eventually he made a long incision, turned back everything, and exposed the bones. It was found that not only was the femur fractured across, but the condyles were down in the joint and the ends of the bones went in between the

condyles separating the two halves. He therefore nailed on the outer side a plate of aluminum, fastening it with silver tacks. The leg was put into a splint and kept there for a long time, because the bone was so thin. For a time the lad had a stiff knee, but he could now bend it to a right angle. The plate was still in situ. He found the use of the plate an excellent measure in such cases, and he had treated several by it. It would be an advantage to have the plate and the nails of the same metal, to obviate any possible electric action.

Mr. JACKSON CLARKE showed a boy the subject of severe spastic paralysis one year after operation. He had shown the boy before operation, and shortly afterwards. The right leg had been particularly stiff, but was now more useful, though he still walked plantigrade. There had been a lot of clonic movement, and he did an elongation of the tendo-Achillis on the right leg which caused the stitches to give way over that. Instruments had been left off during the day, but were resumed at night. He did not believe tendon transplantation had been very useful for the condition. He thought the prognosis after operation in such cases was more hopeful than he had been taught, and than he at one time believed.

Dr. CAUTLEY believed that anything which would assist such children to walk would also assist their mental development. He thought in all cases of spastic paralysis that any operation which would enable the patients to stand, and later to walk, should be done, even though the child might not be mentally competent. Once they associated with other children and could play with them, the mental and physical development was improved.

Dr. LEONARD GUTHRIE showed a case of Charcot's disease in both hip-joints in a woman, æt. 44. Twelve years ago she had slight pains in the limbs which did not last long. Three years ago they were much worse and of a lancinating character, and there was numbness about the soles of the feet. At about that time a sudden swelling arose in the neighbourhood of the right hip, but it was painless. But she thought the bone was out because she could hear the bones rattle. Six months ago the other hip was similarly affected. The patient had the Argyll-Robertson pupil, and the left pupil was larger than the right. Romberg's sign was marked, and she had absence of knee-jerks on both sides.

Dr. GUTHRIE, in reply, said he thought that the absence of pain was due to anaesthesia of the joint nerve, just as there was anaesthesia elsewhere, and that the affection of joint was due to degeneration in consequence of the nerve trouble. There was a history of syphilis in the case twenty years ago, shortly after marriage.

Dr. GUTHRIE next showed a case of arrested growth of the fore-arm following fracture, with ischæmic paralysis, in a man, æt. 58. The condition of Voelckman's ischæmia was of fifty years' duration. At nine years of age he fractured both bones of his left fore-arm, and tight bandaging and subsequent ulceration resulted in firm flexion of the wrist when the splints were taken off. The fingers were bent into the palm of the hand and there was no use in the fingers. Operations had since been performed with the view of increasing the length of the contracted tendons. There was a difference of two and a-half inches in the measurement of the two sides. The bones of the left fore-arm were small, infantile in appearance, and somewhat glossy. Reaction to Paradism could be obtained in both flexors and extensors. The condition had been known to follow the application of Esmarch's bandage. Voelckman thought the condition was due to rigor mortis produced by stoppage of circulation, others that it was a purely nervous phenomenon. The previously described cases had been in children and had not been watched long enough.

Mr. Raymond Johnson, Mr. Jackson Clarke, and Dr. James Taylor also took part in the discussion.

MAJOR BRUCE MORLAND SKINNER, R.A.M.C., has been appointed Secretary to the Advisory Board for Army Medical Services, an appointment which carries with it additional pay of £100 a year.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD AT PADDINGTON GREEN CHILDREN'S HOSPITAL, MARCH 21st, 1902.

Dr. H. ASHBY (Manchester) in the Chair.

Dr. A. E. SANSOM showed a case of Hodgkin's disease in a girl, *et. 8*. The glands on the left side of the neck were greatly enlarged, and the spleen occupied the left half of the abdomen. The child was anæmic, and the leucocytes were deficient. The disease started four years previously subsequent to measles.—Dr. R. HUTCHISON remarked upon the tuberculous nature of several examples of the disease he had examined, and upon the impossibility of determining post-mortem from the naked eye whether they were tuberculous or not.—Dr. MORISON and Dr. KELSON commented upon the case, and Dr. SANSOM replied.

Dr. HARCOURT GERVIS showed a case of double aortic disease in a boy, *et. 13*, in whom a presystolic murmur was present at the apex.—Dr. SANSOM thought the presystolic murmur did not indicate mitral stenosis, but was an example of Flint's murmur.—Dr. MORISON was of opinion that pericardial adhesions were partly responsible for the enlargement of the heart, and spoke of the propriety of surgical interference in selected cases.—Dr. THEODORE FISHER (Bristol) considered that pericardial adhesions to the chest wall did not produce cardiac enlargement, and consequently thought surgical interference would be inadvisable even if the case could be diagnosed.—Dr. HARCOURT GERVIS replied.

Mr. ARNOLD LAWSON showed a case of congenital proptosis in a child, *et. 3*, and thought it due to imperfect development of the base of the skull and the orbital plates.—Mr. W. H. JESSOP discussed the case and agreed with the diagnosis.—Dr. HUTCHISON said he had a similar case under his care.—Mr. CAUTLEY referred to the high palatine arch in the case.—Dr. SUTHERLAND thought whatever mental defects were present were only apparent and were due to defective hearing consequent upon the presence of post-nasal adenoids.

Dr. CAMPBELL POPE showed a case of infantile scurvy in a female infant, *et. 8½ months*, which had been fed on patent foods and had developed hæmaturia, periosteal hæmorrhages, and gingivitis. The symptoms had started three months before. The existence of hæmaturia had suggested the presence of a renal calculus, and the child had been examined by the X-rays.]

Dr. GEORGE CARPENTER read a paper on a case of scurvy in a rickety boy, *et. 5½*. The gums were affected, and the child's dietary, owing to his curious tastes, was very defective. Dr. Carpenter discussed the etiology of scurvy, and called attention to the difficulty which is experienced in arriving at a definite conclusion as to the exact causation of these cases.—Dr. SUTHERLAND said that in his experience the prognosis was often grave.—Dr. CAUTLEY discussed the question from the point of view of infant feeding, and thoroughly endorsed the remarks made by Dr. Sutherland on the injurious effects of patent foods.—Dr. C. W. CHAPMAN called attention to the value of fresh milk.—Dr. H. ASHBY (Manchester) spoke as to the obscurity surrounding the causes of infantile scurvy.—Dr. THEODORE FISHER thought that in fatal cases death might be due to secondary infection; and Dr. CARPENTER replied.

Mr. W. P. MONTGOMERY (Manchester) showed a specimen of an inverted Meckel's diverticulum, which had formed the apex of an ileo-colic intussusception. The condition was, he stated, a rare one, there not being more than six cases on record.

Dr. THEODORE FISHER (Bristol) showed a specimen of congenital disease of the heart from a child, aged four months, in which a wide communication was present between the aorta and pulmonary artery, and attached to both pulmonary and aortic valves were large vegetations. Dr. Fisher also showed a stomach from a case of diphtheria in a child, *et. 3*, which was dotted over with numerous petechiæ; there were no petechiæ elsewhere, the large intestine excepted. There had been hæmatemesis two days before death.

Dr. H. ASHBY (Manchester) read a paper upon a case of combined empyema and purulent peritonitis. A girl, *et. 8½*, was seized with vomiting and diarrhœa, followed by pleuro-pneumonia and peritonitis. An empyema and suppurative peritonitis followed. Pneumococci and the micrococcus tetragenus were found in the pus of the empyema, and the micrococcus tetragenus in the peritoneal pus. The girl made a good recovery.—Dr. A. E. SANSOM complimented Dr. Ashby on his paper.—Dr. THEODORE FISHER said that he had made post-mortem examinations of cases of combined pleural and peritoneal infections due to the pneumococcus and other organisms.—Dr. DAVID NABARRO called attention to the pathological records of the Evelina Hospital for the past year of cases in which peritonitis was associated with empyema.—After remarks by others, Dr. ASHBY replied.

Special Article.

ARMY MEDICAL SERVICE.

A Royal Warrant and Instructions relating to the Army Medical Service were promulgated last week, of which the following is a summary:—

The Director-General of the Army Medical Service and the other officers of the Army Medical Staff shall hold the substantive rank of surgeon-general. The undermentioned officers shall rank as follows in relation to combatant officers for the purposes specified in the King's Regulations:—As Lieutenant-General.—Surgeon-general holding the appointment of Director-General, Army Medical Service. As Major-General.—Chaplain-general and surgeon-general.

An officer shall be eligible for promotion to the rank of captain on the completion of 3½ years' service, and to the rank of major on the completion of 12 years' service, provided that in each case he has previously qualified in such manner as may be prescribed by the Secretary of State. Promotion to the rank of lieutenant-colonel shall be made by selection from officers who have completed at least 20 years' service, and have qualified in such manner as may be prescribed by the Secretary of State. If an officer has passed with distinction the examination qualifying for promotion to the rank of major, the period of service required to render him eligible for the rank of major or lieutenant-colonel may be reduced. A lieutenant in the Royal Army Medical Corps promoted to the rank of captain before the date of this Warrant on account of distinguished service in the field shall be eligible for further promotion to the rank of major, and subsequently to that of lieutenant-colonel, when the officer next below him in the rank of captain or major completes 12 or 20 years' service respectively. A captain so promoted to the rank of major shall, on the same conditions, be eligible for promotion to the rank of lieutenant-colonel. An officer who may in the opinion of the Secretary of State have been prevented, under very special circumstances, from qualifying for promotion, or who, having failed to qualify, may have been debarred from further opportunity of qualifying, may be provisionally promoted. If, however, he fails to qualify on the first available opportunity his promotion shall be cancelled, and he shall be retired from the service. Promotion to the rank of colonel shall be made by selection from lieutenant-colonels who have been specially selected for increased pay, and from lieutenant-colonels or surgeon lieutenant-colonels of the Household Troops specially recommended to the Secretary of State for distinguished service in the field. Promotion to the rank of surgeon-general shall be made by selection from colonels. A colonel may also be promoted to the rank of surgeon-general for distinguished service in the field. The appointment of Director-General of the Army Medical Service shall be for three years, unless the term is specially extended by the Secretary of State for a further period not exceeding two years.

The following shall be the rates of pay of the officers of the Army Medical Staff and Royal Army Medical Corps, &c.:—

medical officer of Our Royal Malta Artillery, placed on the half-pay list on account of medical unfitness shall, if not previously retired, be retired from Our Army at the expiration of five years from the date on which he was placed on the half-pay list, or, if reported by the regulated medical authority to be permanently unfit for duty, on the officer's application, at such earlier date as may be decided by Our Secretary of State.

An officer, whether on full or half-pay, placed in detention as a person of unsound mind, shall be retired from Our Army, with the retired pay to which he would be entitled if reported by the regulated medical authority to be permanently unfit for duty. If his disability was not caused by Military service, and he is not entitled to permanent retired pay by length of service, he shall receive temporary retired pay equivalent to the half-pay and temporary retired pay, if any, which he would have received if his disability had been other than insanity.

Secretary of State's Instructions.

The term "rank," when used in the foregoing Royal Warrant, means "substantive rank" unless otherwise stated. Officers who have served with the Royal Army Medical Corps (Militia) when embodied, or who, as officers of the Royal Army Medical Corps (Militia) or Royal Army Medical Corps (Volunteers), medical officers of Yeomanry or Volunteers, or as civil surgeons, served with an Army in the field, after October 1, 1890, may be allowed to reckon such service towards retired pay and gratuity.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 29th, 1902.

At the meeting of the Medical Society, Hr. MAX gave an address

THE BACILLUS OF SYPHILIS.

His communication was a contribution to the subject. His investigations were based on the remarkable fact that old syphilitics have marital intercourse without infecting their wives until they become pregnant, when they alone, or along with the fetus, become infected. He suspected from this that the infection germs were longest kept alive in the semen, and that the placenta must be a particularly favourable nutrient soil. He made use of the semen of twenty-two men whose infection was from five weeks to three and a-half years old, and which, judging from symptoms, was still fresh. When this was inoculated upon placentæ, after thirty hours there developed grey, translucent, flat lying, only slightly raised, colonies of tenacious consistence. These consisted of bacilli bearing a resemblance to those of diphtheria, i.e., both ends were knobby. After a short time these cultures decomposed; if they were implanted upon agar or blood serum they revived, although if inoculated in the first instance on to these soils the semen did not yield these bacilli.

In five cases of syphilis four to ten years old the results were negative, with the exception of one case of five years' standing. Inoculation of four non-syphilitic individuals also gave a negative result.

On the syphilitic placenta, the bacilli only grew sparsely and poorly. They did not develop from dead semen, nor did they grow from two cases of azo-spermia; in one of them, however, a recently infected case, they were found in the blood. The examination of other syphilitic products, primary lesions, papules, condylomata, &c., was not yet complete, but was in progress.

Pure cultivation had no effect on mice, rabbits, or guinea pigs. Latterly, it had been thought that pigs were susceptible. The speaker injected a pure bouillon cultivation of his bacilli into a pig four weeks old and as a matter of fact the animal got a rash localised on the posterior half of the body. One animal experiment was not sufficient to justify any conclusion, statistical determination of their presence was necessary, and for this further and more extensive investigations were necessary.

Hr. Jürgens thought that the organisms shown were the same as those already described by v. Nisser as the germs of syphilis; they were not bacilli, however, but spores. Whether they had anything to do with syphilis was very questionable.

Hr. Aronsohn asked how it was possible that a bacillus which grew readily and quickly upon all soils should always require for its development placental structure as a medium. There was no analogy for it. It was also striking how the pathogenic agent of such a chronic disease as syphilis, in comparison, for example, with the tubercle bacillus, should grow so quickly on an artificial soil.

Hr. Blaschko thought that if they were really the pathogenic organisms of syphilis they would have been discovered long ago, considering their size and ready colourability.

THE RELATION BETWEEN DIABETES INSIPIDUS AND MELLITUS.

Dr. Kuhn, Berlin, related a case illustrative of this connection in the *Munch. Med. Wochensch.*, 3/1902. The observation is a rare one, inasmuch as the disease was recognised as diabetes insipidus shortly after its commencement, and about a week before the death of the patient it underwent a change and became diabetes mellitus. The case may be taken as proof of the close connection between the two diseases. As regarded pathogenesis, the autopsy favoured the belief that metastatic diseased glands in the region of the solar plexus, caused degeneration by pressure, this bringing about tissue changes.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 29th, 1902.

PROPHYLAXIS OF TUBERCLE.

WERCHSELBAUM in replying to Winternitz said the regulations at present existing were too recent to attempt any statistics that would prove a reduction of tuberculosis. Cornet has repeatedly told us that since the new orders at the Catholic institutions the death-rate has fallen from 155 to 65 in every 10,000. Prussia, New York, and England had receded a third.

He recommends light, airy dwellings, &c., to combat what we did know would be of advantage to the public, but the susceptibility to the disease could not avert, although the bacilli was certainly destroyed by light and air, which is the best protective for such subjects, and this could only be done by healthy dwellings which is the most momentous problem we have to solve. Infection and disposition are the two factors. We know the morbid agent and its products, we have a knowledge of the transmission and how to destroy it, but we still have a vague idea of the susceptibility.

URETER DUPLEX BILATERALIS.

Knopfmacher showed a pathological preparation of ureter duplex bilateralis taken from a girl, *æt.* 4, discovered when operating for a retro-peritoneal tumour in the left side. On examining the patient before the operation a large quantity of pus containing streptococci could be pressed from the vagina. The post-mortem revealed a double set of ureters passing from the renal pelvis to the bladder. One of the left ureters on closer examination was found discharging into the vagina, while the other three passed regularly into the bladder. It was from this ureter the pus seems to have been discharged, the poison passing from the vagina to the renal pelvis. It appears to have been a double malformation of the Wolfian bodies and Müller's canals.

RENAL TRANSPLANTATION.

Ullmann recorded the results of an experiment which he had conducted in totally transplanting a kidney to the subcutaneous tissue of the neck in a dog. He arranged the operation in such a way as to connect the arteria renalis with the carotid and the vena renalis with the vena jugularis, while the ureters were allowed to discharge on the surface of the body. The transplanted kidneys not only took growth and incorporated themselves in this new position, but commenced to secrete urine profusely.

Eiselsberg reminded the meeting of Brown-Séquard's facts that in the case of animals deprived of their kidneys uræmia could be averted by injecting a renal extract. Biedl said he had similarly experimented and injected the renal extract, which certainly removed the pulmonary phenomena, or Cheyne-Stokes' symptom, but not the poisonous phenomena.

Kreidl further stated that Alfred Exner performed this operation of total transplantation of the kidney in dogs four years ago, and that two of the animals operated on died of sepsis; in one, however, the kidneys became incorporated, and commenced to secrete urine on the third day.

HEPATIC CHANGES.

Topfer related to the meeting the results of his experiments in the changes that took place in the liver after the removal of the bowel. He first connected the aorta with the vena portæ after the removal of the bowel, and found that the liver was not able to change albumin or break it down till it had first passed through the bowel. This, he considered, proved the fact that albuminoid material must receive some stimulating action in the bowel to carry through the changes in the liver.

THE INTERNAL ORGANS AND SKIN ANOMALIES.

At the Doktoren Collegium, Ullmann read an exhaustive paper on the relation of internal disease to skin affections. A large number of morphological efflorescences had different etiologies, in spite of the fact that our system of treating skin diseases was in a great measure local and etiologically based on cutaneous origin. Correctly described, the skin affection is but a symptom of the internal disease, or a coincident causal effect. Colouring in the skin of icterus, bronzing, chloasma, or the ectasia of vessels in rosacea were only the effect of changes in the internal organs.

Such local conditions may occur in the nerve system in the form of herpes zoster, trophoneurosis, decubitus

acutus, mal perforant du pied, circumscribed oedema, and analgesic zones which often occur in hereditary conditions, although many of them are due to toxines or auto-intoxication.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

AMPUTATION FOR SENILE GANGRENE.—MODIFICATION OF STEVEN SMITH'S OPERATION.—Mr. CARLESS operated on a man, *æt.* 85, who was the subject of senile gangrene. The trouble had commenced in the right foot, and the disease had lasted a couple of months. The toes were all gangrenous and the necrotic process had extended upwards on the inner and outer aspects of the foot to above the base of the metatarsal bones, but a tongue-shaped area of living tissue extended into the necrotic area over the line of the arteria dorsalis pedis. Some amount of ulceration was present above the line of demarcation; the parts were horribly offensive. The patient was the subject of extensive calcification of the peripheral arteries, the radial and temporal being alike rigid and calcareous; the femoral artery beneath Poupart's ligament was somewhat rigid, but fairly good pulsation was present in it. Before operating Mr. Carless pointed out that necessarily serious risk was connected with an amputation, since it would be useless to operate below the knee as the tibial vessels would be certainly calcified. The patient, however, was not improving in spite of every precaution; he was becoming delirious at night and opium was constantly required to relieve his pain. The risks of the case had been put before the family, and they, as well as the patient himself, agreed to the performance of the operation. Preventive hæmostasis was effected by elevating the leg for about three minutes, and then binding around the thigh an elastic bandage over a piece of cyanide gauze. The rubber rod was not used, for fear of injuring the main trunks. An elastic band, Mr. Carless said, diffused the pressure more evenly, and would probably be equally efficacious. The operation performed was a modification of Steven Smith's disarticulation through the knee-joint, which has been proposed by Mr. Steven Smith himself, in order to meet the requirements of these cases; it was practically an inversion of the original method. A vertical incision was made down the middle line of the anterior surface of the limb externally from two inches above the patella down to the tubercle of the tibia, from this point incisions were swept round the limb on either side almost transversely, uniting in the middle line about two inches below the crease of the knee. Skin flaps were dissected up on either side as high as the level of the joint, whilst in front the flaps were dissected back so as to expose the patella. Incisions down to the bone were then made above and on either side of the patella, which was drawn down; disarticulation was now rapidly effected, the soft tissues behind the bones being cut through transversely; it was then found that the flaps provided were insufficient to cover the condyles, and therefore a saw was applied transversely so as to remove about the lowest inch of the femur, whilst the corners of the condyles were chipped off with cutting pliers; the main vessels were then secured, and the tourniquet released. Several other vessels required ligature; finally the

wound was stitched up, a drainage tube being inserted in the postero-inferior angle. The whole operation including the closing and dressing of the wound took only twenty minutes, of which the dressing was responsible for four minutes. Mr. Carless remarked that this modification had one great advantage over the original operation of Steven Smith; in the latter the blood supply of the flaps was always defective; whilst in the modification the main vessels could be divided at a lower level, and consequently the origin of the articular arteries was not interfered with, the surgeon only dividing their terminal anastomoses in the middle line in front. It was obvious, however, he thought, from this case that the instructions given by Steven Smith as regards the length of the flaps, which had been carefully followed in this instance, did not always supply a sufficiency of covering; if he (Mr. Carless) performed this operation again he would he said modify it by dividing the femur just above the condyles and then removing the lower end of the bone from the subjacent tissues so as to secure a division of the popliteal vessels low down. The method, he remarked, was a rapid and simple one and might be anticipated to give a good result, even in a debilitated individual like the present patient.

It is satisfactory to state that the patient stood the operation admirably, sleeping well on the first night, and that the wound looked very healthy on the second day when the drainage tube was removed.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d., Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 2, 1902.

THE NEW ROYAL WARRANT FOR THE ARMY MEDICAL SERVICE.

THE appearance of a new Warrant for the purpose of amending the regulations of the Army Medical Service is an event of great import to the future of that important service. Its chief provisions will be found on another page of our present issue. They deal with the appointment, promotion, pay, and non-effective pay and rank of Army Medical officers. So far as the document goes it may be regarded upon

the whole as satisfactory, although it leaves untouched various "burning" questions, such as the provision of an Army Medical School and Hospital in London. The increase of pay of medical officers is satisfactory, and arrangements have been made for additional charge and extra-duty pay. Retirement pay appears to take the form either of a pension or a gratuity, presumably at the option of the retiring officer. In this and other points the Warrant has followed pretty closely the recommendations of Mr. Brodrick's Committee. It is satisfactory to note the spirit of the present attempt towards the reorganisation of the Army Medical Service, the defects of which, as an official system, have been so emphatically demonstrated by the complete breakdown of that branch of administration in the South African campaign. At the same time the splendid material of which the Army Medical Service is composed has been shown by their achievements in the face of almost hopeless difficulties. The problem of how to restore efficiency and popularity to the Army Medical Service will demand most careful and statesmanlike handling for its solution. There are many points involved beyond mere rank and pay, important as those questions undoubtedly are. The omissions from the Warrant will come as a distinct disappointment to those who had hoped that the hand of the reformer would be no longer delayed. Nothing is definitely laid down as to examinations for appointment and for promotions. As regards appointment it is simply stated that commissions shall be given to persons duly qualified under regulations to be approved by the Secretary of State. From that clause it does not appear that even an entrance examination will necessarily be imposed. In like fashion the steps of promotion are left to the discretion of the Secretary of State, except the case of promotion to the rank of major, in which case the warrant clearly defines the time of service that can be saved in attaining the next step by passing the qualifying examination with distinction. Reading between the lines of the Warrant it may be, perhaps, permissible to assume that in all probability the recommendation of Mr. Brodrick's Committee with regard to the successive examinations for promotion will be adopted in principle, although the very vagueness of the present document seems to show that the matter is still under official consideration. The application of the high standard examination list is to some extent fallacious under any circumstances, and its extension to men of middle age can hardly be regarded as anything but a highly interesting theoretical and tentative experiment. It would be somewhat amusing to take, say, a distinguished professor of medicine and subject him suddenly to a high standard examination upon some subject in which he was neither examiner nor teacher. Of course, were he given a few months notice he might readily come to the ordeal prepared to "floor" his examiners. That is just what the medical officer of the future will be asked to do under an examination scheme of promotion. The value of

the test has been fiercely assailed, and doubtless the adverse criticism will cause more or less modification of the original recommendations. Among other matters remaining to be dealt with at some future time is the thorny question of service in India, which is beset with many grievances. Another vital point is the organisation of a sanitary department, not less as a peace than a war service. We ventured on a former occasion to suggest that the War Office would do well to offer a number of posts in any new sanitary department to experienced civilian medical officers of health. That suggestion has been adopted so far as the supervision of the refugee camps in South Africa has been concerned. One other urgent reform may be mentioned, namely, the raising of the numerical strength of the establishment to an adequate footing. The paucity of officers has given rise to many of the grievances and the defects under which the Army Medical Service at present labours. One of the greatest drawbacks to the Army Medical officer has always been the difficulty of obtaining reasonable leave. It is to be hoped that the wave of reform which is supposed to be about to sweep over our national army system will establish the Army Medical Department on a sound and efficient basis. So far as the new Warrant goes its regulations may be hailed with satisfaction as an honest attempt towards the solution of a most difficult and complicated problem. May it prove the harbinger of lasting and solid reform!

SURGICAL INTERVENTION IN DEMENTIA.

It is many years since R. W. Smith asked the pertinent question: "What is the relationship between fragilitas ossium and insanity?" No answer has been attempted for half a century, and it was only when we found how intimate the relationship between the thyroid gland, myxœdema and dementia that the deep significance of the inquiry was recognised. The mental affection must be looked on as an essential part of the general disease in many cases. The commonest of all chronic forms of insanity, melancholia, tells that it was so considered in the long past, when Hippocrates gave heliobore to purge out the offending humour, as later Aretæus, Celsus and Galen gave aloes. That a slight modification in the functional activity of a gland, or the alteration of a secretion will produce mental troubles, transient and sometimes permanent, is well known. That many of these cases recover their mental activity under treatment is common knowledge. Clouston's classical lectures tell of many such. All practitioners have seen cases of dementia in chlorosis, and the exanthemata; with these we do not purpose dealing. But we wish to draw attention to the unexpected recovery from chronic insanity which sometimes follows from a surgical operation, the object of which had no connection with the mental disease. Such cases are scattered throughout medical literature, and we cannot do more than briefly refer to some of hypochondria, a form of

insanity which is too often looked on as harmless, but which in our opinion is more likely to give rise to homicidal and suicidal tendencies than any other form of chronic mental disease. One of these cases: An anxious hypochondriac suffering from appendicitis was operated on by M. Picqué, the appendix successfully removed, and with it all the hypochondria. He remained well, and yet in his clinical history, as recently told at the Société de Médecine de Paris, there was nothing to show the connection between the removal of the appendix and the cure of the mental disease. On the same occasion M. Christian mentioned that an insane patient on whom he performed an operation for a strangulated hernia, recovered his senses after the operation. In both cases the bowel lesion had supervened after the mental disease. M. Picqué in a case of renal disease operated on a patient suffering from hypochondria, and the patient recovered from his mental disease. Of 132 cases in which operations were performed on patients suffering from chronic insanity for reasons other than treatment of their mental condition collected by M. Glenard, the mental disease was cured in fifty-one cases, in twenty-one the mental condition was improved, in forty-two no permanent benefit followed, and in five the patients died. In the great majority in which benefit thus followed on the performance of an operation, this resulted when some portion of the alimentary tract or the liver was the part affected, from which some conclude, with Esquirol, that the mental trouble had its origin in some altered condition of the alimentary system—something bringing about mal-nutrition of the nerve centres—the copro-psychiatry of the old authors, which they ascribed to fæcal accumulation in the transverse and descending colon. Guesses at truth are very unsatisfactory, but they tell of a desire to attain truth, and so far commend themselves. We wish we could better than guess at the curative effects of the operations referred to—they are deeply interesting, they show a correlation, so far our knowledge extends. It is enough to stimulate inquiry, but not enough to even start an hypothesis. He who will find the connection between the two will confer a blessing on humanity.

A NEW THEORY OF URÆMIA.

THE pathology of the condition to which *en bloc* the term uræmia is applied, remains very obscure in spite of numerous hypotheses and speculations based on the results of necessarily more or less limited and imperfect researches. Uræmia is generally assumed to be the organic manifestation of functional failure on the part of the kidney, in other words, a disease consequent upon, and directly due to, defective elimination. Nevertheless, physiologists and pathologists are by no means agreed as to the nature and significance of the body or bodies alleged to be retained; indeed, the assumption does not reach higher than mere surmise. It may be conceded that renal insufficiency is the prime factor in the production of the symptoms collectively de-

scribed as uræmia, but it must not be forgotten that renal inadequacy may apply to and explain two very different forms of functional disturbance. The trend of modern research has been to confirm Brown-Séquard's contention in favour of all organs possessing an internal secretion, even in respect of so distinctly an excretory organ as the kidney. The possibility therefore suggests itself that inadequacy of the internal secretion of the kidney may in whole or in part explain the symptomatology of this affection. In support of the existence of an internal renal secretion, Rose Bradford instanced the curious fact that partial removal of the kidney in animals does not necessarily cause any marked modification in the quantity and quality of the urine, yet, in spite of the normal excretion of urea, a marked increase is noted in the proportion of nitrogenous extractives contained in the muscles, from which he infers that the diminution in the quantity of internal renal secretion favours exaggerated disintegration of the muscle substance and perhaps of other tissues. In another direction it has been shown that the injection of dilute solutions of renal substance markedly prolongs life in artificially induced uræmia, and the same effect is produced by the injection of normal blood, and especially of blood from the renal vein. These experiments would appear to justify the assumption that the kidney elaborates and passes into the blood some substance which acts as an antitoxin to some other substance or substances as yet unidentified, the harmful effects of the latter being due to their stimulating effect on tissue metabolism, *e.g.*, waste. The data at our command are not yet sufficiently precise to enable any practical scheme of treating uræmia on these lines to be formulated, but it is well within the scope of possibility that means may be found of averting this, the outcome of renal inadequacy, in the same way and on the same principles as in the treatment of myxœdema, by the methodical administration of thyroid substance.

Notes on Current Topics.

The Influence of Maternal Inebriety on the Offspring.

THE pernicious influence on the offspring of habitual parental inebriety is a well-recognised factor in pathology and statistics seem to show that this cause is vastly more operative when, of the two parents, the mother is the sinner. This indeed is only what one would anticipate, seeing that for nine months the fœtus remains exposed to the baneful influence of the alcohol, taken persistently. Sobriety on the part of the father has but little effect so far as the health and vitality of the child is concerned, and in presence of maternal drunkenness may almost be discarded, although no doubt the result of two bad strains would intensify the consequent mischief. The influence of chronic parental inebriety in this connection bears mainly

on the higher departments of the nervous system, producing more or less marked intellectual inferiority and a functional incapacity on the part of what may be described generally as the moral functions of the brain. For instance, the children of drunken mothers have but an imperfect conception of the moral obligation of truth, in spite of careful training which, by the way, they do not usually get. Their emotions and passions cannot be brought under adequate control, consequently they furnish a large contingent to the criminal, and to what the criminologist would call the irresponsible classes. Looked at from this point of view it becomes obvious that criminal tendencies are of the nature of a constitutional disease to be dealt with preventively and therapeutically rather than vindictively.

Instruction in Hygiene.

If we wish to educate the public out of certain hygienically-detestable habits potentially harmful to the individual and inimical to the public health, it is obviously of the greatest importance to start with the young, because fundamental principles of this kind are best grasped and retained at a stage of life anterior to the formation of the habits in question. For instance, children should be taught to abhor the practice of spitting, whether on a slate, on a fellow scholar, or on the pavement. With a little perseverance it would not be difficult to induce them to refrain from putting their fingers into their mouths, or picking their noses. By dissuading them from moistening the fingers with saliva in order to facilitate the turning over of the leaves of books, sundry distressing exhibitions in later life would be averted, for it is little short of painful to the cleanly-minded to see people deliberately lick their palms before applying them to the page that has just been scanned. By teaching the young that the mouth should be reserved for food and drink, they, when grown up, will not convert their lips into pincushions or ostentatiously run their tongues over the pencil before recording memoranda, all these being practices which are more honoured in the breach than in the observance. The gospel of cleanliness should always be given a foremost place in the training of the young, for not only do they directly profit thereby, but the example which they set is calculated to be followed by their elders, whose omission in this respect becomes uncomfortably conspicuous by contrast. We commend these suggestions to those in charge of children as something to go on with, but we have by no means exhausted the subject.

The Surgical Treatment of Cirrhosis of the Liver.

THE surgical treatment of cirrhosis of the liver is a subject of perennial interest of which investigators seem never to tire. In a recent number of the *New York Medical News*, Dr. Emerson Brewer records five cases on which he himself has operated, with one recovery. In a table accompanying the paper the

author gives particulars of fifty-nine cases which have been operated on, with twenty-two deaths and thirty-seven recoveries. Many of these have never been published before, but have been obtained by the writer by personal communication. An examination of the thirty-seven cases which recovered shows that eleven cases were cured, eleven improved, fifteen not improved, and of three there is no after history. Of the eleven cases reported cured, six had no ascites two years afterwards, four lived upwards of six months, and of one there is no after history. Of the five cases operated on by Dr. Brewer himself, four died and one recovered; the condition of this patient was improved, but he had, however, to be tapped twice in the three months succeeding operation. The records of these cases are not at first sight very encouraging for the operation, but it must be remembered that in uncomplicated cases of cirrhosis of the liver the occurrence of ascites is of the gravest prognostic importance, the average duration of life being only about eight weeks after the first tapping. In only two of the cases in Dr. Brewer's table which are reported as being well after two years is it stated that they were uncomplicated by either peritonitis or perihepatitis. Dr. Brewer is of opinion that if operation is undertaken at an earlier and more favourable stage of the disease, later statistics will show a substantial improvement over those at present shown. It would appear, however, that the most favourable cases for operation are those which are complicated, as so many are, by peritonitis, either simple or tuberculous. Diagnosis of the uncomplicated disease can rarely be made before the occurrence of ascites, and then probably it is too late to do much good to the patient.

Dispensing in Hospitals.

ATTENTION has recently been drawn by the Council of the Pharmaceutical Society of Ireland to what they consider the lax manner in which the compounding and dispensing of medicine is carried on in hospitals. They "regret to know" that medicines are compounded by students, nurses, and other unqualified persons, and that regrettable accidents have been the result. They point out that it is important to have medicines compounded and dispensed by "duly qualified pharmaceutical chemists, and by licentiates of the Apothecaries Hall." They further draw attention to the extreme danger of the practice of supplying poisonous liniments, &c., in common bottles. The Council of the Society have performed a very proper duty in calling attention to these errors, which have been allowed to persist in some hospitals from one generation to another. It is not proper, or wise, that any hospital should be without a qualified dispenser, and, if possible, a resident dispenser, unless there is a qualified medical man whose duty it is to compound and dispense. And it is certainly most wrong that a dangerous liniment should be given to a patient in an old beer bottle. Of course, the root of the evil is want of funds.

Small hospitals cannot afford to pay for a qualified dispenser, and few hospitals, large or small, care to undertake the duty of providing out-patients with bottles for their medicines and liniments. It should, however, be a rule that poisons will not be supplied unless the recipient is provided with a proper poison bottle of a recognised shape. Surely, however, a duly-qualified medical practitioner is legally capable of dispensing and compounding medicines? Why, then, should he, unless he is a L.A.H., be excluded from the Council's list of persons who, one would gather, are apparently alone entitled to compound?

Illegal Cellar Dwellings.

FROM time to time the proceedings of the Coroners Courts reveal unexplored, unplumbed depths of degradation and of maladministration in our social environment. The housing problem in our great towns has by degrees attained the position of a "burning" question, but as yet the evil remains barely touched in many parts of the United Kingdom. Short of legislation, however, there is no doubt whatever that a great deal might be done to reduce the evil by a proper enforcement of existing powers. For instance, in any properly administered district no cellar dwellings should be allowed to exist. A week ago, at an inquest in Shoreditch, it was shown that a widow, fifty-nine years of age, together with a granddaughter of fifteen years, lived in what one of the witnesses described as a coal-cellar, for the privilege of using which she paid the landlord four shillings and sixpence weekly. The coroner's officer described the tenement as an underground place, reached by going downstairs from the front garden. The coroner remarked that it was not lawful to let such a place, whereupon a juror observed that the law dealing with such rooms was not often enforced in that parish. What is to be done in the case of local authorities who neglect their duty in such matters? This incident took place, be it noted, in a district where they are adverse to vaccination on the ground that improved sanitation does away with small-pox. If that be so surely it should do away with cellar dwellings first. The only way to administer a district satisfactorily from a sanitary point of view is to have efficient and frequent house-to-house inspection. Such a course would entail the necessity of a large staff of sanitary inspectors, but all improved health for the community must be paid for by a corresponding premium.

The Marriage of Consumptives.

THE whole tendency of modern treatment of phthisis is to bolster up tuberculous individuals. So far as the humaner feelings are concerned there is little to be said, for sentiment will probably never be ousted from the scheme of practical politics. All the same it is open to question whether in some points we have not got the wrong end of the stick. Why should tuberculous persons be allowed to marry and bring into the world offspring with tendencies that are almost certain sooner or later to render them a burden to society? Would it not be more logical,

as well as in reality kinder, to forbid such marriages? Legislation is, of course, a drastic remedy, but nevertheless it is invoked in almost every one of man's relationships to the complex system of modern social life. The only argument of any weight that can be advanced, as a rule, against the protection of the race by forbidding marriage to the phthisical is the fact that brilliant mental qualities are often found in families affected in that way. But, as pointed out recently by a writer in the *Saturday Review*, many other families produce men and women who are as vigorous in their brains as they are muscular, large-limbed, and athletic in their bodies. It is tolerably clear that no breeder would be content to produce stock high-mettled and intelligent, that was, nevertheless, so weak as to be knocked up readily upon any exertion, and to be prone to disease of all kinds. When that stage of philosophy is reached in the United Kingdom which will enable us to breed men and women on scientific principles then we shall exact a higher standard of health from candidates for the marriage state.

The Vaccination Problem in Chicago.

WE fear that the ignorant public are too often inclined to look on the great metropolis of the Western States of the U.S.A. as a city of pork butchers and public-houses. But such a picture of this rapidly-growing city is anything but accurate. The Corporation and the citizens have year by year taken the most enlightened views on public health, and carried out most extensive and very costly sanitary schemes. Its park system measures some thirty-five miles. Its public library is the third in extent in the U.S.A. In such a city it need not therefore create any surprise that the children at school and the citizens generally are carefully instructed in the value of vaccination as a prophylactic of variola. The Department of Health publishes a creed which cuts the ground absolutely from the feet of the anti-vaccinator, and Dr. Reynolds, the Health Officer, supplemented this creed by the following statement, which was distributed broadcast over the city:—"Not one of the 340 cases of small-pox discovered in Chicago within the last three years was found vaccinated as defined in the vaccination creed." We commend this good example of an enlightened supervision of the public health. It is but one of the many useful steps taken by the Corporation of the city, but it is sufficient to show that we may occasionally find an example worth copying in Chicago if we take the trouble to look for it.

Leprosy in South Africa.

MR. JONATHAN HUTCHINSON has returned from South Africa, whither he betook himself some months since, for the purpose of studying *in loco* the probable causes of the prevalence of leprosy in that country. He found that the disease is very sparingly distributed over the whole of South Africa, and is nowhere very abundant, and it affects principally

the coloured races. Mr. Hutchinson surmises that it was probably a new disease when first recognised in Cape Town some 150 years ago, since which time it has gradually extended over the whole British territory. The principal point of interest in these observations is the confirmation which Mr. Hutchinson has found of his theory that leprosy is due to the consumption of badly-cured salt fish, although he is constrained to admit that the evidence is in favour of the disease being sometimes communicated from man to man, not however by direct contagion, but by the consumption of food contaminated by manipulation by leprosy persons. Inasmuch as this method of transmission is only possible under cover of the grossest hygienic neglect, its spread mainly among the native races is explained. The conclusions formulated by Mr. Hutchinson are in favour of legislative control of fish-curing establishments, the education of the public as to the methods of transmission, and the establishment of small leper homes, into which the victims of the disease should be induced to go during the infective period.

Germany and the Arrest of Consumption.

OUR German cousins are rightly desirous of maintaining their pioneer position in relation to the establishment of sanatoria for the phthisical. The recent discussion in the Reichstag has shown that they are endeavouring to provide three kinds of institutions for the consumptive—sanatoria for the cure of early cases, homes for the incurable and dying, and establishments for patients who are still capable of repair, but for whom special occupations must be found which shall be less injurious than those in which they have been engaged. But towards this beneficent scheme the Government propose to vote only a meagre £7,500. We are afraid the Fatherland will make but slow progress if no greater sacrifice than this is to be made. Meanwhile, it is necessary that we, while providing sanatoria for the cure of the curable, should prevent as far as possible further spread by immediately affording facilities for the due care of the incurable and dangerously infective cases.

Eastbourne Guardian and Medical Officer

EASTBOURNE has become notorious by reason of the obstinacy and determination of the anti-vaccinationist faction in its local governing bodies. It may be doubted, however, whether the history of the whole movement in the United Kingdom could furnish a more glaring instance of illegal action on the part of those objectors whom most reasonable citizens regard as misguided persons. It appears from the report of a meeting of the local Board of Guardians published in the *Sussex Daily News* of the 24th ult. that a formal letter was read from the medical officer, Dr. J. Adams. The gist of his communication was a forcible protest against the action of a guardian, one Mr. Luck, who attended while the medical officer was vaccinating five casual paupers in the casual ward. According to the statement in the

letter Mr. Luck spoke to the medical officer in language that was "most insolent and offensive," saying, among other things, that he was worse than a criminal, and that many people had been sent to prison for a less offence. The truth of these statements appears to have been admitted by Mr. Luck, who further said he was prepared to meet Dr. Adams publicly at any time, and would give £10 to the Lifeboat Institution if the latter could justify vaccination. Some of the guardians expressed the extraordinary wish that the disputants should fight the matter out in the Town Hall. Fortunately saner counsels prevailed, and a letter of regret for the occurrence was sent to the medical officer. It is clear that official Poor-law administration would soon become chaotic if guardians were allowed in an individual capacity to interfere with the discharge of duties by their officers. The Local Government Board may be trusted to deal with the serious offence of this truculent Eastbourne guardian in a way that will prevent the possibility of the repetition of so undesirable an incident.

Traumatic Mental Alienation.

MR. HERBERT PAGE, in his luminous address as newly-elected President of the Neurological Society, dealt with the time-worn but ever-important subject of concussion of the brain, and among many suggestive and serviceable points insisted on the fact that mental derangement might result from brain injury long after the receipt of the trauma, processes being initiated by a comparatively insignificant hæmorrhage or minute cortical injury, which in their nature and extent might prove disastrous to the mental stability of the patient. The whole question is a very difficult one, concerning which much difference of opinion exists; but we understand Mr. Page to advocate a more frequent resort to early surgical interference in head injuries, so that later cerebral troubles may be avoided and the chance of mental enfeeblement rendered more distant. But has surgical trauma no deleterious remote effects? Collective evidence is needed on this matter.

Infirmiry Visits and Workmen's Compensation Acts.

THE Committee of the Bolton Infirmary have adopted a strong attitude with regard to the right of employes to obtain a medical report of patients resident in that institution. It is stated that a medical man wished to make an examination of a sick person in the wards in view of possible legal proceedings under the Workmen's Compensation Act. The refusal of the Committee to permit that course is said to have been based upon the contention that their sole duty is towards their patients, irrespective of litigation, and they object to them being worried, and their recovery possibly retarded by examinations outside those made by the Infirmary staff. Bolton is a busy manufacturing centre, and the question has been taken up warmly both by employers and by workmen. Speaking generally, it seems to us that the Committee might just as reasonably object to

the visits of police inspectors or magistrates to patients under their care. What can be gained by refusing to allow employers to obtain evidence where-with to protect themselves from fraudulent claims? If the patient be seriously ill, then it clearly would be within the ordinary duty of the medical staff of the Infirmary to forbid all visits save those of friends. Besides, the refusal to allow the attendance of representatives of legal gentlemen on one side would surely have to be extended to the other, and in that way workmen might find themselves seriously handicapped in the prosecution of a just claim for compensation. It is difficult to see how any Committee could refuse the attendance of medical men for the purpose of special reports.

Spectacles for our Soldiers.

THE great drain upon our small army, due to the prolonged campaign in South Africa, is likely to lead to far-reaching results in our military administration. The physical standard of recruits has been reduced, for one thing, and there really seems no particular reason why a short man should not make as good a modern soldier as a tall one, provided he be sound in wind and limb. Another reasonable reform has been recently promulgated in an Order issued from the War Office permitting in future both officers and men to wear spectacles or glasses on or off duty. The regulation appears to be meant for the benefit of soldiers already in the service who may be suffering from slight defects of vision, and not to apply to those first entering the army. The use of eye-glasses has been permitted in the case of officers time out of mind, thereby admitting the thin end of the wedge. In the case of soldiers in the ranks the aid of glasses would, in slight errors of vision, enormously increase their powers of accurate shooting at long ranges. Suppose a couple of men to be holding a fortified position, it would not much matter if, say, twenty per cent. of them wore spectacles; at point-blank ranges the most myopic man would probably shoot as well as one with acute normal vision. Of course, there is a certain drawback if the spectacles are wanted in wet weather, or if they be damaged or lost when wanted. These disadvantages, however, are not absolutely insurmountable. Many of the finest shots at Wimbledon and Bisley have always used spectacles. A score of Queen's Prize volunteers in spectacles would be worth more to an officer in a tight corner than ten times the number of valiant long-sighted men who were indifferent rifle shots.

Small-pox in London.

THE total number of patients under treatment showed a small decrease towards the end of last week, but there can be no hope that the epidemic has yet reached its climax. On Tuesday, the 25th, there were 42 fresh cases; on Wednesday, 47; on Thursday, 54; on Friday, 36; on Sunday, 37. The Local Government Board have taken a decisive step with regard to guardians who do not enforce the Vaccination Act by dismissing two vaccination officers in St. Pancras. The ground of dismissal was that the

officers in question took no proceedings against defaulters until a finance and vaccination committee issued instructions, which were carried out with great slackness. The position of vaccination officers in districts where the guardians are of anti-vaccinationist tendencies is therefore not altogether desirable. In various towns and villages near London the usual Easter fairs and other holiday gatherings have been put a stop to on account of the small-pox in the Metropolis.

An Ex-Lawyer and his Brass Plate.

THE Incorporated Law Society protects the legal profession against unqualified practice of the law with vigilance and rigour that are no less unceasing than commendable. It has also taken care to secure such legislation at its back as to render prosecution of offenders a simple and easy matter. In both these important functions it sets an example to an analogous body, the General Medical Council, which affords medical men no protection against unqualified practice, and which makes no attempt to secure sound legislation. A good example of the alertness and efficiency of the Law Society was recently furnished in a London police-court, where a solicitor whose name had been struck off the rolls was prosecuted on two charges. The first, that of having acted as a solicitor, was dismissed by the magistrate on the ground that no charge had been made for the service in question. The second, that of displaying a professional brass plate, was held to have been proved, and a fine of £5 and costs promptly imposed. Why should not the General Medical Council procure powers from Parliament to prosecute men displaying a brass plate after having been struck off the *Register*? As things go such offenders may, and do, keep up their name-plates, and in some cases carry on a flourishing practice in a fashionable town quarter. A proceeding of that kind reduces the penal action of the Council to little short of a farce. Why, again, should not the Council obtain, or at any rate, make a strong bid towards obtaining, powers to prosecute unqualified practice? Such a step would be not less in the interest of the public than the suppression of unlicensed legal practitioners. The real key to the supineness of the General Medical Council probably lies in the fact that it is not an elected body, and is therefore irresponsible to general professional opinion.

The Corporation Grant to Dublin Hospitals.

AN attempt has been recently made, by certain members of the Corporation of Dublin, to diminish to a considerable extent the annual grant which is given by this body to the different Dublin hospitals. The reason given for such a proposal was the old one of the necessity for diminishing the rates. We learn that the proposed change, whilst it would have interfered to a very considerable extent with the resources of the hospitals, would have lowered the

rates by just a halfpenny in the pound. Such a reduction does not appear to us to be sufficient grounds for an attempt to curtail one of the recognised charities of the City, and we are pleased to be able to state that the attempt at reduction was unsuccessful. If we were a journal which dealt with such matters we fancy we could suggest other and more material methods of improving the financial conditions of Dublin. But, as we are not, we shall not enter debateable ground. One point we might suggest to the City Fathers, which, if adopted, would possibly lead to a saving in the grant to the hospitals. Let it be understood that no hospital will receive a grant which does not make good use of it, that is, which does not by every means in its power attempt to put down the abuse of hospital relief by persons able to pay for medical treatment.

Fatigue in Neurasthenia.

THE central point in the diagnosis of neurasthenia is the symptom fatigue. This symptom is not altogether easy to define, because its manifestations vary *ad infinitum*, but it may roughly be said to consist in fatigue upon exertion which would cause no analogous sensation in the ordinary individual, allowance being made for comparative muscular development, &c. Sometimes so marked as to render all movement a source of distress, in less severe cases it may not do more than produce indisposition to exertion, a fairly common phenomenon among town dwellers. The fatigue symptom may involve the sensory side of the nervous system as well as the motor, and there results a variable degree of mental incapacity, especially in the direction of the concentration of ideas, of what may be termed the "accommodation" of the mind on near objects. This gives rise to what is often mistaken for failure of memory, though it is not really a failure but a delay in this function. The pains of which neurasthenic patients complain are in reality fatigue sensations, induced by a minimum of exertion and most marked in the muscles of the back, which are called into play under almost any circumstances.

Typhoid Fever in Syphilitic Subjects.

IT has been stated, and the statement is re-edited by Lieutenant-Colonel F. J. Lambkin, R.A.M.C., that syphilitised persons succumb to typhoid fever in a much larger proportion than others, a circumstance which, according to Surgeon Fowler, R.N., "cannot cause surprise." But it does come as a surprise and we should require very conclusive evidence in support of this statement before we could receive it as a fact. Of course if syphilis be allowed to run its course untreated, with the result of seriously deteriorating the victim's general health, any intercurrent disease may be expected to run a more severe course, but under ordinary circumstances there is no obvious reason why the existence of syphilis should either predispose to, or aggravate the course of, an attack of enteric fever. On the contrary there are plausible reasons for supposing that a patient under the influence of mercury would be

less susceptible to zymotic disease, but the data available are not sufficient to carry this supposition further. It has repeatedly been stated that an attack of intercurrent typhoid fever has "cured" a pre-existing syphilis, but the instances on record are not numerous enough to command acceptance owing to the possibility of errors of diagnosis.

The Army Nursing Reserve.

A MOST gratifying success has attended the development of her Royal Highness Princess Christian's Army Nursing Service Reserve. As originally formed, the scheme was to supply a body of well-trained nurses who would be available for the army in time of peace, and capable of being augmented to the necessary strength in time of war. The conditions of admission were, from the first, so carefully regulated as to render membership a definite and honourable distinction. The limits of age were originally fixed between twenty-five and thirty-five years, but an extension to forty years has been made during the war, "with especial reference to the occupancy of positions of unusual trust and responsibility." Up to September last the claims of nearly 1,500 candidates for service in South Africa had been investigated, and of that number about 73 per cent. were accepted. Of those chosen nearly 800 went to the seat of war, and 200 at military stations at home. There have been sixteen deaths, fourteen of which took place in South Africa. The foresight of her Royal Highness has thus resulted in providing the army authorities with a thoroughly trained and trustworthy force in time of war. So far as the failure of the Army Medical hospital administration in the war has been concerned, it cannot be ascribed to the quality of the nurses. Both army surgeons and nurses were skilled and competent enough, but were wholly inadequate in point of numbers, and hopelessly handicapped by want of the necessary special supplies, to say nothing of an orderly service that has not yet emerged creditably from the ordeal of inquiry. Princess Christian has certainly smoothed the way for an incompetent War Office in the organisation of a system of army nursing.

The Prevention of Vomiting after Anæsthetisation.

THE distressing nausea and vomiting which so often follow the induction of anæsthesia are due, it is believed, to the elimination of the drug through the gastric mucous membrane, and the late Dr. Hess, of New York, pointed out that they can be averted, or at any rate minimised, in ether administration, by giving the patient water to drink before commencing the administration, water being a solvent of ether. It is also of importance to reduce as far as possible the amount of the drug employed, quantity being a powerful factor in determining subsequent nausea. It has elsewhere been noted that the employment of a regulating inhaler which necessitates the use of but a fraction of the usual quanti-

ties has a very beneficial influence in respect of the tendency to the production of vomiting.

PERSONAL.

THE Duke of Westminster has given £500 to the Belgrave Hospital for Children, Pimlico, for which institution a new hospital is now being built on a site at Kennington.

MR. ROBERT IRVINE, of Royston, whose death took place last Thursday, has bequeathed to Edinburgh University, to found a professorship of bacteriology, a sum which it is understood will amount to £30,000.

PROFESSOR VIRCHOW is at last able to walk forth, and his first visit was to his Pathological Museum, where he received an enthusiastic reception from the assembled professors and students. The eminent pathologist is reported to be rather lame, but is in other respects in excellent health.

WE regret to learn that Dr. Alexander, of Liverpool, met with an accident when cycling on the London coach road, beyond the Valley, near Holyhead. He was pitched over the handle bar of his machine and alighted on his head. We are glad to know that his injuries are not serious.

DR. D. F. D. TURNER, F.R.C.P. Ed., has been appointed Examiner in Experimental Physics to the University of Edinburgh, this being the first occasion on which the importance of having an examiner who has received a medical training to examine medical students in physics has been officially recognised.

THE trustees of the late Miss Olivia Atherton, of Everton, Liverpool, who died a year ago, have just allocated the residue of her estate, amounting to £20,250, to Liverpool charities. Among these the Royal Infirmary, David Lewis's Northern Hospital, the Southern Hospital, and Liverpool Country Hospital for Chronic Diseases each gets £1,000.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

BACTERIOLOGICAL EXAMINATION OF MORBID SPECIMENS IN EDINBURGH.

ALLUSION has been already made in this column to the proposal which has been before the municipal authorities as to the transference of the reporting on tuberculous sputa, &c., from the laboratory of the College of Physicians to the Usher Institute of Public Health. When the change was mooted a meeting of the medical practitioners of Edinburgh was convened by the Presidents of the two Royal Colleges, and this meeting without a dissentient voice, expressed their confidence in the present system, and the hope that the town would continue, as heretofore, to have these examinations made in the laboratory of the College of Physicians. The Public Health Committee of the Town Council, a body which is naturally in closer touch with the medical profession than is the general body of the Council, considered the rival claims of the two institutions, and decided to recommend that no change be made, but that the town continue to pay a fee of from 2s. 6d. to 3s. for each specimen reported on by the College of Physicians. When the recommendation came before the Council, however, the City Fathers, by a considerable majority, decided that the claims of the

Usher Institute were paramount, and that this body should in future do the town's reporting at a cost of about £360 per annum for 1,000 specimens examined. The committee of the Usher Institute propose to set apart three rooms for the city's work, and to appoint a qualified assistant to undertake the reporting under the supervision of the Professor of Public Health, who is to be responsible to the city for its proper performance. The work is to include bacteriological examinations required by the medical officer of health in ordinary cases of infectious disease, including reporting on specimens from cases of tuberculous diphtheria and typhoid, and also similar examinations as required by the sanitary inspector, such as the examination of water, milk, foods, &c. It appears that certain of the councillors were ill-informed as to the exact state of matters, because the statement was made, and allowed to pass unchallenged, that the proposed change had the unanimous support of the doctors in Edinburgh, which is assuredly not the case. The council appear to have been greatly influenced in coming to a decision by the expressed wish of the donor, Sir John Usher, that the Institute which bears his name should provide accommodation for carrying out scientific work in connection with the Municipal Public Health department; and secondly, by the undoubted fact that the Usher institute would undertake the bacteriological examination of food stuffs, &c., which the College of Physicians laboratory does not at present make. As a consequence of the decision come to by the Town Council a second meeting of medical practitioners was held under the auspices of the local branch of the British Medical Association, at which practically the same resolutions were passed as previously, and a deputation, consisting of Drs. G. A. Gibson, Norman Walker, Miller, Ritchie, Mackenzie Johnston, Dewar and Kennedy, was appointed to lay the views of the meeting before the Council when the time came for confirmation of the minutes. The deputation repeated the arguments which are familiar to everyone interested in the matter—that the work is at present being done efficiently and cheaply, and to the complete satisfaction of the medical men in town, and that the Usher Institute is primarily a teaching institution, and not adapted for routine reporting work. The disapproval of the minute was moved by the convener of the Public Health Committee, who incidentally mentioned that there had never been any definite proposal to start a municipal laboratory (which would obviously be a satisfactory solution of the difficulty), but the former decision of the Council was adhered to, this time, however, by a majority of only three votes—very considerably less than previously. The question will come up for final decision at a future meeting, when there is reason to hope that the majority will be reversed. It is a matter for regret rather than for surprise that a certain amount of personality should have been introduced into the discussion which followed upon the reception of the deputation. Whether the medical men of the city are right or wrong there is not the slightest doubt that they are agreed on preferring that the present arrangement, which commands their confidence, should be continued, and to compare the meeting to that of the three tailors of Tooley Street was simply a rather fatuous attempt at the *argumentum ad hominem*. An ex-Lord Provost, too, was foolish enough to imagine (*why*, he did not explain) that there was a "lot of trades unionism" in the matter. "The pen trade, the tea trade, or even the tailor trade," he is reported to have said, "is not in it." Why this gentleman should have selected the pen and tea trades as those to which the opprobrium of trades unionism should specially attach, it is difficult to say; of the tailors he is qualified to speak with authority. If the majority carry their point, no doubt the Colleges will feel the snub, but they will always have the satisfaction which pioneers must feel, since they, and they alone, instituted this work in Edinburgh, and did it ungrudgingly and gratuitously for many years.

BACTERIOLOGICAL CHAIR FOR THE UNIVERSITY OF EDINBURGH.

The late Mr. Robert Irvine, Granton, Edinburgh, has

left instructions to his trustees to set apart a portion of his estate for the foundation of such a chair. It is understood that the portion in question consists of shares in a concern with which Mr. Irvine was intimately connected, and it is his wish that his trustees should accumulate the annual interest on the stock till it reaches £30,000, and then hand this sum over to the University authorities for the purpose indicated.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

THE BRANCH ASSOCIATION DISPUTE.

A SPECIAL meeting of the Lancashire and Cheshire Branch of the British Medical Association was called for Wednesday, March 26th, in order that consideration might be given to a pamphlet, written by three members of the branch, and said to contain matter derogatory to the honour and repute of that institution. The issue of the notices calling this meeting was followed by some speculation among members of the branch as to the nature and origin of the document in question. The interest was heightened a few days later by the issue of an open letter addressed to the President of the branch by Drs. Sinclair, Scott and Stallard. This letter stated that the writers presumed that the "pamphlet" referred to in the notice of meeting was a report written by themselves as medical officers of the Southern Hospital, Manchester, to their Hospital Committee. Copies of this report had been sent to the members of the Council of the British Medical Association. The writers held that it contained nothing beyond fair and reasonable criticism of the policy adopted by the Lancashire and Cheshire branch, and that, as consideration of the matter had already been postponed by the Council of the Association, there was no reason why the branch should, at this juncture, express any opinion. They therefore declined, for the present, to take any part in the discussion of their report.

Over a hundred members attended the meeting, thirty or forty of these being gentlemen who are not in the habit of gracing the gatherings of the branch with their presence. A member rose and read, with comments, several extracts from the report under consideration. The quotations read indicated that, in the opinion of Drs. Sinclair, Scott, and Stallard, certain persons have for several years back used the local branch of the British Medical Association as a weapon with which to persecute the authorities of the Southern Hospital. This persecution had been maintained because the Hospital trains midwives, gives them certificates, and advertises its lectures to midwives in the daily Press. They advised the Hospital Committee that it was unnecessary to take much notice of the annoyance brought upon them by the performance of what they rightly or wrongly considered to be their duty. Moreover, they suggested that the persons referred to, who had lately been directing the policy of the branch, were not truly representative either of the branch as a whole, nor of the medical profession at large. The speaker then moved a vote of censure on the writers of the report, and his resolution was seconded in due form. Dr. Woodcock moved as an amendment, that the consideration of the matter be postponed, and Mr. Whitehead seconded him. Resolution and amendment were supported by a number of speakers. Those present seemed to agree that in virtue of its *abandon* and *emprossement* the effort of Dr. Brassey Brierley bore off the oratorical palm. No one apparently had seen a copy of the report in question, but shouts of "vote" rose as each speaker resumed his seat. Indeed, the speeches might just as well have been omitted, for all the effect they had on the voting. The amendment was lost, and the vote of censure was carried. A large number of those present did not vote, and many had left the room before the amendment was put to the meeting. As the assembly was dispersing something was said about a committee to write a full and complete counterblast to the defamatory report, so more informatior may shortly be forthcoming on the matter.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

"NATALITY IN GREAT BRITAIN."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The subject touched upon so briefly in your editorial note of to-day, March 26th, is of intense interest to the physiologist, the statesman and the sociologist. In referring to this—the population—question, I notice that you usually express (although not on this occasion) a doubt whether a medical paper is really the proper or the best place for its discussion. To me it seems that there exists no other proper place for free examination of all the topics which the broad question involves. I fancy, further, that you may not be quite aware of the extent to which THE MEDICAL PRESS AND CIRCULAR among medical papers is read by the class of men of science who are not members of the medical profession; and I think that this large class would be glad to see, and perhaps take part in, discussions of the kind if opportunity were afforded.

Upon solution of the population question depends the progress of Western civilisation. If the Anglo-Saxon peoples, the peoples of the British Isles and the Colonies, are going to follow the example of France, the millions of square miles of fertile lands now waiting for inhabitants in Canada, Africa, and Australasia will remain sparsely populated, and in the, historically, not far distant future will be over-run by the rapidly increasing yellow and black races.

It cannot be denied that the example of the French is being copied more and more largely by the British people, not only in these islands but in the Colonies; and the expansion of the population is becoming more and more checked by the designed and voluntary action of parents. The egoism which prompts parents to shirk the trouble and responsibility of producing and rearing offspring seems in itself a serious symptom of decadence; whilst an effective system of checking artificially the natural increase of population must act in many ways to the detriment of the nation's physical and moral standard. The French are carrying on what is really a gigantic system of artificial selection, and by ensuring to a great extent the survival of the least fit are producing a race in every way stunted and inferior. The parents need to make no effort further than necessary to provide for one or two children. Unless a girl be a hopeless cripple she is, however inferior as a potential mother, certain to have a husband found for her if her fortune is in accordance with her rank in life. The sons in like way are protected from the struggle of life; they stay at home, where the parents find an easy place for them, and they are brought up in a way which ensures a lack of all the manly qualities indispensable in an "Imperial race," qualities which, as a rule, can only be developed in those who have to fight their own way in life. For those whose motto it is, "Let us eat and drink, for to-morrow we die"; for those who ask: "What has posterity done for us?" the population question may possess no interest; it will not affect their children, it will only begin to affect seriously their grandchildren; but to thoughtful men the problems involved seem of surpassing interest. If these few not very closely reasoned sentences serve to start an instructive correspondence in your columns, the purpose with which they have been penned will be accomplished.

I am, sir, yours very truly,

A STUDENT OF SOCIOLOGY.

March 26th, 1902.

THE X-RAYS IN MEDICAL DIAGNOSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Professor Haughton's article on the medical aspects of the X-rays is admirable in many respects. The only objection that could possibly be raised by the most captious critic is that the matter, although obviously true, is not absolutely and altogether new. A glance at Walsh's well-known book, the "Röntgen Rays in Medical

Work," will show that much good work had been done in the direction of medical diagnosis at the time of the publication of the first edition. The first photograph taken from the front of the chest was one of an emphysematous lung shown by Dr. Walsh at the Röntgen Society, and in the museum at the Edinburgh meeting of the British Medical Association. The second edition of the book mentioned registered a great advance in the application of the Röntgen methods to physical diagnosis. A similar remark applies to the third edition. Professor Haughton, however, is exceedingly sparing of references in his excellent article, but must be familiar with the above work.

I am, Sir, yours truly,

Newcastle, March 30th, 1902.

ELECTRICIAN.

NEW TROCARS AND CANNULÆ FOR EMPYEMA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Messrs. Arnold and Sons, London, have made for me a set of special trocars and cannulæ for use in certain cases of empyema. They are flattened from side to side and not circular as usual in other trocars, to enable them to pass through an intercostal space with greater ease. The cannulæ are made of silver, and can be left *in situ* for ten days if necessary. The trocars are of very hard steel, and in consequence of their shape the end and the cutting edge project further than in the ordinary form. To minimise the danger to deep parts when the instrument is used, each cannula is fitted with a moveable shield, being fixed at any depth by a screw as in Durham's tracheotomy tube. The shape of the shield is similar to that of a bi-valve tracheotomy tube, but is perforated by two long slots placed in such a manner that whatever be the inclination of the ribs, the tube can be kept in position by tapes threaded through

these slots and passed straight round the chest. The set consists of three, with one handle which screws into all the trocars. The sizes are as follows:—

1. Small, $\frac{1}{8}$ in. by $\frac{1}{8}$ in. and $1\frac{1}{8}$ in. long. 2. Medium, $\frac{1}{4}$ in. by $\frac{1}{8}$ in. and $1\frac{1}{8}$ in. long. 3. Large, $\frac{1}{2}$ in. by $\frac{1}{4}$ in. and $1\frac{1}{8}$ in. long. The size of the cannulæ are inside measurements; the length is the effective length, viz., from the shield to the end of the cannula.

The chief use I have put this instrument to, and have found it act extremely well, is to drain an empyema after incision of the skin under eucaïne administered hypodermically, in those cases where the administration of a general anæsthetic is especially dangerous on account of the condition of the patient.

I am, sir, yours truly,

WILLIAM TURNER, F.R.C.S.,
Senior Assistant Surgeon, Westminster Hospital.

Medical Press Congress.

THE European Medical Press Congress will be held at Monaco from April 7th to 9th, when all European nationalities will be represented. Our Nice Correspondent says there will be an elaborate scheme of receptions and *fêtes* under the personal direction of Prince Albert of Monaco, who has signified his acceptance of the position of honorary President of the Congress.

Medical News.

The Medical Graduates' College and Polyclinic.

THE annual general meeting of the Medical Graduates' College and Polyclinic was held on the 25th ult. at the College, Chenies Street, Sir William Broadbent, the President, in the chair. The report bore witness to a steadily persistent increase in all departments of the College work, the register now including forty-one life members, 127 members, 638 subscribers, and nineteen temporary subscribers, making a total of 825, as compared with 615 in 1899, and 674 in 1900.

The Chairman, in moving the adoption of the report, said that from a practical point of view the College work of the past year had been very satisfactory. The special courses, which formed a very important part of that work, had been in greater demand, and the courses, consisting of consultations and lectures, undoubtedly filled an acknowledged want on the part of members of the medical profession, inasmuch as they were thus enabled to keep up with the progress which was so rapidly taking place in every department of medical science and practice. The Council had to acknowledge that they could give this aid only imperfectly, as they all felt the need of a large clinical hospital, with in-patient and out-patient departments, laboratories, and every organisation necessary for clinical and pathological research. Such facilities were afforded by the Governments of Continental countries, and in America by the munificence of private donors. They had themselves, therefore, to be content with a modest programme, which was governed by the means at their disposal. He expressed regret that it was necessary for the Polyclinic to appeal to the public, in order that they might replace the money expended in the foundation of the College and in part the outlay on its maintenance, but in existing circumstances they had no alternative, and hence the necessity for their annual dinner, at which Mr. Balfour made such a successful appeal last year. Mr. Jonathan Hutchinson, in seconding the motion, said the institution had a very great and legitimate claim upon the non-professional public. They were not engaged in any money-making scheme, but simply in an attempt to develop and diffuse medical knowledge for the good of the public, and for the good of the poor particularly. He urged this claim specially with relation to the special Permanent Committees of Investigation, which were practically open to the whole profession. The Committees devoted their attention to particular subjects of great importance. He believed they had already got to the bottom of one such subject, and they had recently organised two new classes—one on vaccination, the other on cancer—and he assured the benevolent public that any money given to encourage such research would be most advantageously employed (applause). The report was adopted, and the usual formal business followed.

The Cholera in Arabia.

A BULLETIN which has just been issued shows that between the 16th and 24th ult. there were 11 deaths from cholera at Medina, while between the 18th and 24th ult. 523 deaths from the disease occurred at Mecca and 17 at Jiddah. The total number of deaths since the outbreak of the epidemic is 1,129.

The 14th International Congress at Madrid.

ATTENTION is called to the fact that the present rate of exchange makes it worth while for all those who propose to attend the Madrid meeting of the International Medical Congress in April, 1903, to pay their subscriptions at once, as the value of the peseta varies from time to time, and it is now low. The necessary forms of application for membership can be obtained from the honorary secretaries of the National Committee for Great Britain and Ireland, viz., Mr. D'Aroy Power, 10a, Chandos Street, Cavendish Square, London, W., and Dr. P. Horton-Smith, 15, Upper Brook Street, Grosvenor Square, who are prepared to transmit the subscriptions to Madrid and supply receipts and cards of membership as soon as they are issued for postal orders of £1 a member. Ladies, if they accompany members, pay

6s. 8d. for their tickets, which is said to entitle them to reductions of fare on the Spanish railways (probably a useless concession for English travellers), and gives admission to the various fetes held during the congress.

National Association for the Prevention of Tuberculosis.

A MEETING of the Executive Committee of the Dublin Branch was held on Tuesday last to consider a proposition brought before it by the President of the Royal College of Physicians in reference to the establishment of a sanatorium for the treatment of consumption for the destitute poor of Dublin and its suburbs. Sir Christopher Nixon mentioned that the Sisters of Mercy had recently acquired the house and demesne of Beaumont, embracing some 110 acres, for the purpose of providing a Convalescent Home for the patients of the Mater Misericordiae Hospital, and it occurred to him to suggest that the site might be availed of to establish a sanatorium for the reception and treatment of cases of consumption among the destitute poor, who could not be treated with any hope of beneficial results in a general hospital. He further said that the Sisters undertook to take charge of the institution and nurse the patients on the following conditions:—(1) That the Sanatorium be built and fully furnished; (2) That the expenses be defrayed for the maintenance of the patients and the proper working of the Institution. Sir Christopher Nixon considered that before taking any steps in furtherance of the movement it was his duty to submit the proposal of establishing a sanatorium for consumptive patients to the Executive Committee of the Dublin branch of the National Association for the Prevention of Tuberculosis, with a view to obtaining their approval and support. The following resolutions relative to the project were passed unanimously:—“Resolved—That the Council of the Dublin Branch of the National Association for the Prevention of Tuberculosis have heard with deep interest and sympathy of the probability of the establishment of a sanatorium in the vicinity of Dublin, in which the destitute poor of the city and suburbs afflicted with pulmonary consumption may be satisfactorily treated in the early and remediable stages of that complaint.” “Resolved—That the Council are of opinion that the advantages likely to accrue to the public health from the establishment of the proposed sanatorium are of a twofold kind:—First, far-reaching benefit to the patients themselves; secondly, a widespread influence for good from an educational standpoint, patients and their families being taught how to prevent the spread of the infection of tuberculosis.”

Vaccination in Parliament.

THE domestic employed at the Houses of Parliament have recently been vaccinated “by order,” the services of the public vaccinator being requisitioned for the purpose. A “voluntary” request to the police employed there having been responded to only by about twenty constables a compulsory order was issued, in virtue of which the whole force have been revaccinated. Similar pressure has been brought to bear at most of the London clubs, restaurants, &c.

Sudden Death of a Whitworth Practitioner.

DR. JOHN K. H. SMITH, of Whitworth, near Rochdale, died suddenly last week during a professional visit. The deceased gentleman was only twenty-eight years of age.

Death under Chloroform.

A MAN, aged 50, died last week at the Oswestry Cottage Hospital while chloroform was being administered. No details are forthcoming as to the mode of administration, and the stereotyped verdict was returned.

The Mortality in Foreign Cities.

ACCORDING to official returns supplied to the Registrar-General, the death-rate of the various populations per thousand for the latest week to hand was: In Calcutta 38, Bombay 115, Madras 51, Paris 23, Brussels 18, Amsterdam 18, Copenhagen 18, Stockholm 14, Christiania 15, St. Petersburg 24, Moscow 27, Hamburg 16, Munich 18, Vienna 21, Prague 26, Buda-Pesth 19, Trieste 25, Rome 24, Venice 25, Cairo 31, Alexandria 26, New York 20, Philadelphia 23.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

METAL.—There is no objection to the use of black pins in surgical dressings. On the contrary, they are preferable because they will not rust, and can be more readily seen when they are to be removed.

T. B.—Our correspondent had better apply direct to the Colonial Office.

Dr. B. (Manchester).—The best medicine for enemata is soft soap. Enemas are much less likely to follow the use of this than when the enema is prepared, for example, with yellow soap.

S. A. O.—We do not consider the fee for the operation excessive, having regard to the means of the patient and the mileage which had to be traversed.

WANTED—A GOOD GALVANIC BATTERY.

BATTERY writes:—"Will any of your readers kindly advise me as to the best galvanic battery for medical purposes, moderate in price and serviceable?"

TU QUOQUE.—We cannot publish our correspondent's communication; abuse is not argument.

EXEQUOUS.—The matter is too trivial, in our opinion, to call for serious notice.

GAMMA.—The latest book on "Hernia" is that by Mr. McAdam Eccles, published by Messrs. Baillière, Tindall, and Cox. A new edition—the second—has appeared within the past few days.

EXPERTO CREDE.—Our correspondent has apparently misread the clause in the bond. In our opinion he is bound to submit the matter to arbitration. In any case however, we think that he had better take legal advice before acting further.

X. R.—It is open to question whether the yew is really the source of the "juice of cursed hebenon," but the poisonous character of the leaves and fruit of the tree has been well recognised for centuries. They are occasionally employed in rural districts for abortifacient purposes with varying success.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, APRIL 2ND.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Drs. Fairbairn, Williamson, Berkeley, Munro Kerr, and Amand Routh. Paper—Dr. Lewers: A case of Primary Tuberculosis of the Cervix Simulating Cancer, Treated by Vaginal Hysterectomy.

THURSDAY, APRIL 3RD.

ROENTGEN SOCIETY (20, Hanover Square, W.).—8.30 p.m. Dr. Ch. Leonard, of Philadelphia: X-ray Diagnosis of Renal Calculus (forwarded).

FRIDAY, APRIL 4TH.

BRITISH ELECTRO-THERAPEUTIC SOCIETY (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Dr. Hugh Walsham: On the Diagnosis of Thoracic Aneurysm by the X Rays illustrated by the lantern. Dr. Sequeira: On the Finest Treatment of Lupus, Rodent Ulcer, &c.; illustrative cases will be in attendance at 8.15.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.).—8.45 p.m. Discussion on Anæsthetics, to be introduced by Dr. Bellamy Gardiner.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8.30 p.m. Dr. J. Allan will read a paper on "The Treatment of Malignant Disease by Currents of High Potential and Frequency," with Notes of Cases. Dr. A. Whitfield: "A Case of Peculiar Intolerance of the External Application of Mercury." Dr. J. D. Mortimer: "Notes on 1,000 Anæsthesiations."

Appointments.

ALLAN, HECTOR, M.B., C.M.Aberd., Medical Officer of Health to the Whalley Bridge Urban District Council.

BARNES, ARTHUR STANLEY, M.D., M.R.C.P.Lond., B.Sc., Senior House Physician to the National Hospital for the Paralyzed and Epileptic.

BEHRENDT, M. R. J., L.R.C.P., L.R.C.S.Edin., Medical Officer of Health to the Scunthorpe and to the Brumby and Frodingham Urban District Councils.

BRETTON, LANCELOT M., M.R.C.S., L.R.C.P.Lond., Medical Officer and Public Vaccinator to No. 3 District of the South Stotham Union.

BULLMORE, CHARLES CECIL, L.R.C.P., L.R.C.S.Edin., L.F.P.S. Glasg., Medical Officer for the Falmouth and Truro Port Sanitary Authority.

FORBES, R., M.D.Glasg., Medical Officer of Health to the Eastwood Urban District Council.

HAMILTON, JOHN, M.D.Durh., F.R.O.S.Edin., Medical Officer of Health to the Swadlincote Urban District Council.

PARSONS, FRANCIS JOHN CRANE, L.R.C.P.Lond., M.R.C.S., L.S.A., J.P., Medical Officer of Health for the Bridgwater Urban District.

PHILLIPS, G. G., M.R.C.S., L.S.A., Medical Officer of Health to the Tickhill Urban District Council.

STEWART, THOMAS GRAINGER, M.B., Ch.B.Edin., Junior House Physician to the National Hospital for the Paralyzed and Epileptic, Bloomsbury.

TURNER, DAWSON, B.A., M.D.Edin., Examiner in Experimental Physics to Edinburgh University.

WOLFE, JAMES FRANCIS, M.B., C.M.Edin., Medical Officer to the Heavitree (Exeter) Isolation Hospital.

Vacancies.

Bridgwater Infirmary.—House Surgeon. Salary £80 a year, with board and residence. Number of beds, 42. Immediate applications to Mr. John Coombs, Honorary Secretary, Bridgwater Infirmary, Bridgwater.

Chelsea Hospital for Women, Fulham.—Pathologist. A knowledge of Bacteriology will be a recommendation. Applications to Herbert H. Jennings, Secretary.

City of London Union Infirmary.—Assistant Medical Superintendent. Salary £150 per annum, together with furnished apartments. Applications immediately to Frederick W. Crane, Clerk to the Guardians, No. 61, Bartholomew Close.

Durham County Hospital.—House Surgeon and an Assistant House Surgeon. Salary of the Senior House Surgeon £100, of the Junior £65, with board and lodging in each case. Immediate applications to Wm. E. Wilson, Secretary, 684, Saddler Street, Durham.

Essex and Colchester General Hospital.—House Surgeon. Salary £100 a year, with board, washing, and residence in the hospital. Applications to C. L. Becher, Secretary.

Folkestone Victoria Hospital.—House Surgeon. Salary £160 per annum, with board, residence, and laundry. Applications immediately to the Secretary.

Guy's Hospital.—Demonstrator of Bacteriology and Bacteriologist to the Hospital. Salary about £180 per annum. Applications to the Treasurer, the Superintendent's Office, Guy's Hospital, London Bridge, S.E.

Hospital for the Insane, The Lawn, Lincoln.—Assistant Medical Officer. Salary £100 a year. Applications to Medical Superintendent, The Lawn, Lincoln.

Leicester Infirmary.—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing. Applications to the Secretary, 24, Friar Lane, Leicester.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160 per annum; furnished apartments, attendance, light and fuel are found. Applications to Secretary, M. I. Preston, Journal Chambers, Nottingham.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Rev. Philip Lancashire, M.A., Honorary Secretary.

Royal University of Ireland.—Examiners in Surgery, Midwifery, Pathology, and Ophthalmology. Applications to the Secretaries not later than April 19th. (See Advt.)

Tottenham Hospital.—House Surgeon. Salary £50 per annum, with board, residence, and laundry. Applications to the Chairman of the Joint Committee, Tottenham Hospital, London, N.

University College, Sheffield.—Demonstrator in the Bacteriological Laboratory. Salary £150 per annum. Applications immediately.

Births.

BUNDEY.—On March 26th, at 1, Honor Oak Road, Forest Hill, the wife of H. Marchant Bunday, M.B., C.M., of a son.

EDELSTEIN.—On March 23rd, at 370, Brixton Road, London, S.W., the wife of Ernest A. Edelstein, M.B., M.A., of a son.

EVANS.—On March 23rd, at Upper Wimpole Street, London, the wife of Willmott Evans, M.D., F.R.C.S., of a son.

Marriage.

ADDISON-GRAY.—On March 25th, at Trinity Presbyterian Church, Kensington Park Road, London, Christopher Addison, M.D., F.R.C.S., youngest son of the late Robert Addison, of Stallingborough, Lincolnshire, to Isobel, youngest daughter of the late Archibald Gray, of 37, Holland Park, W., and of Mrs. Gray, St. Mary's Tower, Birnam, Perthshire.

Deaths.

BROWN.—On March 28th, at Newlands, Crawley Down, Sussex, Robert Brown, F.R.C.S., in his 82nd year.

CADDY.—On March 21st, John Turner Caddy, M.D., at Charterhouse, Lion Gate Gardens, Richmond, Surrey, aged 80.

MACKAY.—On March 29th, Easter Eve, at 2, Easton Villas, Pittville, Cheltenham, Hannah Mackay, aged 81, widow of the late Eric Mackay, M.D., of Birmingham.

PHILLIPS.—On March 19th, at Porchester Square, Francis Addison Phillips, M.R.C.S., L.R.C.P.Lond., aged 30.

Paris Clinical Lectures.

HERPES ZOSTER.

By PROF. DEBOVE,
Of the Faculty of Medicine of Paris.

I PROPOSE to discuss to-day an affection which has been the object of many different theories, having been ranked successively among cutaneous, nervous, and infectious maladies. I allude to zona. The patient, the subject of this lecture, is 45 years of age, a baker by trade, presenting no family antecedents of importance save one, viz., fifteen years ago he was the inmate of an asylum for three months for mental trouble, which, however, was probably caused by excessive drinking.

A few weeks ago he experienced pain over the back of the thorax, and two days later a number of rose-coloured patches appeared over the painful area, and these on the following day developed transparent vesicles. Thus the malady commenced by pain, the eruption following two days afterwards. It is not always that herpes zoster observes this sequence. Frequently the eruption appears without any prodroma, while in other cases malaise, shivering, fever or vomiting precede the characteristic cutaneous manifestation. Our patient suffered from nothing of the kind, and during his sojourn at the hospital he had no fever.

Ten days after the first eruption another crop of vesicles appeared, and as the pain was very great he decided to enter the hospital.

At our first examination we found that the eruption occupied the left half of the thorax, forming a zone of four fingers' breadth, commencing behind at the third or fourth lumbar vertebra and terminating midway between the umbilicus and the pubis. As usual, the eruption was unilateral, but did not correspond exactly to the course of any one nerve, an important point to which I shall revert later on: it followed the course and distribution of the lumbar and the intercostal nerves and, to some extent, the course of the large and small abdomino-genital nerves.

All the region occupied by the eruption was the seat of sharp pain, the character of which the patient was unable to define. We were unable to discover that the pain followed absolutely the course of the nerves. The pain was markedly increased by pressure, indeed, the patient could not lie on the left side, and had considerable difficulty in moving in bed.

Two days after his entry into the hospital the pain subsided, but for several days fresh vesicles continued to appear. However, after a fortnight, the patient was able to leave the hospital.

Neuralgic pain sometimes persists after the zona has disappeared, and may constitute a very serious complication. I remember having seen a patient

suffer fearfully from thoracic neuralgia following an attack of zona, and this during several years, without being able to obtain relief. I also was consulted by a lady who suffered in a similar way. These cases and others that I might mention to you prove that the prognosis of herpes is not always benign, on account of the intensity and possible persistence of the neuralgia.

Other complications may also be observed in the course of zona. A woman, *æt.* 50, was admitted to hospital for zona of the neck involving the superficial branches of the cervical plexus on the left side. The distribution of the vesicles corresponded to the branches of the superficial cervical, auricular and external occipital nerves. The patient had been six days in the hospital when facial paralysis of the left side was noticed to exist, that is to say of the region corresponding to the distribution of the zona. This paralysis had all the characters of peripheral paralysis affecting the superior branch of the facial nerve. At the end of a fortnight the woman left the hospital cured of the zona, and the facial paralysis had disappeared, but the pain corresponding to the seat of the eruption was still very severe.

Paralysis has been observed in a certain number of cases of zona. Brissaud has recorded three cases of ophthalmic zona followed by hemiplegia on the opposite side, and Raymond has also published a certain number of cases of facial paralysis.

These different cases of paralysis presented the following characters: the paralysis appeared during the first few days following the appearance of the vesicles; it was generally situated on the side corresponding to the eruption, and it was recovered from without leaving any trace.

There is no absolutely necessary connection between the seat of the eruption and the distribution of the paralysis, a fact which is exemplified in the case before us, in which the facial nerve was paralysed, while the zona appeared to be due to an affection of the superficial cervical plexus.

It is rather difficult to formulate a theory which shall explain the occurrence of this paralysis. Those who consider zona as an infective disease regard the paralysis simply as another manifestation of the infection. This leads us to discuss some of the theories which have been put forward as to the nature of herpes zoster. It has been attributed by some to an affection of the peripheral nerves, by others to an affection of the cord, and by others again to infection.

The view according to which zona is only a special form of neuralgia cannot be maintained either from an anatomical or a clinical point of view. Anatomical researches undertaken for the purpose of discovering the existence of peripheral neuritis gave negative results in the immense majority of the cases, and we may conclude that this neuritis is at any rate not invariably present.

The character of the pain is not that usually attributed to neuralgia, and it does not follow exactly the course of the nerve. For instance, the pain experienced by our patient corresponded to the zone of distribution of several nerves without observing specially the course of any one of them. We shall see farther on by what theory it is possible to explain the want of concordance between the distribution of the nerves and that of the eruption.

There are many cases of zona consecutive to traumatic lesions, but that does not prove the existence of a primary peripheral disturbance of innervation, for every nerve is composed of centripetal and centrifugal fibres; the traumatism may have acted on the former, producing an irritation of the nervous centres, which revealed itself afterwards by peripheral manifestations, viz., painful eruptions.

Zona is not due to affection of the spinal cord, but it is not improbably due to functional disturbance thereof; this hypothesis is the only one which can account for the phenomena observed more particularly as regards the distribution of the eruptive elements. For instance, the centrifugal fibres which arise in a certain region of the cord do not follow exactly the course of the same nerve, but some of these pass by certain nerve trunks and others by neighbouring trunks. Consequently, a source of irritation at any one point of the cord does not produce an eruption in the course of any one single nerve, but an eruption which is scattered over several.

Is zona due to an infection? This opinion has been sustained by my friend Landouzy, who considers zona to be an infective malady. The partisans of this theory give as their reasons the existence of concomitant general phenomena and the absence of relapses, a first attack conferring immunity just as we observe in many infective diseases.

I may remark however, that these general phenomena are far from being constant, since in many instances, as in that which is the subject of our lecture, the zona is unaccompanied by fever or any malaise beyond the pain. Further, I have met with two cases of recurrent zona.

In my opinion zona is a syndrome which may be met with under very different conditions. It may be observed after certain traumatisms, after infective diseases, such as influenza and pneumonia, also in poisoning by arsenic, lead, iodides, &c., and even in the course of uræmia, an affection of which the principal symptoms appear to be those of auto-intoxication. M. Talmon has recently insisted on a special variety—pneumonic zona, which he regards as closely related to the herpes so frequently met with in the course of that affection.

Three days after his entry into the hospital we extracted from our patient by lumbar puncture ten grammes of clear cerebro-spinal fluid, containing no cellular elements in suspension. These results are in contradiction with those recently obtained by other observers, but these divergences are easily explained if we admit that zona is not, properly speaking, a malady but a symptom observed under many different circumstances.

What is the best treatment to advise for patients suffering from zona? To relieve pain must obviously be our first object, and this we may attain by giving opium either by the mouth or by hypodermic injections of morphine.

Of late injections of cocaine into the arachnoid cavity have been advised for various painful affections, among others for sciatica and gastric pain. I confess I am not a very enthusiastic advocate of this treatment. I have treated in this way some cases of obstinate neuralgia, but I only obtained temporary relief. Lastly, the eruption must be protected against secondary infection by the application of

antiseptic powders and absorbents such as oxide of zinc bismuth, orthoform, &c.

Original Communications.

A CASE OF LITHOTRIPSY PERFORMED ON A BOY.

By DR. ALAPY HENRIK,
Professor at the University of Budapest.

IN regard to urinary calculi in adults there is no longer any question whether lithotripsy or lithotomy is the more reasonable procedure. This question is indeed already settled in such wise that every urinary calculus is, if possible, crushed, and lithotomy is performed only when, for any reason, crushing is contra-indicated. We may add that surgeons discover fewer contra-indications in proportion to their dexterity and skilfulness in performing lithotripsy.

With regard to urinary calculi in children, however, this statement does not hold good, at any rate for the present. On the contrary, childhood is regarded as the main contra-indication of litholapaxy on account of the undeveloped state of the urethra rather than by reason of its anatomical and physiological relations.

These latter differences are the following: the high position of the bladder, the absence of the prostate, and the unusual contractility of the bladder, all factors which materially enhance the difficulty of lithotripsy. It must be granted, however, that they only increase the difficulty, and do not absolutely prohibit or prevent the operation. If the calibre of the urethra of children were really as small as it is generally supposed to be, then lithotripsy could not even be attempted.

But this supposition is erroneous. The urethra of children is wider than is generally believed, and, as a rule, it is sufficiently wide to allow a free entrance for the instruments. This is proved by hundreds of performed lithotripsies published by Keegan, Freyer, Alexandrow, Denny, Barling, Guyon, Harrison, &c.

I wish to direct the attention of my colleagues particularly to one point, viz., that the average number stated by Otis regarding the connection between the circumference of the penis and the calibre of the urethra—holds true also for children, a fact of which I convinced myself by experimental researches executed both on living children and on the dead. The calibre of the urethra of children is never smaller than the size corresponding to comparative number deduced from the circumference (57 mm. circumference corresponding to 24 Charrière, 51 to 22 and so on). We may even assert that sometimes it is with from 1 to 3 numbers wider. This is a very important fact because the measurement of the penile circumference enables us (without the formerly performed violent widening of the orifice) to ascertain whether the crushing operation is practicable or not.

Various surgeons have laid down different ages for the minimum limit of lithotripsy (2 to 15). But this limitation cannot be justified, because our guide must be the state of development of the penis and urethra, and not merely the age of the child.

For instance, during the year 1899 I discovered a urinary calculus in a boy, æt. 22 months. The circumference of the penis was 4 cm. (which corresponds to 18 Charrière), and the smallest lithotrite (Collin 00) at its widest point does not exceed 15 Charrière. After dilating the meatus of the urethra I measured the urethra with bougies and found that the calibre was of No. 20 Charrière gauge. I crushed the calculus with this instrument with the greatest

case, and I obtained an excellent result. Keegan succeeded in crushing a calculus also in a child, *æt.* 18 months. Russian surgeons, again, have also successfully performed the operation on infants at the breast.

We must not conclude from these instances that in every case lithotripsy can be performed. By no means. We must always take into consideration the diameter of the urethra, the size of the calculus, and it is only when these conditions are favourable that we can successfully undertake lithotripsy. A large and hard stone cannot be crushed with a small instrument. But such stones are seldom met with in children, and therefore if the lithotrite can be passed through the urethra, the stone can be crushed.

The lad in question complained of urinary incontinence and pain on micturition. These symptoms in children are very suggestive of the presence of calculus. They are more suggestive than the sudden stoppage of the flow ("as if cut through with scissors") on which stress is laid in so many treatises. This symptom is not due to calculus but to urethro-spasm. The urine was of alkaline reaction, and with the metallic sound I felt a small calculus. Diagnosis: urinary calculus with associated cystitis. The circumference of the penis was 45 mm., accordingly the calibre of the urethra was 20 Charrière, which circumstance seemed to justify the view that lithotripsy was practicable.

After a few days litholapaxy was performed on the boy under chloroform-narcosis in the Trendelenburg posture. This posture and narcosis are indispensable to the operation in children. On washing out the bladder it became evident that the bladder contracted even after the injection of from seventy to fifty cubic centimetres of fluid. As this has to be avoided at all cost, I began the crushing in seventy cubic cms. fluid, and finished it in about thirty cubic cms. The instrument I used was Collin No. 0 lithotrite, which at its widest point does not exceed No. 20 Charrière. The calculus was two cms. in diameter. In spite of the small quantity of the washing fluid, the crushing injured the bladder so slightly that the water emptied by the after-washing showed no trace of blood. When the Guyon aspirator revealed the absence of any more gravel I again introduced the lithotrite, but I failed to find any fragments of stone.

As I had to deal with an inflamed bladder, I tied into the urethra a catheter *à demeure*. After removing this the patient was able to leave his bed on the third day.

The calculus being examined was found to consist of phosphates. With such small stones after-examination is superfluous.

The question yet remains undecided whether we are to perform the lithotripsy in every case of urinary calculus in children, or whether we ought also in some cases to perform lithotomy. This much can be stated, that the urinary calculi of children are easily removed with the lithotrite, as shown by experience.

We all know how particularly good the results of lithotomy are in children. It must be granted, too, that with the old methods we obtained excellent results with a very slight mortality. Then the question arises, why should we have recourse to the newer method of lithotripsy?

The answer is, simply, that the better is the enemy of the good. The death-rate, it is true, by both methods is small. When ascending renal infection has set in, the patient is just as likely to die after lithotomy as after lithotripsy.

Although I think that the danger of the latter is probably less than of the former, apart from unexpected complications after a skillfully performed operation no cases in children ought to have a fatal

end. In this respect there is hardly any difference between the two methods.

But there is a great difference in other respects. After lithotomy it is tolerably common for the sutured wound to fail to heal by primary union. In presence of an inflamed bladder no surgeon attempts suturing, with the result that the patient is confined to bed for weeks with persistent incontinence of urine, the tendency of which to provoke eczema is very difficult to overcome. After lithotripsy, on the other hand, the child, when conveyed from the operating table into his bed, is practically already cured. On the following day, or at most on the second day, he leaves his bed and is in a state to leave the hospital.

It is also said that lithotomy is more certain than crushing because the latter is often followed with recurrence. Working as we do in the dark, we may leave behind gravel, which form the foci of fresh concretions.

Those who assert this are probably not aware what excellent service a good aspirator can render, aided by the cystoscope, in the hands of a dexterous surgeon. This formerly-justified objection has become groundless. Lithotripsy, which compares well in regard to recurrence and death-rate, cures the patient just as certainly as lithotomy, but with less pain and in a much shorter time.

A CASE OF PLASTIC BRONCHITIS

IN A CHILD EIGHT YEARS OLD,
By HENRI DARDENNE, M.D., Edin., M.R.C.P.
London,

Physician to the French Hospital.]

In the *Lancet* of September, 1900, I published a case of "Plastic Bronchitis in a Male Adult." My excuse for publishing the present one is because it is considered by every one of us as one of the rarest affections and is still more so in children, for, in the whole of the literature, so far as I could ascertain, only four authenticated cases have been published.

Before actually relating the present case, I may perhaps be permitted to state the views held on the pathology of that disease tracing it step by step from those of the ancient authorities to those that are generally current at the present time. Nearly all the cases that have been published have been in England, Scotland and Germany.

The French physicians afterwards devoted much of their time and labour to the study of its exact pathology. Hippocrates, so far as I can ascertain, does not seem to have mentioned it in his classical works. Galen is perhaps the first one who noticed that one of his patients used to expectorate what he thought to be a branch of the pulmonary vein. Judging from his description this would appear to be nothing else than fibrinous casts.

Tulpius and Paaw, his master, and a professor of anatomy at the University of Amsterdam, were also of opinion that these casts were some branches of the pulmonary vessels. Bartholini was also of the same opinion. They were amazed at the thought, that some of their patients at times recovered, and they all looked upon it as a miracle.

It was only a considerable time afterwards that another step was made in the right direction which threw some light on the nature, the seat of their origin, and the mode of formation of these casts.

The first somewhat accurate description which attracted the notice of the medical profession was that of a man named Clarke. His letter was addressed to Dr. Sifter, and is contained in the "Philosophical Transactions," vol. 19, 1697, p. 779. The case is briefly this. A man, a tailor by occupa-

tion, had for three or four years been expectorating a large amount of semi-solid masses, which had the appearance of little worms. He used to cough a whole day, and the fit was instantly stopped after he had expectorated one.

Dr. Sifter wrote back that the little masses which appeared to Mr. Clarke as worms, were nothing else than the viscous secretions of the small bronchial glands, moulded to the bronchial ramifications, and gave them the name of bronchial polypi.

Dr. Bussiere relates also in the "Philosophical Transactions of the Year 1700-1," vol. 2, p. 545, a case of considerable importance. At the post-mortem examination he found the pulmonary vessels normal. The casts, according to him, consisted of the secretions from the tracheal glands. The secretions having been reduced to a jelly by the dryness of the outside air, had incrustated the trachea and the bronchial tubes. In that case he found a cast which extended from the larynx to the finest bronchial ramifications. He does not say whether it was in one or both lungs. From that time only they were no longer considered in this country as portions of the pulmonary vessels.

Dr. Samber, in the "Phil. Transactions" of the year 1727, p. 262, gives the description of a case, and also a very fine drawing of the casts. He is the first to mention that, by the help of his blowpipe, he succeeded in inflating the fibrinous casts.

Dr. Nichol, in a letter addressed to the President of the Royal Society ("Phil. Transactions," year 1731-2, vol. 18, p. 123), mentions the case of Nicholas Tulp (2nd Book, 7th observation). He also relates a case of his own. He compares the cast, when being floated in water, to a vein, and having, as the latter, the same tough consistency. His patient expectorated them for seven years. Some were white, others were deeply tinged with blood. He was also of opinion that they were due to the viscid secretions of the tracheal glands.

In 1802, Dr. Breeman related in the *London Medical and Physical Journal*, p. 360, the case of a sailor.

Dr. Acharin's case is also related at full length in the same journal and in the same year. The priority rests with Dr. Clarke.

Cheyne, of Edinburgh, in the *Edinburgh Medical and Surgical Journal* of the year 1808, vol. vi., p. 441, contributed a good deal to further the knowledge of this rare affection. He divided the disease into two groups: (1) pure white bronchial polypi; (2) spurious or hæmorrhagic bronchial casts.

The pure white ones were, according to him, manifestations of a very rare and curious affection. They were symptomatic of a pure chronic disease, usually preceded by catarrhal symptoms. He was of opinion that they were formed of condensed bronchial epithelium. Further knowledge in this subject has disproved his theory.

Dr. Baillie was of opinion that inflammation of the bronchial mucous membrane was not invariably present. Cheyne thought the contrary and, at the present day, Cheyne's views are the most prevalent ones.

John Hunter, in his treatise on the blood (1828) gives a very good drawing of a fibrinous cast expectorated by one of his patients.

John North (1838 *London Medical Gazette*) gives a full description of two cases.

Other cases have been published by Fuller, Salter, and more recently by Hilton Fagge ("Pathol. Trans." Vol. 21). My own case, published in the *Lancet*, of September 15th, 1900, is the most recent one, and in it I gave a full record of the post-mortem appearances.

According to the views held at the present time the casts are made up of mucus and not of fibrin.

The process is considered to be analogous to mucous colitis, and this is perhaps the correct pathology.

I will now proceed to relate briefly the history of the case: On August 25th, 1901, I was summoned by Mr. B. H. to see his child, a boy, æt. 8, who had suffered from catarrhal bronchitis for the last three days. He had previously been soaked through with rain. He was the only child, and there was nothing particular in the family history. His previous health had always been good and his surroundings excellent. On my arrival half an hour after I had been summoned by the father, I found the child suffering from intense dyspnoea, and he seemed to be on the verge of suffocation. His face was livid and covered with a cold perspiration. His eyes were bloodshot, the muscles of forced inspiration were acting powerfully, and I noticed that both hypochondriacal regions receded on inspiration. He had an incessant and most harassing cough, and this would at times be relieved by the patient's expectorating a thick mucosanguinolent fluid. His voice could scarcely be heard, and he complained of pain and of a sense of pressure in the epigastrium. His breathing was about 70 per minute, his temperature 99, and his pulse 120. On examining his chest I found the vocal fremitus and resonance deficient. On percussion the left base behind was slightly dull. Sibilant and sonorous rales were present both in front and behind. The respiratory murmur was much impaired at the left base behind, and the vocal fremitus here was slightly impaired.

All at once his face became perfectly livid, and the child gasped for breath. His whole body was shaken with a terrible fit of coughing. With considerable effort, painful to witness, he expectorated a dark mass the size of a small marble, followed immediately by about an ounce of dark semi-clotted blood. He felt at once relieved.

I had no hesitation, remembering my previous case, to diagnose it as a case of plastic bronchitis. For the next three or four days he spat some mucosanguinolent fluid. He was, however, better in every respect. The child apart from this was healthy, and there was nothing of mark to note in the other systems. The urine was free from any abnormal ingredient, and in quantity was normal.

The respiratory murmur was more distinct at the left base. On the following day the temperature was normal. Eight days afterwards he had another slight attack, again preceded by pains in the epigastrium and between the shoulder blades behind; the dyspnoea was very much less, the casts much smaller, softer and more friable. He was perfectly well three weeks afterwards, and all the catarrhal symptoms had disappeared.

NATURE OF THE CASTS.

They were either by themselves or rolled up in the form of a little cherry-stone, coated with mucosanguinolent fluid. In colour they were yellowish-brown; their ends were slightly bulbous. There were irregular bulgings on their surfaces. In consistency they were slightly compact and somewhat elastic. I could not, with the blowpipe, succeed in inflating any of them. On cross-section concentric layers of a lamellated fibrillar structure were noticed, enclosing in their fine meshes leucocytes, pus corpuscles and some cylindrical epithelium, with a few red blood corpuscles. Crystals of Charcot in this case again were not detected.

The casts were insoluble in water, but were so in lime water to a very great extent. I am now more inclined to be of the opinion that they are made up of mucus than of fibrin.

TREATMENT.

I have no hesitation to state that the atomised lime water which I gave to the patient prevented the

casts from forming again, and thus causing another paroxysm. This treatment was followed up for three weeks.

Iodide of potassium was also given during all this time added to an ordinary cough mixture.

Ruchenmeister is, I think, the first one who employed lime water in such cases, based on his personal observation of the solubility of all diphtheritic membranes in that liquid. In conclusion I may be permitted to say that plastic bronchitis is perhaps more prevalent in children than is usually thought of and more than one of the so-called cases of infectious croup which is cured by the sero-therapeutic treatment would perhaps, on careful examination, turn out to be one of plastic bronchitis. The child has, I am glad to say, never suffered from another attack, though he has continued to live in London.

RESISTANCE OF PROTOPLASM TO EXTREMES OF HEAT AND COLD. (a)

By HENRY H. DIXON, ScD.,

Assistant to the Professor of Botany, Trinity College, Dublin.

If the temperature of an amoeba is gradually raised the protoplasm composing it first passes through a stage of stimulation, when its movements are comparatively accelerated and vigorous. At a temperature of about 40° to 45° C. it falls into a state of quiescence. If it be maintained only a short time at this temperature and then cooled the normal phenomena of life reappear and it begins to creep about once more. This quiescence is a *temporary heat rigor* only. But if the amoeba is kept a considerable time at, say, 44° , or raised for a short time to 45° or higher, coagulation sets in. The protoplasm becomes somewhat opaque and rigid. From this condition it will not become reanimated on the return of a favourable temperature, but death has supervened. It is believed that coagulation is the cause of death, and at least it is very closely simultaneous with it. Of course, this is not always the case, for there are many marine animals and plants to which temperatures even below 30° are fatal. The lowest coagulation point for proteids is 40° , viz., that of *myosin*. Egg albumen coagulates first at about 50° .

Little seems to be known as to what coagulation is. Hardy, who has recently done much experimental work on colloids, regards their coagulation as a precipitation. The fact that the coagulation of protoplasm is irreversible, i.e., the restoration of previous conditions does not restore the previous state, is what is of immediate importance in these considerations.

The lower limit of temperature which protoplasm can stand without suffering death is much less clearly defined. So many factors besides the low temperature enter into all the experiments made up to the present.

For instance the rate at which normal temperatures return influences the result of exposure to low temperatures in a very marked manner. Thus a cell subjected to -10° , if it is thawed quickly, will almost certainly die, while if the rise in temperature is gradual it may revive.

To obtain comparable results other factors, too, should be considered, e.g., the amount of water in the protoplasm experimented upon. Its previous conditions must also be taken into account, for sudden changes are always more trying than gradual.

Some interesting information is, however, available regarding the lower temperature limits of protoplasm.

Many plant cells are not killed by -14° . Larval insects may resist -15° to -28° . Pictet found that a centipede which survived -50° was killed by exposure to -90° . He also found that a snail actually survived a temperature of -120° for several days.

The change undergone by protoplasm killed with cold seems to be similar to coagulation. It is thrown out of solution, or precipitated in an insoluble form.

The phenomena attending the freezing of cells are peculiar. One of the simplest things to experiment with is an ordinary potato. A freezing-point thermometer is inserted into the substance of a potato, and the whole is surrounded with a freezing mixture. The thermometer gradually falls to 0° , and then slowly goes lower till it registers a temperature of about -4 to -5° . A sudden rise now intervenes, and the mercury comes to stand opposite to -1° . At this moment the potato becomes frozen hard. Cooling now proceeds till the temperature of the freezing mixture is attained.

The peculiar behaviour of the thermometer is explained by *supercooling*. The water in the protoplasm is a solution of salts, and its freezing-point is considerably below 0° . At -4° , or so, a dilute solution, whose freezing-point is -1° is forcibly separated from the rest and congeals. The remainder has a very much lower freezing-point. It seems quite probable that it is this violent and sudden withdrawal of water and concentration of salts which is responsible for the death of the cells in a frozen potato.

Cells once frozen hard, it is believed, never survive unless they are almost completely free from water at the time of exposure.

Both the upper and lower temperature-limits may be considerably extended by acclimatisation. It is well known that sudden changes of temperature are much more injurious to an individual than gradual alterations. The same holds true for the race.

Davenport showed that by keeping the developing eggs of frogs at a high temperature the tadpoles produced can resist a higher temperature than those developed under normal conditions.

Dallinger states that by very gradually raising the temperature during successive generations he succeeded in developing from protozoa, which at first succumbed to a temperature of 23° , a race which could resist a temperature of 70° .

The acclimatisation to extremes of temperature also occurs in Nature. Organisms are found living in hot springs at a temperature of from 50° to 60° , whose near relations occurring in more normal situations would be immediately killed by such temperatures. Other less authenticated cases are on record of plants which grow in springs at 90° to 98° !

In the same way organisms may be acclimatised to low temperatures. But in this direction there are not so many experimental data to hand.

So far, however, it is known that protozoa taken in summer and subjected to low temperatures are easily killed by sudden cold which they would resist in winter.

Several theories might be advanced to account for the phenomena of acclimatisation:—

1. It might be supposed that the organism acquires a power of maintaining, by means of its metabolism, a temperature within itself which departs but inappreciably from its normal temperature, or

2. It may gradually cease to produce within its substance proteids which are injured by the extremes to which it can be acclimatised.

3. The gradual concentration of the solutions in the vacuoles of the protoplasm may be the method adopted for acclimatisation to cold.

This last theory might be easily tested by gradually increasing the concentration of the solution in

which an organism lives, and then determining if it possessed greater resistance to low temperatures.

However resistance to temperature-extremes is attained in these cases of acclimatisation, certain it is that protoplasm of many species can pass into a state which is little affected over wide limits of temperature. A well-known example of this is furnished by bacteria. Species which are killed generally by a temperature of 75° form spores which resist over 105° ; and it has been found that these spores were not injured by -180° . It is also known that seeds will often germinate after being long exposed to extremes of heat and cold which would quickly prove fatal to the plants which produced them.

This immunity to extremes can be greatly increased by desiccation. Spores which when moist are killed by 60° will, when quite dry, resist a temperature of 120° . There are actually organisms as highly developed as worms and arachnids, which if carefully desiccated will come through heat amounting to 120° without suffering injury, while if their tissues contain any appreciable amount of water 50° is fatal.

The raising of the upper extreme by desiccation is paralleled by the behaviour of desiccated egg albumen. The coagulation temperature of albumen depends upon the amount of water in it. Some idea of this may be obtained from the following figures:—

An aqueous solution of albumen coagulates at	58° C.
Albumen with 25% of water coagulates at	74° - 80°
Albumen " 18% " "	80° - 90°
Albumen " 6% " "	145°
Albumen " 0% " "	160° - 170°

Judging from the high resistance of desiccated protoplasm to extremes of temperature we might be tempted to assume that acclimatisation consisted solely in the elimination of water from it. Although, as previously explained, this process may be partially responsible for acclimatisation to low temperatures, it will not explain both forms; for if acclimatisation to both high and low temperatures were attained in this way it would follow that an organism acclimatised to cold would at the same time extend its heat limit. But what has gone before shows that the converse is the case in reality.

Last spring I made some experiments in the Botanical Laboratory, Trinity College, on various kinds of seeds to ascertain how far the upper temperature-limit might be extended. I found that plants which are killed by a temperature of 45° produce seeds which in no case suffer harm from a dry heat of 100° , while in many cases a temperature of 115° or even 121° is innocuous.

The curious fact was observed in the course of these experiments, that the higher the temperature to which the seeds had been subjected, the longer was the time needed for germination. To illustrate what I mean I will quote one example: lettuce seed sown under normal conditions will germinate in two days; if exposed to 105° it still germinates in two days. But if samples of seeds are exposed to 107° , 110° , 112° , 114° they will take respectively six, eight, twelve and eighteen days to germinate. From this it appears that though the protoplasm was not killed by these temperatures, yet it had undergone some change, and it is conceivable that if the seeds had been maintained for a much longer time at the high temperatures, this change might have progressed until ultimately the seedlings might have succumbed. Another indication of a change set up in the protoplasm by these extremely high temperatures was shown by the fact that the young seedlings grown from these seeds had to some extent lost their gravitational sense, so that they frequently grew with their roots standing up in the air, while the tops of their tiny stems turned downwards.

The state in which the protoplasm of spores and seeds is evidently, from the experiments quoted, quite different from that of ordinary protoplasm. This is evinced not only by its resistance to high temperatures but also by the suspension, or at least great diminution, of vital processes. In fact, many physiologists now regard the protoplasm in these bodies as in a state of *suspended animation*. In desiccated seeds the vital processes such as respiration and excretion are reduced to such a low minimum that they have eluded all efforts up to the present for their detection. Seeds will germinate after being kept for years in *vacuo*, or surrounded by inert gases, such as nitrogen and O_2 . Neither can delicate weighing detect any loss in their substance. In such instances of course continued respiration is impossible. Many seeds will germinate even if kept for long periods (months or years) under absolute alcohol. In this case the alcohol surrounding the seeds must prevent any appreciable interchange of gases between the protoplasm and the atmosphere. But this experiment must not be quoted, as has been done, to show that dormant protoplasm—protoplasm in a state of suspended animation—is not coagulated by alcohol. As a matter of fact the alcohol does not, even in sixteen years, penetrate the seed coat, so impervious does it become when thoroughly dried. This may be simply shown by puncturing the seed-coat with a needle before immersion in alcohol. None of the punctured and alcoholised seeds will germinate.

If the protoplasm of spores and seeds is to be regarded as really living, I think we will have to modify our ideas of life somewhat. Most of us have regarded life as a succession of changes destructive and constructive—the vital processes or metabolism. Without these changes we have been taught that life is impossible, and when once they cease in a given mass of protoplasm, it has to be worked up over again by other living protoplasm before these processes can recommence. According to these precepts the protoplasm of spores and seeds is not living. But, as subsequent tests show, it has the power of automatic reanimation, and so it differs from killed protoplasm.

That protoplasm in which all vital processes have been completely suspended, and is accordingly regarded by some as dead, can become automatically reanimated, has been conclusively proved during the last few years. Several experimenters have succeeded in raising healthy growing plants from desiccated seeds which have been kept for a considerable time at the temperatures of liquid air and liquid hydrogen. It is known that at these temperatures all chemical actions are suspended, and that consequently the chemical processes of metabolism must have ceased. Here it is not allowable to assume that some tiny spark of life was kept alight by vanishingly small, if not observable, quantities of energy, and so preserved unbroken the chain of changes called life from parent to offspring. When exposed to this low temperature all change in the protoplasm is precluded; and so, whether we like it or no, we must admit that for a time at least active life passed into dormant life to be re-awakened by the return of heat and moisture.

The Mortality in Foreign Cities.

ACCORDING to official returns supplied to the Registrar-General, the death-rate of the various populations per thousand for the latest week to hand was: In Calcutta 35, Bombay 119, Madras 48, Paris 23, Brussels 17, Amsterdam 16, Copenhagen 16, Stockholm 15, Christiania 11, St. Petersburg 26, Moscow 29, Hamburg 17, Vienna 23, Prague 24, Budapest 18, Trieste 31, Rome 21, Venice 21, Cairo 33, Alexandria 33, New York 19, Philadelphia 20.

Clinical Records.

TOTTENHAM HOSPITAL.

Case of Secondary Syphilis in a Man Affected with Psoriasis. (a)

By G. NORMAN MEACHEN, M.B., B.S. Lond.,
M.R.C.P. Edin.,

Physician to the Skin Department, Tottenham Hospital.

THE patient, a man, æt. 40, married, presented himself at the out-patients' department of the Tottenham Hospital in July, 1901, with an eruption of typical psoriasis involving chiefly the extensor surface of the limbs, the body being only very slightly affected. It was his first attack, and it began about a month ago. He had suffered from no other illnesses. The treatment consisted of creolin baths and tar ointment externally combined with the internal administration of an aperient iron mixture. His attendance at the hospital was somewhat irregular and his progress towards recovery was correspondingly slow. When seen at the end of December, 1901, his skin presented a distinctly unusual appearance. He was covered practically all over with a deep red, papular eruption, which he stated he had noticed for a week. Some of the papules, which were infiltrated to the touch, were actually superposed upon the psoriasis patches which had not yet faded, and which, besides being more scaly, were of quite a different tint to the dull red of the more recent eruption. The coincidence and superposition of the two rashes was best marked upon the extensor surfaces of the legs. The fauces were intensely congested, and mucous patches were seen upon the buccal mucous membrane. The patient acknowledged having been exposed to infection six weeks previously, and evidence of the primary lesion was not wanting. Almost as if in corroboration of the diagnosis, his wife came up to the hospital a fortnight afterwards with a typical secondary specific eruption. Both patients were at once put upon anti-syphilitic remedies with good results. In the case of the man, local anti-psoriatic treatment was still continued.

This case affords a good example of the manner in which two entirely different cutaneous diseases, varying as much in their clinical manifestations as in their pathology, may co-exist, and run their courses quite independently of each other. The association of psoriasis and syphilis does not appear to be very frequently observed in this country, but the French dermatologists state that the co-existence of the two diseases is far from rare. The localisation of papular syphilides upon psoriasis patches has been noted by Dornig and Neumann, and Nielsen, of Copenhagen, observed two cases where ulcerative syphilides appeared upon the margin of patches of psoriasis. Pye-Smith states that a patient affected with psoriasis may acquire syphilis as he may scabies. Each disease "ignores" the presence of the other, and is cured by its own appropriate treatment.

UNIQUE CASE OF FRACTURE OF BOTH BONES OF THE FOREARM ABOVE THE EPIPHYSES. (b)

By E. H. BENNETT, M.D., F.R.C.S.,
Professor of Surgery, Dublin University.

IN presenting the specimen before the Royal Academy of Medicine the author remarked that the case was a unique one, nothing even resembling it being recorded. On December 8th, 1900, he met the individual who furnished this very unusual specimen—a fracture of both bones of the forearm immediately above the epiphyses. She was a most peculiar girl, about 15 years of age, plump and well-nourished. She was densely ignorant, and strongly objected to being educated, stating that "nothing or nobody could make her know anything." A lady who knew her sent her to a training school for servants in Dublin. Whilst

in the school she fell down some steps or stairs and produced the fracture. The accident happened on December 8th, 1900, and Professor Bennett saw her that day. The deformity somewhat resembled that of a Colles' fracture, or an epiphyseal separation of the lower end of the radius. He reduced it as well as he could, but he did not do it to his satisfaction, and put it up in splints. She came the following day to his study and he found the splints all right, and she now told him that at the time of the accident she distinctly heard the bone break. After six weeks, he took off the splints and found the bones united. Be it noted that this occurred in a well-nourished, good-coloured country girl, who had not complained of any illness, and had no sign of physical weakness, except an unduly large abdomen, and, what he learned afterwards, a distaste, indeed a positive dislike to all food except dry bread, refusing to eat meat, butter, or even sweet cakes. The only occupation she could be got to fill was the folding of tablecloths into lengths for mangling. On February 10th, 1901, he was asked to examine the wrist, and to his surprise he found that the deformity had returned. He sent her to Sir Patrick Dun's Hospital and had the wrist skiagraphed. A transverse fracture of both bones, just above the epiphyseal line, was plainly marked; a cast (which was exhibited) was taken of the limb at the site of the deformity, and it had some considerable resemblance to Colles' fracture. The fracture was easily reduced and the patient left hospital on May 5th, 1901. She returned to the school, where she continued to be engaged at light work. Up to this, no other trouble than the broken wrist had been complained of. She, however, still persisted in refusing meat and all other forms of food except dry bread. She was next seen on January 1st, 1902, when Professor Bennett was shocked to find her so much changed for the worse; she was profoundly pallid, of a deeper pallor than that of chlorosis, the spleen was greatly enlarged, and there was a certain amount of ascites, and the deformity of the wrist had greatly increased. He asked Dr. Finny to take her under his charge. On February 8th she died. From the time she left Sir P. Dun's Hospital in May, 1901, the deformity of the wrist-joint had gradually, but steadily, increased. The autopsy revealed no rickety condition; there was no trace of osteomalacia, nothing telling of bone-softening. All the characteristics of pernicious anæmia were present, and, as may be seen from the specimen here exhibited, the fracture is well marked and the posterior inferior extremity of the radius ends in a convexity, which is well marked and extends to its inferior articular surface. A diligent search on the subject of fractures fails to find a similar case. The most recent books are as silent on the subject as the oldest. In scurvy, as we know, fractures do not unite, and old ones come apart; but this patient's deformity returned when she was apparently in good health.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, APRIL 2ND, 1902.

PETER HORROCKS, M.D., President, in the Chair.

TUBERCULOSIS OF THE UTERUS.

SPECIMENS of tuberculosis of the uterus were shown by Dr. H. R. Andrews, Dr. H. Williamson, Mr. J. H. Targett, Mr. E. O. Croft (Leeds), and the President, after which Dr. A. H. N. LEWERS read a paper on

A CASE OF PRIMARY TUBERCULOSIS OF THE CERVIX SIMULATING CANCER, AND TREATED BY VAGINAL HYSTERECTOMY.

The patient was a married woman, æt. 36, who had never been pregnant. For nine months before she came under observation there had been a vaginal discharge, which was blood-stained and slightly offensive. Bleeding had been noticed after coitus, and also after using a vaginal syringe. She had had slight pain in the left iliac region for about five months

(a) Exhibited before the North-East London Clinical Society, February 6th, 1902.

(b) Specimen shown and Notes read before the Royal Academy of Medicine, March 31st, 1901.

This did not appear to have been at all severe. The catamenia had been regular, lasting three or four days only, and not attended by any special pain. The patient's general health had been good up till twelve months before she came under observation. Then she found herself beginning to get weak and disinclined for exertion, and to suffer from the local symptoms above mentioned. She did not think she had lost flesh. One of her aunts died of consumption, but otherwise the family history was unimportant. On vaginal examination the condition of the vaginal portion of the cervix seemed identical with what is found in many cases of cancer. The vaginal portion appeared to be the seat of "a growth," which was friable, and bled readily on examination. The uterus was freely movable. Believing that the case was one of cancer of the cervix amenable for radical operation, the author performed vaginal hysterectomy on January 30th, 1896. The patient made a good recovery. The author had seen her several times since, and had a letter from her on November 20th, 1901, in which she said that she "enjoys fairly good health, and has had no return of the bleeding." While she was in the hospital there was no evidence of any disease in other organs. When portions of the supposed malignant growth were sent to the Clinical Research Association for examination, the report came back that there was no evidence of cancer, but that the structure was tuberculous. The author referred briefly to the writings of Pozzi, Cullen, and Whitridge Williams, from which it appeared that primary tuberculosis of the cervix was an exceedingly rare condition.

Dr. HANDFIELD JONES said that he had seen a case somewhat resembling that of Dr. Lewers. The patient suffered chiefly from hemorrhage and discharge. She had previously had recurring attacks of tuberculous arthritis in her fingers, which had led to amputations by various surgeons, so that on one hand she had only a finger and a thumb and on the other hand three fingers left. On vaginal examination there was an excavation of the cervix extending down to the vagina; tubercle bacilli were said to be present in the discharge. The patient declined a radical operation, and he therefore scraped the surface of the ulcer thoroughly, under an anæsthetic, and cauterised it with Paquelin's cautery. The patient had remained well as far as her pelvic symptoms were concerned, and her doctor had told him that no trace of the growth could be felt; but she had developed pulmonary phthisis. He asked Dr. Lewers whether in the light of this case he would consider scraping sufficiently effective.

Mr. TARGETT remarked that tuberculosis was very rare in the uterus, but much more common in the tubes; in fact, 10 or 15 per cent. of cases of tubal disease were tuberculous. He suggested, therefore, that in most cases of uterine tuberculosis the disease had developed there by extension from the tubes. This view was supported by the fact that in nearly all cases in which the uterus was affected the growth was found also in the tubes, and in a stage older than the uterine growth. Moreover, in the uterus itself the body was more often affected than the cervix. It seemed to him that this explanation was much more probable than the one which supposed that uterine tuberculosis was communicated by coitus; indeed, the latter was one of the most ridiculous theories he had ever come across, for it presupposed either that tubercle bacilli were found in the spermatozoa, or that the transmission arose from tuberculosis of the penis, which was itself a very rare condition. As regards the question of surgical intervention, it was important to remember that tuberculosis of the uterus was nearly always associated with perimetritis, leading to firm and extensive adhesions; this made the removal of the uterus a very difficult procedure. But he was doubtful if any operation such as curetting would do any good.

The PRESIDENT observed that the diagnosis of tuberculosis was often a very difficult matter without the assistance of a microscopic examination, and even the microscopic appearances were not always decisive. There was, however, a difference between tuberculosis and cancer, which was exemplified in both the cases of uterine tubercle that had come under his notice, namely,

that the growth affected the whole of the interior of the uterus, body and cervix alike; this was hardly ever seen in cases of cancer.

Mr. E. O. CROFT, commenting on the diagnosis of tuberculosis, pointed out that in Dr. Lewers' case the clinical symptoms were much more suggestive of cancer. In a case that he had lately seen the patient, who was a young married woman, thought that she was pregnant because she had had amenorrhœa for several months. There was hemorrhage, however, on making a vaginal examination. He noticed that the growth did not feel gritty and friable like cancer, but was soft and velvety; at first he was greatly puzzled by the case. But between the time of seeing her and her admission for operation he came across an account of tuberculosis in the *Journal of Obstetrics and Gynecology of the British Empire*, which led him to look into the matter, and the case then became clear. The diagnosis was confirmed by the report of the Clinical Research Association on the microscopic appearances of the growth.

Dr. MUNRO KERR (Glasgow) suggested that the growth in Dr. Lewers' case might be secondary to pulmonary tuberculosis.

Dr. LEWERS replied.

SPECIMENS.

OVARIAN CYST CONTAINING SOLID NECROTIC MASSES.

Dr. J. S. FAIRBAIRN showed a unilocular ovarian cyst containing large solid masses which had undergone necrosis although the cyst was sessile, and there was no evidence of any twisting of its pedicle. The solid mass involved about a quarter of the cyst wall, and measured 5 by 4 by 1½ inches; from it there projected into the interior several large bosses, some of which were of a deep purple colour. On section these masses were solid, though some cystic change had taken place in some of them, and they were for the most part full of blood, and necrotic. The fluid which could be squeezed from them was watery and not mucoid. Microscopically the growth was adenomatous, with a distinctly papilliferous structure. The necrosis was so advanced that the greater portion of it did not take up any nuclear stain. The tissues were engorged with blood, and contained large spaces filled with blood cells. In the parts round the necrotic portion the epithelium had proliferated and collected in rounded masses in the centre of the glandular spaces. The cyst was removed by Dr. Fenton from a widow, æt. 65, in the Chelsea Hospital for Women. It had raised up the broad ligament from beneath which it was enucleated, and though no pedicle was found, some adhesions in the lower part of the pelvis required ligature. Ten pints of dark fluid were aspirated from it before removal. There was some calcification about its base. The patient made a good recovery, and is now quite well eighteen months after operation. The cause of the necrosis may possibly have been due to the calcification at its base interfering with the blood supply.

Dr. MUNRO KERR showed (1) A uterus removed for a malignant growth of the body, which appeared to be sarcomatous degeneration of a uterine myoma; (2) A fibroma in the anterior wall of the uterus.

Dr. AMAND BOUTH showed a gravid tube with a double rupture.

Dr. F. J. McCANN showed a tubal mole removed by posterior colpotomy, with an ovarian cyst of the same side. A hydrosalpinx of the opposite side was removed at the same time. The stump of the latter was secured by ligature; but for the gravid tube he used a large Spencer Wells forceps, which was left on for twenty-four hours. He considered that a ligature in such a case involved risk of hemorrhage, from slipping or loosening of the knot; but the forceps made the procedure absolutely safe.

Dr. CULLINGWORTH doubted the accuracy of the statement that the forceps was "absolutely safe," especially when applied for only twenty-four hours.

Dr. ANDREWS and Dr. LEWERS quoted cases in which the application of forceps had been followed by hemorrhage on their removal.

The PRESIDENT said that he much preferred the abdominal route for cases of this kind.

Dr. McCANN also showed a specimen of carcinoma of the cervix where there was extensive infiltration without ulceration.

Dr. ANDREWS showed a case of congenital prolapse of the uterus in a new-born infant.

Dr. WILLIAMSON showed an umbilical cord with an unusual arrangement of blood vessels, viz., four arteries and one vein.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD AT THE ROYAL COLLEGE OF SURGEONS ON FRIDAY, MARCH 21st, 1902.

PROFESSOR BENNETT in the Chair.

GENITO-URINARY TUBERCULOSIS.

Dr. T. PERCY KIRKPATRICK exhibited a specimen of genito-urinary tuberculosis in a male patient, *æt.* 44, descriptive notes of which appeared in our last impression, page 350. In the discussion that followed,

Mr. H. G. CROLY's opinion was that X-rays are useful in detecting renal calculi, but they do not assist in the recognition of tubercle. He prefers the lumbar incision in all cases, it gives enough room to remove the largest kidney, and allows of a manual examination of the gland, and the free drainage of any pus that may be present. Of the many kidney operations he has been called on to perform, he never had occasion to adopt the abdominal route.

Dr. L. SYMES would like to know if there was tuberculous deposit in any organs other than in those named.

Professor BENNETT thought we had still a good deal to learn about the X-rays. Of his own knowledge, they failed to detect fracture of the clavicle, ribs, sternum, and pelvis. But this was from no fault in the X-ray—the fault was in themselves; it was due to their want of knowledge.

Dr. KIRKPATRICK, in reply, said the X-rays were used to examine for renal calculi, and showed no stone. In this they were confirmed by the autopsy. A careful examination of the organs other than those named revealed no tuberculous deposit.

Dr. J. B. COLEMAN exhibited a tumour of the spinal cord, which he had diagnosed and located during life. It grew from the inner spinal membranes at the level of the eleventh and twelfth dorsal segments of the cord on its right dorso-lateral aspect. It was about the size and shape of a sweet almond. A microscopic section showed it to be a myxo-sarcoma. He also exhibited a horseshoe-shaped kidney, the bond of union being at the lower end of the organs.

CASE OF FRACTURE OF BOTH BONES OF THE FOREARM.

Mr. H. G. CROLY having taken the chair,

Professor BENNETT exhibited a unique specimen of a fracture of both bones of the forearm immediately above the epiphyses, a report of which will be found under the heading of "Clinical Records," page 377.

In discussing the case,

Dr. KNOTT thought that in the return of the deformity and the separation of the fragments, the case had some resemblance to that recorded by Anson during the severe outbreak of scurvy in his command during his memorable second voyage. He could not find any cause for the non-union other than malnutrition.

Dr. KIRKPATRICK looked on the case as one of great rarity, though he thought quite different from scurvy; if due to anæmia it should be more common, nor could he ascribe it to malnutrition. In many cases, bones are soft, but such a peculiarity as the re-opening of the point of union must, he thought, be due to marked peculiarity.

Dr. L. SYMES considered scurvy as much more common to-day than we imagine, especially among the children of the wealthy. One of his last cases, that of a child in good circumstances, had hæmorrhages, swelling of the joints, limbs, and the peculiar distaste to all food other than dry bread.

Mr. H. G. CROLY said that on first looking at the cast showing the deformity in this case he felt inclined to call it an epiphyseal separation of the wrist-joint. And

again, it somewhat recalled Colles' fracture, from which however, the deep sulcus on its anterior surface differentiated it. The six weeks' time Professor Bennett allowed for healing was ample. He confessed never having met with such a case. He would just remark that it had a medico-legal aspect. If a case is set properly and osseous union has taken place, and from some cause or other the fractured extremities are again made free, the surgeon who set the fracture might find himself called on to defend an action for malpractice.

Professor BENNETT, speaking on the frequency of scurvy, said that he might just remind them that in 1669 Sir Charles Hawkins stated that he lost 6,000 sailors from scurvy during his twenty years at sea. That anæmia was not the cause of the separation of the fragments is beyond question, for it occurred when the patient was not suffering from anæmia, during her stay in a school where the feeding was good. He put forward no theory, but sought information on this obscure and unique case.

COLLES' FRACTURE.

Professor BENNETT having taken the chair,

Dr. KNOTT exhibited a specimen of Colles' fracture, in which the displacement was to the opposite side to that which usually takes place. Commencing with the early monograph of Pouteau, he traced the different theories that had been put forward up to the present.

Professor BENNETT said it was an interesting fact that Mr. R. W. Smith, from the study of specimens of Colles' fracture, completely changed his views, consequently his published views were the exact opposite of those he held at the time of his death.

Mr. CROLY said they were all much indebted to Dr. KNOTT for the elaborate paper he had just read, though when referring to the work done in Dublin on the subject he would have liked some mention of Mr. E. Adams's work on the subject.

The meeting then terminated.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT SHEFFIELD, MARCH 21st, 1902.

S. BUCKLEY, M.D., Lond., F.R.C.S., &c., President, in the Chair.

FIBROMA OF THE OVARY.—Dr. J. W. MARTIN (Sheffield) showed a specimen of a true fibroma of the left ovary removed by abdominal section from a married woman, *æt.* 34, the mother of three children, the last born seven months before operation. The symptoms had been pain in the left ovarian region, dysmenorrhœa and dysuria. There was no ascites, and the right ovary was healthy and not therefore removed. The tumour was hard and nodulated and microscopical sections showed nothing but fine fibrous tissue.

Dr. MARTIN also showed a large cystic fibromyoma of the uterus from a patient, *æt.* 24, nullipara. The growth was the size of a full term pregnancy and being partly cystic, caused much difficulty in diagnosis. The periods had always been scanty, and for the previous few months had been almost absent. The uterine cavity was not enlarged, and ovarian tumour was suspected. On opening the abdomen numerous adhesions required separating, and the growth was then found to spring directly from the whole breadth of the fundus uteri. The tumour was amputated by flaps before and behind, the vessels tied, and the stump sutured. The uterus proper and the ovaries and tubes were left behind. The patient made a good recovery. The structure was that of a fibromyoma. The occurrence of a growth of this nature at such an age is rare.

The specimens were discussed by Dr. Lloyd Roberts, Dr. Nathan Raw, the President (Dr. Buckley), and Dr. W. Walter. Dr. MARTIN replied.

MULTIPLE SUBMUCOUS FIBROMYOMATA.

Dr. E. O. CROFT (Leeds) showed a uterus about the size of a cocoon which he had removed by supra-vaginal hysterectomy from a single woman, *æt.* 39, by

reason of a gradually increasing menorrhagia and the resulting anæmia. The outline of the uterus was fairly symmetrical, but its cavity was found on examination to be very irregular. The specimen showed the unusual condition of a large number of fibromyomata of sizes varying from that of a hen's egg downwards, and all of them being practically of the submucous variety. One growth was becoming polypoid, but the os uteri was closed below it. The patient made a good recovery.

Dr. WALTER remarked that it would have been impossible to have completely removed the growth apart from the uterus even by incision of the uterine wall, and that the operation performed undoubtedly gave the patient the best chance of recovery.

Dr. CROFT also showed a large fibromyoma blocking the pelvis. The whole mass equalled the size of an eight months' pregnant uterus. The abdominal portion consisted of a spherical subserous growth, about nine inches in diameter, arising from the upper and anterior uterine wall. The pelvic portion grew from the posterior uterine wall downwards into the pelvis, which it practically filled. The uterine cavity lay more or less horizontally at the level of the pelvic brim, and was not much enlarged. The general mass presented a groove corresponding to the brim of the pelvis, and a depression posteriorly, corresponding to the sacral promontory. As the lower growth was subserous it was found possible to raise it from the pelvis, and the whole tumour was amputated just above the cervix. The stump was sutured, and the peritoneum stitched across the pelvis. The patient has completely recovered. Pressure symptoms have been only slight, but owing to the conditions present a very slight increase in the size of the growth from any cause would have caused immediate and serious impaction.

Remarks were made by Dr. Lloyd Roberts and Dr. W. Walter, and Dr. CROFT replied.

ADENO-CARCINOMA OF THE BODY OF THE UTERUS.

Dr. WALTER (Manchester) showed a uterus removed from a patient, æt. 59. The menopause was passed fourteen years previously, and during the last two years there had been severe hemorrhages. The cervix was short and patulous, but the uterus was considerably enlarged and a fungating mass could be felt growing from the fundus and body. The uterus was removed by vaginal hysterectomy. Histological examination proved the growth to be an adeno-carcinoma and a microscopic section was shown.

SARCOMA OF THE CERVIX UTERI.

Dr. WALTER also showed sections of a polypus removed from the cervix of a multipara, æt. 37. The microscopic appearance was that of a round and spindle-celled sarcoma. He therefore advised the patient to submit to hysterectomy, which was done a few days later. When the uterus was examined a small nodulated mass was found involving the mucosa and muscular wall just above the inner os. It had a slightly uneven surface, and was of a greyish pink colour. The microscopic appearance of the nodule was similar to that of the polypus.

Dr. NATHAN RAW (Liverpool) read a paper on

CÆSAREAN SECTION

twice, and embryotomy once in the same patient, with remarks on the question of sterilisation under such circumstances. The patient was unmarried.

A discussion followed in which Dr. Lloyd Roberts, Dr. W. Walter, Dr. J. W. Martin, Dr. J. H. Keeling, and the President (Dr. S. Buckley) took part, and Dr. NATHAN RAW replied.

Conviction of an Army Surgeon.

THOMAS WILSON, *alias* William Hill, described as a surgeon, late of the Army Medical Service, was sentenced to a term of imprisonment at Worcester last week for obtaining money by false pretences.

Death rather than Vaccination.

A LAD, 20 years of age, employed by a firm of printers in London, committed suicide last week rather than submit to vaccination as required by his employers, this being his way of declaring himself a conscientious objector.

Special Article.

"WHITE SCOUR" AND "LUNG DISEASE."

THROUGH the courtesy of the Right Hon. Horace Plunkett we have received one of the bulletins issued by the Department of Agriculture and Technical Instruction for Ireland. It contains reports by Professor Nocard and Principal Mettam on an investigation which they undertook at the request of the Department into the excessive mortality among calves in Munster. The causes of this high annual death-rate are known locally as "white scour" and "lung disease," and the object of the investigation was to determine what the precise nature of these diseases was, and to devise some rational method for their prevention. Professor Nocard devoted his attention to the bacteriological aspects of the diseases while Principal Mettam conducted a careful inquiry into the pathological histology of the lesions.

White scour generally attacks the calves within a few days after birth. It is characterised by violent diarrhoea and the white dejecta consist of faeces mixed with frothy mucus which is not uncommonly streaked with blood. In the severer forms of white scour death almost invariably takes place, but the milder cases often recover to succumb some weeks later to arthritis or to a caseating broncho-pneumonia, which is the pathological manifestation of "lung disease." The post-mortem appearances vary with the duration of the illness. In the most virulent cases the lesions are those of an acute septicæmia. In the acute cases of white scour there is in the umbilical vessels a soft puriform thrombus, and the mucous membrane of the intestinal tract is engorged, swollen and often ulcerated. The mesenteric glands are greatly enlarged, and the urine is albuminous. In the subacute cases there is less œdema and congestion of the gastro-intestinal tract and of the mesenteric glands, but pulmonary lesions are generally present, and there is occasionally an inflammatory effusion in one or more of the joints. If the animal survives the attack of white scour, but dies six or eight weeks subsequently from lung disease the autopsy discloses an advanced degree of caseating and suppurating pneumonia. The frequent sequence of lung disease to white scour suggested an *a priori* probability that there was an intimate connection between these two diseases.

Professor Nocard's attempts to unravel the mysteries of white scour and lung disease were at first disappointing. By culture methods it was easy to determine that the umbilical blood clot, the heart blood, and the pulp of the abdominal organs were rich in micro-organisms. *Bacillus coli communis*, para-colon, and para-typhoid bacilli, staphylococci, &c., were identified. None of these seemed to stand in a causative relation to the diseases, and inoculations were negative. After a week's discouraging work Professor Nocard received the stifle-joint of an animal which had died with an evident arthritis. Bacteriological examination of the exudate revealed the presence of some of the above-mentioned organisms, and also a very small bacterium, which stained with difficulty, and closely resembled the group of microbes described as *Pasteurella*. Inoculation of a guinea pig with a pure culture of this germ demonstrated that it was possessed of extreme virulence. The animal died with an acute septicæmia, and from its blood and viscera this special *Pasteurella* was easily isolated, provided the nutritive media were inoculated immediately after death. If, however, some hours elapsed before the inoculations of the media were made it was found that the microbic flora was almost as rich as in white scour, owing to the rapidity with which the intestinal and pulmonary germs invaded the neighbouring tissues, and thus rendered the recognition of the specific *Pasteurella* much more difficult. After Professor Nocard had made himself thoroughly familiar with the appearance of this *Pasteurella* he was able, notwithstanding the numerous secondary infections, to recognise its presence in seven out of nine calves which had succumbed to white scour.

To prove that this *Pasteurella* was not a mere ep infection but that it was the active agent in the production of white scour it was necessary to determine the

effect of its inoculation. For this purpose two calves were selected. One of these, No. 1, was obtained from a farm where white scour had never broken out. While calf No. 2 was believed to have recovered from an attack of that disease. No. 1 received in its jugular vein 3 c.c.s. of a pure culture, and No. 2 received 10 c.c.s. Calf No. 1 developed fever and violent diarrhoea, and died within thirty-one hours, while calf No. 2, in spite of its large dose, was quite lively and eagerly took its food. The post-mortem appearances in No. 1 were similar to those found in white scour. From the viscera the specific *Pasteurella* was obtained, and although the autopsy was made immediately after death it was found that secondary infections had already commenced. It would therefore seem that this *Pasteurella* has the power of so diminishing the natural resistance of the tissues to bacterial invasion that even before death secondary infections may take place. The recovery of calf No. 2 suggests that one attack of white scour produces a certain amount of immunity and opens up the question of the value of serum therapeutics in the prevention or the treatment of this disease. The subject is, however, chiefly of theoretical interest, as white scour generally runs such a rapid course that there is no opportunity given either for vaccination against the disease or for testing the value of serum from an immunised animal in its treatment.

Having established the etiological connection of this form of *Pasteurella* with white scour, it became necessary to determine by what route infection occurred. Professor Nocard rejects for sufficient reasons the suggestions that separated milk or improper feeding has anything to do with causing white scour. The constancy of umbilical lesions and the presence of the specific growth in the umbilical vessels suggest that this is the commonest route, and in Professor Nocard's opinion infection takes place after birth by the calf, in its attempt to stand, dragging the ruptured cord over the contaminated stable floor.

Of four of the prophylactic measures suggested by Professor Nocard we entirely approve. These may be briefly summarised as a clean bed, disinfection of the external genitalia, the early ligation of the cord, and the application of an antiseptic dressing to it. We cannot however agree with him when he suggests the desirability of *ante-partum* vaginal douching. At the commencement of labour the vagina of a healthy cow as of a healthy woman doubtless contains a large number of saprophytic germs which not only are not pathological, but may, by generating lactic acid, prove a bar to the entrance of pathological bacteria. The introduction into the vagina of a syringe by an attendant who can have no accurate knowledge of antiseptics is, in our opinion, likely to infect the vagina and to carry into it the very germ for the removal of which prophylactic irrigation is recommended. So far as we can gather from the report Professor Nocard has not found the specific *Pasteurella* in the vaginal secretion of a healthy cow, and the case he describes in support of his hypothesis that infection of the cord may take place during its passage through the vagina is explicable on grounds which seem to us, at all events, more probable.

During Professor Nocard's first visit to Ireland he devoted his attention chiefly to the study of white scour. Most of the calves are born in April, and it is not till June or July that lung disease becomes prevalent. On the occasion of his second visit he had several opportunities of investigating lung disease. In the lungs of all the cases which came under his observation he recognised the presence of an organism with which he was already familiar. He had previously identified it as the cause of ulcerative lymphangitis in the horse. Preisz had found the same germ in purulent foci in a sheep's kidney, and Sivioli had demonstrated it in patches of caseous pneumonia among Argentine sheep. This organism is a short thick polymorphous bacillus, and is easily stained by Gram's method. Its relation to lung disease is extremely interesting. A healthy calf may be forced to inhale a pure culture of it in the form of a spray, or may be subjected to intra-tracheal, venous, or pulmonary

injections of it without developing any symptoms of disease. If, however, the normal resistance of the tissues be first impaired by the intra-abdominal injection of a pure culture of *Pasteurella*, which has been raised to such a temperature that it contains only the dead bodies of the bacilli and their toxins, the animal when infected in any of the foregoing methods with the Preisz-Nocard bacillus develops a caseating and suppurating pneumonia. The Preisz-Nocard bacillus is a common saprophyte, and occurs in mud and manure scrapings. It is powerless to produce mischief in healthy calves, but rapidly acquires pathogenic properties in those whose resistance has been lowered by a previous infection of *Pasteurella*.

The summary in the prefatory note of Professor Nocard's researches is brief, but not accurate. The Professor does not state "that 'white scour' and 'lung disease' in calves, in spite of the difference in the seat and symptoms of these maladies, are one and the same disease." He says that he has been able to establish a close connection between "white scour" and "lung disease," and subsequently that both these diseases proceed from one and the same infection, of a "*Pasteurella*" nature. He immediately proceeds to explain this latter statement by pointing out that the specific *Pasteurella* may kill the subject in the course of a few hours with symptoms of acute septicæmia. If the animal survives the original infection, the resistance power of its tissue is so impaired that the way is opened for secondary infections, chiefly of intestinal origin, and symptoms of white scour appear. Finally, if it resist the intestinal infection and recover from white scour, it may yet fall a victim to the pulmonary infection, in which the most active agent is the Preisz-Nocard bacillus, and die with lung disease.

Furthermore, if we have read Professor Nocard's report correctly, paragraph 2 in the Summary is entirely wrong. The *Pasteurella* is not the microbe which produces pseudo-farcinous ulcerative lymphangitis in the horse, and adenitis and caseous broncho-pneumonia in the sheep. These lesions are caused by the Preisz Nocard bacillus, which is non-pathogenic for calves till their resistance has been impaired by *Pasteurella* infection.

In conclusion, we wish to express our admiration of the excellent work done by Professor Nocard and Principal Mettam, and we hope that the day is not far distant when our veterinary colleges will contain a department for original research in some way comparable to that at the National Veterinary School of Alfort.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, April 5th, 1902.

At the Society fur Innere Medezin, Hr. Plien communicated a note on

THE DEVELOPMENT OF A CARCINOMA ON THE BASE OF A TUBERCULOUS ULCER.

In a woman in the Gitchinin Hospital suffering from pulmonary phthisis tubercle bacilli were found in the fæces, and tuberculous ulcers of the intestines were therefore assumed to be present. The patient died fourteen days after admission, and the autopsy revealed numerous tuberculous ulcers in the colon, and at the site of one of these a carcinoma had developed.

Hr. v. Leyden observed that carcinoma frequently formed on the site of tuberculous affections, but such a growth developing on a tuberculous ulcer of the intestines had never been reported before.

Hr. Kuhn said that Zenku had reported three cases in which carcinoma had developed on the site of tuberculous ulcers of the œsophagus.

Hr. Litten then gave an address on

ENDOCARDITIS.

He had been led to write a paper on the subject by one

read in Wiesbaden by Lenhartz two years before. These two years he had made use of in verifying the correctness of the views then expressed. This subject, and the allied one of acute rheumatism, were at present in a state of ferment, as the view had been expressed that both diseases were due to a pyæmic process dependent on pus cocci. If this view were correct, the subject of endocarditis would be more simple than the speaker held it to be. Up to now two forms had always been distinguished—the granulation and the ulcerous. This distinction was insufficient, as it was an anatomical one only, and the differences between them were only gradual, and the etiological and clinical conditions were ignored. In 1881 he had proposed that these names should be dropped, and instead of them to use the term rheumatic and septic, dividing the latter cases into a rheumatoid and septic group, into the first of which all cases of malignant endocarditis would fall which were caused by articular or other rheumatic affections where the latter group would include septico-pyæmia. Since that time he had arrived at another terminology, viz.: benign and malignant endocarditis, according to the danger to the life of the patient, the latter group being again divided into a purulent and non-purulent group. The best known form, endocarditis benigna, especially associated with articular rheumatism and leading to valvular mischief, was benign as regarded the life of the patient. The affected valvular tissue had no further tendency to morbid change. The sclerosis led to a harmless roughening with thickening and shortening of the valves. The changes were met with exclusively in the left heart. The thrombi forms of fibrin, leucocytes and bacteria crumbled off and were carried by the blood stream, forming thrombi in the vessels, these being always confined to the arterial circulation, the brain, extremities, kidneys and spleen. They acted only mechanically. If infarcts were found in the lungs they came never from the left but from the right heart or from the veins. The endocarditis was not necessarily immediately associated with the basic disease; indeed, a considerable time, even years, might intervene between the two. Not a few cases ran their course without symptoms, whilst as a rule there were fever, pain in the cardiac region, palpitation, and dyspnoea. Complete recovery was possible; as a rule, however, the disease was chronic, and it led to contraction of the valves. Frequently there was myocarditis.

As regarded etiology the chief cause was rheumatic affection. For five or six years he had made methodical investigation into the percentage of the different causes of the disease. Out of about 30,000 patients 4 to 500 had heart mischief, which in from 30 to 35 per cent. was due to acute articular rheumatism, about 30 per cent. to other rheumatic affections, whilst in the remaining 35 per cent. no cause could be ascertained. This agreed with statistics published from the Moscow hospital.

He had met with the purulent form in grave puerperal fever; in the uterine veins thrombi with purulent material leading to multiple purulent joint inflammation, pericarditis, hæmorrhagic nephritis, metastatic ophthalmia, pemphigus, extensive cutaneous phlegmons and death. At the autopsy he found the vein that led from the diseased site filled with pus and decomposing material with purulent metatasis in all the organs, in the joints, lungs, intestines, &c., and in both right and left

heart, a slight deposit of granular excrecences, or destruction of the valves, as for example the semilunar valves separated, the mitral destroyed, or the papillary muscles separated and the tendons torn. In spite of all this the heart was not the *punctum saliens*; it did not determine the prognosis. He had notes of thirty-five cases, the course of which was uniform, whether endocarditis was present or not. The clinical course was distinguished by the violent onset, the high temperature without remissions, the erratic rigors, the quick course of eight to fourteen days, and the bad prognosis. Exceptionally a month's course was observed. All the cases had a fatal termination. Eighty per cent. of the cases related to women in puerperia; ten of them had purulent panophthalmitis, but the complication was not on the whole very frequent.

Endocarditis maligna non purulenta was caused by the same basic diseases as benign endocarditis. The characteristic was the absence of the pyæmic character. If there was clotting in the veins it was benign, effusion into joints was not purulent, but serous or cloudy serous. But the disease was not by any means harmless, although not as malignant as the preceding group. The larger percentage of the cases died, but recovery might take place. The disease lasted longer, one of nine months even had been observed. The disease of the heart did not play such a subordinate role, but was prominent and showed itself as the chief clinical feature. At autopsies sometimes only slight deposits were found on the valves, sometimes destruction of them.

Bacteriology had shown that every endocarditis, with the exception of the atheromatous kind, was of bacterial origin, and that it was a complication of some basic disease. As regarded the benign form the exciting cause varied. Up to the present, in spite of recent observations, no constant factor had been discovered. The cause of the malignant form had been found. In eighteen cases of the non-purulent form he had obtained a positive result six times, among them two rheumatic cases in which a streptococcus gracilis was found. In the other cases staphylococci, streptococci, and pneumococci were found, but not in the non-purulent form. The biological properties of the organisms varied, however, so that it was not possible in a pure cultivation to say whether they came from a purulent or non-purulent form. The gonococci was peculiar in this connection. This was known as the cause of gonorrhœal endocarditis, so that there could be no doubt about it. A large number of grave cases of gonorrhœal endocarditis were known, but there were no pure collections. The gonococci had not set up a purulent inflammation. For the rest it must be confessed that the bacteriological knowledge of to-day did not suffice to mark off the boundaries of the purulent and non-purulent malignant forms of the disease.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, April 5th, 1902.

THE EFFECTS OF ELECTRIC DISCHARGE ON THE NERVE CENTRES.

At the "Gesellschaft der Aerzte" Jellinek recorded a number of experiments he had performed on dogs, frogs, mice, &c., with the electric current; both continuous and intermittent, with different quantities and intensi-

ties. The turtle and frog could not be killed with high tensions of electricity, but mice were easily killed with twenty or thirty volts of a continuous current. He next related the effects on man and gave the example of a finisher in Vienna, who received 1,000 volts and lingered for the space of fourteen days after. The post-mortem revealed degeneration of the centres. He demonstrated similar conditions in dogs and guinea pigs by means of the microscope after hardening and staining portions of the ganglia. This degeneration was prominent in the posterior part of the spinal cord as well as the periphery nerves. There was also hæmorrhage in the white and grey substance of the nerve substance as well as the motor ganglion themselves.

Benedict protested against any suggestions for executing murderers by means of electricity. Why, he asked, should it be a duty of the medical profession to discover an easy method of getting rascals into eternity who ought never to have been born, while many others for small offences have had to suffer punishment for long periods which we never think of diminishing for the sake of the offender.

Pauli said the difference in the continuous and intermittent currents was that the one was electrolytic, while the other was thermal and mechanical in its operation. The constant went deeper owing to the great quantity of electricity directly from the cataphore, and may therefore be termed cataphoric and electrolytic, while the intermittent represents a thermic and mechanical condition.

Richter agreed with Jellinek's observation of hæmorrhage in the spine, as he had also had cases where this symmetrical or ecchymosed on both sides of the spinal cord, although it is affirmed that no such observation has yet been made by the forensic department of the Vienna University.

The use of electricity as a means of execution had no humanitarian purpose to serve, nor could he see any special advantage over hanging, as the closure of the carotid by the latter method produced unconsciousness as easily and speedily as electricity, in most cases with more accuracy.

Sternberg doubted the accuracy of hæmorrhage into the ganglionic cell as this component part of the organism had no blood vessels, its nutrition being supplied by absorption.

Topolanski remarked that great caution must be observed in deciding hæmorrhage as a constant symptom among the injuries due to electric discharges. In the case of injuries to the eyes from lightning too much care cannot be exercised.

Beck thought the immunity of the turtle was due to the hard covering of the animal, as it may conduct it off rapidly.

Freund said the results of Jellinek accorded with his own, which he had recorded before the Society on a former occasion under the title of Electricity under Chloroform. The narcotised animals were acted on by a Ruhmkorff induction coil for the intermitting current. This produced paralysis of the animal, dogs particularly, varying in time of recovery to the intensity of the shock. The degenerative changes in the nerve system as well as the inflammation and hæmorrhage of the skin at the point of application are in perfect accord with those of Jellinek.

DERMATOLOGY.

We learn with satisfaction that Docent Dr. K. Kreibich has been entrusted with the University instruction in dermatology in the room of the late Prof. Kaposi, who was Hebra's successor in this office. It may also be added that Kreibich was Kaposi's assistant for many years, and is entirely familiar with the duties of the office.

DEATH OF PROFESSOR ALOF PARISH.

Another of Austria's illustrious dermatologists has passed away in the person of Professor Jarish, of Graz. He was born in Vienna, 1850, studied here and qualified in 1873, and was shortly after this appointed assistant to Professor Hebra, the Austrian authority on skin disease at that time. In 1888 he was appointed professor of dermatology at Innsbruck, where he remained till his appointment to the same office at Graz in 1892, where he died on March 26th. He was an extensive writer, and has left a large amount of valuable research for the benefit of his successors. The pigment of the skin absorbed his special attention, on which he has written several monographs. His latest appeared in 1900 on skin diseases in general.

Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, April 5th, 1902.

At the recent meeting of the Royal Society of Physicians of Budapest Dr. Egmont Baumgarten exhibited a case of an affection of the accessory sinus of the nose associated with

PARALYSIS OF OCULAR MUSCLES.

He pointed out that chronic diseases of the sphenoidal sinus are usually accompanied by severe symptoms, and on account of its close neighbourhood to the eye it might entail various diseases of that organ. In the patient shown a year ago he complained of much headache. Soon after he became unable to open the eyelid. Two months ago diplopia developed. Diseases of the antrum of Highmore and of the frontal and ethmoidal sinuses having been excluded, the headache and other severe symptoms led him to seek for the seat of the disease in the sphenoidal sinus, and he therefore made an opening into the sinus through its anterior lower wall.

The ptosis and the protrusion disappeared on the following day, and the patient could move his eye better. Two days later, after the removal of the anterior part of the middle turbinal, he scraped out the granulations lodged in the sphenoidal sinus. The patient felt very faint under this treatment, otherwise he felt himself quite well. The eye now moves inwards to the middle line, upwards only a little, downwards tolerably well. The posterior wall of the eye was intact. The patient denied having had syphilis, nor had he previously had any infective disease. This made it very difficult to assign the real cause of the affection. That the eye-muscle paralysis is dependent upon the sphenoidal disease appears likely, and this view is confirmed by anatomical considerations; it is confirmed, moreover, by the result obtained.

Dr. Gross Gyula exhibited an unusual case of

BARLOW'S DISEASE,

which had not previously been observed in Hungary, at least it is not mentioned in medical literature.

The child, aged 15 months, was fed from birth to the age of 12 months simply on boiled milk, and later on she was given a mixed diet (soup, eggs, and meat). On this régime the child, it is stated, developed very well. Her first tooth came in her tenth month, and she began to walk in her twelfth month. About six weeks previously her limbs began to be the seat of pain and to become swollen. On the two following days she had bleeding from her mouth and bloody stools. At the end of January her head suddenly became swollen, as did also the eyelids. It was in this condition that she was brought to the surgical section of the hospital, where the case was kept under observation until February 12th. The diagnosis was *hematoma capitis*. The swelling diminished visibly after the application of wet compresses, so that at the time of her discharge from the hospital no tumour could be felt. On February 25th the child was again brought to the hospital. She looked delicate, and was very under-developed, and showed the characteristic signs of rickets. The shafts of the left thigh bone and the left tibia were enlarged, and on palpation hard, irregular swellings could be felt. Both parietal regions of the skull were covered with a swelling, through which, on deep pressure, one could feel the sparsely-covered bone. Both upper and lower eyelids as a whole were of a bluish-red colour. From these symptoms the diagnosis was established, viz., Barlow's disease. Especially characteristic were the following symptoms: Rapid development, pains in limbs, subperiosteal hæmorrhages over the long bones and the skull bones, in addition to hæmorrhages from the mouth and bowel. Barlow's disease would appear to be an affection—*sui generis*—the etiology of which is still obscure.

Afterwards Dr. Klug Nandor read a paper on

TUBERCULOSIS AND THE ORGAN OF HEARING.

Tuberculosis of the hearing organs usually occurs as middle-ear suppuration. The process is mostly secondary, or it accompanies bone and lung tuberculosis, especially in children. Tuberculous ear discharges form 0·7 per cent. of all ear diseases. The path of infection may be either from the mouth through the Eustachian tube, or through an already present perforation of the tympanum from the external auditory meatus, and, finally, *via* the blood. The demonstration of the presence of the tubercle bacillus is often difficult, in some cases it is indeed impossible. The clinical picture is variable. A most characteristic sign is the absence of a reaction and pain. The discharge is copious, thin and foul-smelling. The process extends to the petrous bone, to the labyrinth, and ultimately carries of the petrous bone and impairment of the hearing result. It leads to facial paralysis, and to erosion of the blood vessels. Severe complications such as meningitis, thrombophlebitis, cerebral and cerebellar abscesses may follow tuberculous affections. Milder cases are met with, especially in children. The prognosis is always unfavourable. Even when it heals, defects of the tympanum and impairment of hearing remain behind. The deeper the carries of the petrous bone extends, the graver is the prognosis, nevertheless by operation some relief can be afforded. The treatment must be local and general. For such patients good air and good nourishment are advisable in addition to the local treatment. By conservative measures we must

provide for the free drainage of the pus so that retention may not occur, and apply antiseptics. The best result, however, is to be obtained by operative measures, when we transform all the middle ear cavities into one cavity, and remove all carious bone. The operation is indicated in every case of middle-ear tuberculosis, in which the lung tuberculosis has not yet made much progress.

The Operating Theatres.

CENTRAL LONDON THROAT AND EAR HOSPITAL.

THYROTOMY.—Dr. PERCY JAKINS operated on a man, æt. 25, who had been admitted for loss of voice and a sense of suffocation, arising from a papillomatous growth below the right vocal cord; the tumour was plainly seen on laryngoscopic examination. Both cords were freely movable. The patient had already submitted to three attempts at removal *per vias naturales* whilst in the country, but these had not been successful. On admission, which was a month after his first having attended as an out-patient, the aphasia was worse, the sense of suffocation had increased, and the patient could not lie down comfortably. Laryngoscopic examination revealed slight fixation of the right vocal cord, and inflammatory mischief caused the growth. There was no history of syphilis or of tubercle. It was decided to remove the growth by splitting open the thyroid cartilage, and this was done as follows:—The patient was anaesthetised with chloroform, the head was thrown well back, and an incision about four inches in length made in the median line from the hyoid bone to two inches below the cricoid. The superficial fascia and the sterno-thyroids were next divided, also the deep cervical fascia; the trachea was now exposed and a sharp hook was inserted into the second tracheal ring, the isthmus of the thyroid being drawn down by retractors. The third, second and first tracheal rings were then divided, and a Hahn's tampon cannula which had been previously dipped in a solution of perchloride of mercury (1 in 1,000) was inserted. The anaesthetist now administered the chloroform through a tube which fitted into the Hahn's cannula. Twenty minutes were allowed to elapse in order to allow the compressed sponge around the tube to expand and so prevent any blood running down into the lungs. The thyroid cartilage was then exactly divided in the median line, and the two also held apart by retractors; the internal surface was brushed out with adrenaline (1 in 1,000) in order to arrest the capillary oozing. The growth was easily seen, and was found to extend from below the right vocal cord to the lower part of the cricoid; it was removed with scissors curved on the flat and forceps. The internal surface of the larynx was swabbed out with a solution of chloride of zinc (30 gr. to 3j); two wire sutures were placed through the thyroid cartilage, the Hahn's tube removed and the external wound sewn up, a piece of double cyanide gauze being placed in the lower part for drainage. Dr. Jakins said that he quite understood the three failures to remove this growth *per vias naturales*, as it extended such a distance downwards; the instrument or instruments used could only pull away a small portion of the upper part of the tumour, which was no good to the patient, for these procedures only caused it to become

more inflamed, and might have set up in a simple growth a malignant action, for this reason he had considered it advisable to perform thyrotomy, as thereby he could see the growth and how far it had extended, and remove it easily if its size rendered this possible, and, on the other hand, if the disease were found to be very extensive, he could at once perform excision of the larynx. The patient made an uninterrupted recovery, and left the hospital at the end of ten days feeling much better, his voice was rapidly returning, and the sense of suffocation on lying down completely gone.

The growth was examined by the pathologist to the hospital (Dr. Wyatt Wingrave) and found to be a simple papilloma with active cell proliferation, showing, as pointed out by Dr. Jakins at the operation, that if many more attempts at extraction *per vias naturales* had been made the tumour would undoubtedly have become malignant.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d., Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 9, 1902.

HOSPITALS AND PAYING PATIENTS.

SOME recent correspondence in *The Times* brings forward once again the vexed question of paying wards in general hospitals. The system is advocated on the one hand as a means of preventing hospital abuse by affording those who are able to pay something short of the usual fees the advantages of hospital treatment, while it is combated on the other hand on the ground that it is merely another device for depriving practitioners of an opportunity of gaining a livelihood, an argument which, though in the main true, is not likely to weigh with the lay governors of our medical charities unless more cogent reasons can be advanced for restricting further moves in this direction. Sir Henry Burdett stands forth as the advocate of the present system of pay-wards, which he would apparently like to see generalised, although, in deference to the feelings of the profession and to the class prejudices of the patients, he is prepared to advocate a stricter line of

demarcation between paying and non-paying patients, at any rate in respect of the buildings assigned to the two classes of patients. This is mere trifling, for it does nothing to attenuate the injustice done to medical practitioners by the allocation of funds belonging to charitable institutions to the treatment though not to the maintenance, of a totally different class of persons. What is a paying ward after all? It is merely a portion of the hospital buildings set apart for the reception of patients who are able and willing to defray all or part of the cost of maintenance. As for the medical attendance this is furnished gratuitously by the medical staff of the particular hospital so that even if we allow that a payment of two or three guineas a week covers the cost of nursing and maintenance, which, judging from the scale of charges in nursing homes cannot be the case, these patients, all the same receive the best possible medical attendance for nothing. The so-called safeguards suggested by Sir Henry Burdett are absolutely illusory, and do not justify this description. This fact is evidently realised by the Honble. Sydney Holland, who, while he admits the necessity of providing for the needs of patients who are not in a position to cover the heavy expenses incidental to a prolonged illness, nursing, &c., proclaims the undesirability of making such provision in connection with the general hospitals. What is wanted, he urges, is a building specially adapted for the purpose, separate, and distinct from any hospital properly so called, in fact, a sort of cheap nursing home, in which the payments would comprise medical or surgical attendance by a resident medical officer, leaving the patients to make their own arrangements with their ordinary medical advisers. It must be admitted that the cost of a first-class nursing home, *plus* fees for medical attendance, are prohibitive to many persons who would however be only too glad to compound on terms within their reach. We quite believe that such an institution would pay its way and even give a fair return on its capital cost, and it would obviate in great part the objections felt and expressed by practitioners to any extension of the pauperising influence of our large general hospitals as at present administered. Perhaps Mr. Holland, who is indefatigable, would be willing to elaborate such a scheme in order that it may be duly considered in its double aspect, from the point of view of the hypothetical inmate as well as from that of the medical practitioner. The main point to be borne in mind is that medical attendance is a thing worth paying for just as much as maintenance, which is only another way of affirming the principle that the medical labourer is as worthy of his hire as labourers in other departments.

AN ANTI-VACCINATIONIST HOSPITAL.

THE Hospital of St. Francis, New Kent Road, London, was established in the year 1898, and has a country branch at Loughton, in Essex. In the advertisement pages of *The Medical Directory* it is

announced that "by the foundation of the hospital vivisection may never be practised in it, nor will flesh foods be used excepting under special circumstances." The position of this charity as opposed to vivisection and as supporting vegetarianism is thus clearly defined, and may be accepted with equanimity, although it may be pointed out that vivisection experiments, so far as we know, are never under any conceivable circumstances practised in hospitals. There are other facts connected with the Hospital of St. Francis, which, in our opinion, deserve the careful attention of the medical profession. The fourth annual court of the governors of the institution was held on the 25th ult., with Mr. Arnold F. Hills, a well-known vegetarian, in the chair. The Chairman, in moving the adoption of the report, stated the principles upon which the work of the hospital was based. So far as vegetarianism is concerned there can be no possible objection to its adoption or rejection either by any individual or by any collection of individuals. It is a very different thing, however, when the Chairman claims that "by a natural rational diet they could overcome the diseases to which the human system was liable." That extravagant claim the Chairman backed up by saying that their statistics bore out the truth of this belief. What does that statement mean? It infers that the whole range of disease, medical and surgical, can be cured by attention to diet. If that be not the Chairman's meaning, what particular diseases does he claim to have cured at the Hospital of St. Francis by dietary? The enormous importance of diet in the treatment of stomacachic derangements, gout, and many conditions of debility and so on is undoubted, but that is a totally different matter from the assertion that diseases of all kinds, say cancer, softening of the brain and acute rheumatism can be positively and actually cured by a choice of food alone. If the belief of the hospital authorities be that arrived at by the Chairman, then the position of the medical staff must be more or less seriously compromised. But if the alleged powers of vegetarianism do not afford sufficient ground of anxiety to the medical gentlemen in question, other declarations of the Chairman at the same meeting with regard to vaccination, in our opinion, demand the attention of all who are jealous of the traditions that govern the medical profession in the United Kingdom. Speaking of vaccination the Chairman is reported to have said that St. Francis Hospital had a lesson to teach. "They regarded disease as a process of eliminating matter from the system, and they thought the best way to cleanse the system was to put it upon a wholesome diet. Vaccination was one of the fads of the medical profession, who believed it was necessary to inoculate the system with a mild form of disease in order to prevent the more serious one from being taken. He thought St. Francis Hospital would show that it was possible to cleanse the system by the natural methods of life." After such an attack upon the methods and beliefs of

orthodox medicine it is difficult to see how any self-respecting medical man can retain his connection with the institution. In any case we think the attention of the General Medical Council should be drawn to the fact that qualified medical men are attached to a medical charity of which the avowed beliefs and curative methods are of so extraordinary a character. On referring to the advertisement pages of *The Medical Directory* for 1901, we find that it is described as a general hospital, with special departments, of which one is reserved for the "Diseases of Digestion," a subdivision that even in these days of multiplied specialism has not, to our knowledge, been hitherto considered necessary. The same authority gives the name of Dr. J. Oldfield as physician, and of Dr. D. G. Halsted as assistant-physician; Mr. F. J. Willey, M.B., as surgeon and Mr. J. W. McVine, M.B., as assistant-surgeon. Mr. M. Agar is aural surgeon, Dr. F. J. Fielder, ophthalmic surgeon; and Mr. P. J. Spencer casualty medical officer. We shall await with some interest any disclaimer those gentlemen may have to make regarding the unorthodox views advanced by the Chairman in the name of the Hospital of St. Francis. Meanwhile we conceive it our duty to lay the facts before the medical profession, the members whereof cannot be too careful about the nature of the institutions with which they allow their names to be associated. We shall be prepared to hear that each of the above-mentioned members of the staff has heard with astonishment the declaration that it is the mission of the Hospital of St. Francis to supplant vaccination with a restricted diet in the fight against small-pox, and to advance vegetarianism as a "cure-all" in disease. It would be interesting to learn what drugs, if any, are used in the treatment of patients at this institution.

OSSEOUS COMPLICATIONS IN TYPHOID FEVER IN CHILDREN.

TYPHOID fever, though not uncommon in childhood, always brings with it the element of surprise. We do not look upon it as a disease of infancy, and we are consequently liable to fail to recognise it when it does occur. This is all the more likely when the disease is attended with complications and does not run the course which in the adult is normal. In the young, growth and development all modify the action of the poison, and as long recognised the marrow cells and the elements of the growing bone tissue profoundly affect the toxin. In the child the onset of typhoid is frequently sudden—headache, vomiting, and often convulsions, simulating pneumonia, particularly in the high temperature, which often reaches 104° in the first twenty-four hours and oscillates like the pyrexia of a case of blood poisoning. In a few days the little patient complains of pain in its limbs, which may be mistaken at first for sharp growing pains, or if the child has been exercising more than usual may be looked on as muscular pains. This error is all the more likely to occur from the relief that warm woollen bandaging

gives. After a little—a few days—the glands of the inguinal region swell and become painful, and pressure on the long bones both of the upper and lower extremities causes the child to complain of a deep-seated pain. If left quiet it will be noticed that the patient flexes the thighs on the belly, adducts them, rotates them inwards, and whines with pain on any passive movement of the hip-joint. All the larger joints suffer a form of peri-arthritis, and become painful; the patient cannot move them and cries out if passive movement is made. Effusion occurs in the hip, knee, ankle, wrist. A high temperature, often a copious perspiration, with its attendant sudaminous rash are present, and little, if any, enlargement of the spleen. The recognition of typhoid under such conditions is not an easy task, and a diagnosis of articular rheumatism would be likely unless great care was taken, and that the physician kept well in mind that in typhoid fever in children inflammation of the long bones and of the larger articulations not infrequently resulted in severe cases. In the less severe osseous complications, as in the more severe, the physician must be on his guard, for ankylosis in some cases and luxation in others have been known to follow. In the young these joint troubles sometimes appear at the very beginning of the disease. Bouillaud's case died on the third day after admission to hospital. There was suppurative arthritis of the tibio-tarsal articulation, and the Peyer's patches were characteristically affected. Such cases M. Marfan designated as *arthrites suppurées pyohémiques*, and he considered them as the result of a secondary infection. This view did not meet with general acceptance. M. Robin believed in a form of arthritic typhoid, and in the case of M. G. See's patient, whose complaint was of articular pains in the shoulder and knee, believed his theory found support. In Straus' case the bacillus of Eberth was found in the effused liquid of the joints. Many other cases have been reported in which the bacilli were found. The period of time that elapses from the attack of the fever to the beginning of the joint troubles seems to bear some relation to the severity of the attack. Where the interval is long the attack usually ends favourably, and if the interval is short the case usually ends fatally. When the symptoms of the joint trouble are deferred until the fever had almost run its course, the case usually terminates without any permanent injury to the patient, though the joint pains may have been severe, as in M. Bordier's case and that of M. Grancher. In the former, a child of thirteen years, the inflammation not only attacked the large joints but also the temporo maxillary articulations. Vidal considers that these articular and osseous troubles are not found in patients over twenty years of age, and he holds that in young subjects the bacillus of Erberth has a predilection for osseous tissue. We have, however, said enough to draw the attention of our readers to a complication of typhoid fever in the young which is dangerous to the life of the patient, and

even if he should survive is liable to occasion deformity and seriously lessen the movements of the limbs. Unfortunately, our British and American text-books make little mention of this interesting and dangerous complication, and the reader who seeks further information on this subject should consult French authors. We wish we could add that our French brethren had been as successful in the therapathy of the inflammation as they are in its clinical description; but we regret that so far no remedy seems to do any good, and in rest and careful dietary lie our only hope.

Notes on Current Topics.

The Prevalence of Actinomycosis.

WE are not in possession of any trustworthy data concerning the actual prevalence of actinomycosis in human beings although the subject is one of the greatest importance if only to enable us to ascertain whether or not the disease is more frequently met with than of yore. It is highly probable that in many instances the disease remains a purely local manifestation and escapes diagnosis, indeed, it is not less probable that even in more extensive invasions it still escapes recognition, owing to the fact that the diagnosis can only be made by the aid of the microscope. Dr. Poncet, of Lyons, has collected notes of twenty-one cases since 1900 in France. Of this number eighteen occurred in the cervico-facial region, a distribution which is explained on the assumption that the infection usually gains entrance into the organism *viâ* the mouth. Of the three other cases one involved the thorax, another the uterine adnexa, and the third affected the anus and rectum. The relative proportion of cervico-facial localisations observed in this series does not, however, hold good with regard to the total statistics for France. Up to the present some 146 cases of actinomycosis have been recorded, and of these only seventy-nine involved the cervico-facial region, the others being cases of visceral actinomycosis. Statistics based on the investigation of the ultimate course of 257 French and foreign cases seem to show that while the mortality does not exceed 2 or 3 per cent. in the cutaneous cases, it rises to 10 per cent. when the disease attacks the superficial structures of the cervico-facial region, and 30 per cent. when the deeper structures are attacked. When the intestine is the seat of the mischief the mortality attains a proportion of 65 per cent., 85 per cent. when the lungs are affected, and 100 per cent. when the disease involves the liver or nervous system. The gravity of the visceral cases is attributed to the pernicious influence of the secondary infections, which almost invariably complicate these forms of the disease. Curiously enough the author says nothing in reference to the effects of the medical treatment of the affection, though the greatest benefit has attended the administration of iodide of potassium in large doses. The failure of this drug to relieve in the

graver cases is no doubt due to the secondary infections just alluded to, which are not amenable to the iodic treatment.

Ideal Road Cleansing.

By slow degrees the art of cleansing the streets is approaching perfection. The principle is now fairly established that washing is needed as well as sweeping in order to approach a cleanliness of the kind provided by bountiful Nature in her rain-clouds. The sluicing of pavings necessitates the previous laying of smooth and impermeable roadways. The plan adopted in the United Kingdom has hitherto been to fix hydrants at intervals along the street mains, and by means of detachable hose to bring abundant streams of water to play upon the surfaces to be cleansed. In Berlin the local authorities have gone one better, for they have introduced a sort of compound water-cart and sweeper which sluices the paving, sweeps up the mud, and collects the refuse, all in one operation. The new contrivance is reported to work well in practice, and if so, there should be nothing in the way of its wide adoption in our own country. The important bearing of clean and well-kept roadways upon the health of towns has been recognised at its true value only during recent years. One of the most important observations of recent times in connection with this point was the probable relation of summer diarrhoea to the microbes of the horse-dung with which our streets is so freely contaminated. It is an ill wind, however, that blows nobody good, and, curiously enough, the old muddy streets brought grist to the mill of the shoeblacks in a way that has now become one of the golden myths of that unassuming craft. It is a matter of sober statistical fact that the earnings of boys belonging to the Metropolitan Shoeblacks Association have been considerably reduced under modern sanitary administration.

A Vendor of Leadless Glaze Ware.

Of all the death tolls levied among the industrial population of the United Kingdom none is more disastrous than that of lead-poisoning due to the use of lead-glazes in the making of earthen and china-ware. For a long time medicine has unravelled with patient accuracy the long list of maladies, such as anæmia, epilepsy, Bright's disease, and various palsies connected with this dangerous trade. With no less unerring precision preventive medicine has shown how the whole of the terrible group of results described generally under the name of "plumbism" may be entirely and altogether avoided. The simple expedient of leaving lead out of the glaze goes straight to the root of the matter, and saves straightway a vast mass of unnecessary human misery and loss of life. The leadless glaze is now a perfectly satisfactory trade result and the only bar to its general adoption is the opposition of the manufacturers, who find it easier or more economical to stick to their old poisonous processes. Under these circumstances it is gratifying to learn that at least one retail firm sells no article that is made with

a lead glaze. It is well to do honour to practical humanity of that kind and we have much pleasure in stating that Messrs. Franks and Co., of 59, Eastcheap, London, have been enterprising enough to stock leadless glaze ware only. The next thing is for all customers to insist that the ware they buy shall be made with the harmless glaze. In that way, as we long ago pointed out, it is in the power of the community to stretch out a saving hand to the potters.

Accidental Death in a Hospital.

AN unfortunate death through misadventure has been recently the subject of a coroner's inquiry in London. The facts are briefly as follows: a child of ten underwent a simple operation, which was performed by an assistant house-surgeon at St. George's Hospital. During the operation the child was placed upon a hot-water pillow, which was protected by a towel soaked in carbolic lotion. In some way or other, however, the pillow must have been allowed to come into contact with the body of the child, who died subsequently from the resulting burn. Our sympathies are with everyone concerned—with the operator, with the sister in charge, with the hospital authorities, and last, but not least, with the friends of the unfortunate child. There can be no doubt whatever that this unhappy event falls within the limits of preventable accidents. On the other hand, it is equally certain that in the best-regulated institutions in the world there must be a small margin of error so long as human nature is constituted as it is. Indeed, the very rarity of such unhappy occurrences points to the extreme and unceasing care which is exercised and maintained amid all the rush and hurry of busy hospital work. The only wonder is that serious mishaps are not more often heard of when the energies of the nursing and the medical staff are often overtaxed day by day and month after month. The accident itself arose from a comparatively recent and commendable practice of supplying artificial warmth to patients undergoing operation. This incident is not likely to be forgotten at the hospital where it occurred, and its moral will be noted in similar institutions all over the world.

Measles on a "P. and O." Steamer.

AN incident which has been recently recorded in *The Times* on unimpeachable authority points to considerable laxity with regard to infectious diseases in quarters where stringent supervision would naturally be expected. The writer, a well-known London citizen, states that the P. and O. steamship *China* arrived at Colombo from Sydney on February 25th last. On arrival at Colombo the agent allowed a lady and her child suffering from measles to be transferred from another vessel to the *China*. Twelve cases of measles soon broke out on the mail ship. The writer and his servant landed at Marseilles and travelled overland to London. On the journey the servant sickened and developed measles shortly after reaching his destination. The indignation

expressed by the writer is natural, and it is to be hoped that the Peninsular and Oriental Steamship Company will take steps to prevent the recurrence of any similar recklessness in the future. If such a thing can be permitted by that service with regard to one disease, it is not unreasonable to assume that other infectious diseases may be taken aboard with equal nonchalance. The medical officer of the ship from whence the patient came, the agent on shore, the Medical Officer of Health for the port of Colombo, the surgeon of the *Ohina*, and the captain of the latter vessel must all presumably have been aware of the true state of affairs. Who is to answer for this gross oversight? It is no excuse to say that the wisdom of British legislators has failed to place measles on the list of compulsorily notifiable diseases.

Small-pox in London.

THE returns show the usual slight increase in the epidemic of small-pox in the Metropolis. On Wednesday last there were fifty-seven fresh cases; and on Thursday, the 3rd inst., forty-nine fresh cases, making a total of 1,543 under treatment in the Asylums Board hospitals. Since the commencement of the outbreak there have been 958 deaths, and Stepney heads the list with 193 fatalities as against 83 in St. Pancras, which takes second place; 72 in Holborn, 65 in Shoreditch, 59 in Poplar, 53 in Southwark, 50 in Westminster, and so on, down to 7 in Kensington, 4 in Hampstead, and 2 in Chelsea. The disease has broken out in Wandsworth Prison, three cases having been reported to the district medical officer of health. A typical illustration of the way small-pox spreads was shown last week in Upper Clapton. The Medical Officer of Health was called to see the body of a child whom he found to have died from small-pox. The mother and five other children developed the disease, which quickly involved about thirty other persons in the neighbourhood. Not one of the adults attacked had been re-vaccinated. A delirious patient broke out of a special ward on board the *Castalia* in the middle of the night and plunged into the Thames, where he was in all probability drowned. It has been announced that Dr. E. Klein has been requested to undertake an inquiry into hæmorrhagic small-pox on behalf of the Local Government Board.

Mr. Rhodes' Will and the University of Oxford.

THE part of Mr. Rhodes' will which is of most interest to us is naturally that in which he adjures the University of Oxford to place its medical school on a footing "at least equal to that of the University of Edinburgh." As the suggestion is backed by munificent donations and a wholly magnificent scheme for attracting students to this famed and ancient university, it may be that the authorities will take the suggestion into serious consideration. It has long been a matter of surprise and regret that this department of study should have been left, so to speak, under a cloud at this unrivalled seat of learning, but hitherto quasi-medieval influences

have starved it in favour of more "classic" lines of study. When the provisions of Mr. Rhodes' will come into working order a new element, or, rather, several new elements, will be introduced into university life at Oxford, and it is quite conceivable that the changes may have far-reaching effects. Some regret will no doubt be felt that Mr. Rhodes did not see his way to endowing one or some of the other universities which happen to be in greater need of financial assistance than Oxford, notably, the new University of London, which can never attain its proper rank until private munificence has provided the means. No doubt much can be urged in favour of Mr. Rhodes's preference for the residential system, but for obvious reasons the benefits of this system must be reserved for the comparatively few. The nation will hold Mr. Rhodes's memory in grateful esteem, not only because he has greatly contributed to the advancement of study by liberal endowments, but also, and not least, because his benefactions are imbued with a sterling, high-minded patriotism, a patriotism which is not limited by our shores.

Rabelais as a Medical Writer.

THE public have so intimately associated the name of François Rabelais with his satirical writings that his work as a physician and medical writer is almost unknown. He played an important part in the controversy of the sixteenth century that ended in the re-establishment of the Greek medical writers. And it was largely due to his influence that Aldus produced his edition of the works of Hippocrates. It was in Lyons in 1552, then, as now, the seat of a great medical school, that Rabelais commenced his medical literary labours by editing the "Epistles" of Giovanni Manardi, which was followed by his edition of the "Aphorisms" of Hippocrates and the "Ars Parva" of Galen. A little later he published (1565) his "Cinq Lievres de la vie, faicts et dictz Heroïques de Gargantua et de son fils Pantagruel." This edition is recognised by not having the name of the printer on the title-page. It has, however, become very scarce, and at a sale in Paris in the January of this year a copy brought, after keen competition, 2,970 francs. The year after the publication of this work the authorities of the Lyons Hospital suspended Rabelais from his office as physician for having twice absented himself from his duties without leave of absence. The effect of this degradation was to cause him to leave Lyons. Too late they discovered their mistake, but Rabelais could not be induced to return, and some months later Pierre de Castel was elected to the office, in which his complaisant mediocrity made him a favourite.

It has been decided to inaugurate a post-graduate course of Clinical Demonstrations at Westminster Hospital during the coming summer session. The demonstrations will be held on Tuesdays at 4.30 p.m., commencing on May 13th. Particulars thereof will be found in our advertisement columns.

War Office Sweating of Civilian Surgeons.

THE history of the present campaign in South Africa has not been remarkable for anything like a spirit of general parsimony in the expenditure of the War Office. It seems not unlikely, indeed, that the present Boer War will be the costliest that the world has ever known. Money has certainly not been stinted in the matter of Austrian horses or one or two favoured meat contracting companies. When we come to the medical branch of the Service, however, it seems that hardly any economy can be too mean and petty for the authorities of Whitehall. The gross scandals of the hospital and the refugee camps in the South African War have been mainly due to undermanning and to bad organisation of the Army Medical Service. At home the military hospitals by the withdrawal of every available Army surgeon to the seat of war, left gaps that have been filled up by civil surgeons. The latter have been paid at the miserable rate of £270 per annum less the £100 gratuity given to all other branches of the Service. They have also been hopelessly overworked, as there are not enough of them to discharge adequately the duties required of them. At Aldershot the civil surgeons in the military hospitals are being "sweated" with little pay and excessive work in a manner that is discreditable to the nation and likely to be harmful to the patients. A more liberal scale of pay, say £365 per annum, would quickly draw enough competent medical men for temporary service. The miserable rate of pay and the excessive amount of duty demanded in return are not likely to secure the best men available. A few of the many millions that the War Office has handed over to swindling contractors for the purchase of horses and of preserved meat would have put the Army Medical Service on a sound footing both at home and at the seat of war.

Medico-Legal Examinations.

A CASE which has just been tried at Riom, in the Court of Appeal, raises, or rather settles, the question of the right of a defendant in an action for damages by reason of injury to have the plaintiff examined by a medical man deputed for that purpose. The circumstances under which the case came before the Court appear in the *jugement motivé*, in which it is set forth "That Dr. X. accepted the mission to examine the injured plaintiff without any legal authority for so doing and without arranging for the presence of the plaintiff's ordinary medical attendant to be present; that Dr. X. delivered a certificate setting forth the result of his examination in spite of the obligations imposed by professional etiquette as to secrecy, being fully aware that the certificate in question would be made public use of; that Dr. X. violated the domicile of the plaintiff, uncovering her and examining her at his leisure, knowing that she was a married woman, yet without obtaining the authority of her husband so to do . . . all these acts being absolutely deserving of censure not only from a professional but also from a legal point of view."

Poisoning in Antiquity.

THE dexterous administration of poisons for political and social purposes looms large in the history of the Middle Ages and even at periods long anterior thereto. The general public knew little or nothing of the physiological properties of lethal substances however familiar to them the substances themselves might be, and we find accordingly that imagination ran riot and ascribed to them powers and properties which we are unable to reconcile with our present accurate knowledge of the incriminated substances. We dare not scoff too unreservedly at their credulity because even present-day journalists and novelists frequently "give themselves away" when they introduce poison incidents into their writings. Only to mention chloroform it is usually assumed that it is sufficient to sprinkle a few drops of the drug on a handkerchief and hold the same before the intended victim to determine immediate unconsciousness, without further formality, an experience which is strangely at variance with that of the everyday anaesthetist who requires several minutes to achieve his object under the most favourable circumstances. It may be urged of course that the professional poisoners of former times were acquainted with substances the secret of which perished with them, but it is highly improbable that their knowledge included substances unknown to the modern pharmacologist and chemist, and we must dismiss as fables many of the stories which have come down to us from the dark and sinful past in spite of the fact that murder was then considered a fine art.

A Proposed Legislative Fad.

THE United States is the happy hunting ground of the legislative faddist, and if we are sometimes tempted to envy the rigour which the prohibition of certain anti-hygienic practices is enforced, there are occasions on which a doubt suggests itself as to the comfort of living under a perpetual menace of the passage of "crank" bills into law. A New York legislator recently introduced a Bill requiring that in any operation on a woman in hospital three of her nearest relatives must be present and must remain in attendance until all is over. No doubt some other crank will propose an amendment providing for the presence of the relatives at all autopsies on women in order to comply with the inexorable demands of logic. From a medical point of view the proposal does not seem to call for comment, for the inconvenience will fall upon the relatives, few of whom, we imagine, would care to undergo the ordeal of eye-witnessing either operations or autopsies. Should they by some freak of imagination feel impelled thereto they would probably, even now, meet with little opposition, provided, of course, that their behaviour was not such as to disturb the harmony of the proceedings. We doubt, however, whether even the legislature of New York is likely to adopt such an uncalled-for proposal, the object of which it is difficult to conceive.

The Mental Aspects of Lost Property.

Is absent-mindedness a symptom of brain failure? The answer to that question is clearly that it may or may not point to some more or less serious underlying degeneration of the brain tissues, and that in each individual case it must be left to the sufferer to settle the matter with the help of his physician. If the mere leaving behind personal belongings in railway carriages or in cabs and other vehicles, to say nothing of the hundreds of thousands of persons who post letters without stamps, and enclose valuables in letters which they forget to address, were in all cases the result of mental failure then the outlook for the United Kingdom might well be called alarming. To take a portion of one of those groups, namely, the finds for one year in London cabs and omnibuses, as officially reported: this curious list includes 850 sticks, 19,000 umbrellas, 267 rugs, 742 opera glasses, 926 articles of jewellery, 180 watches, 3,239 purses, several dogs, birds, bank-notes and cats. It seems inexplicable how any person could take out a watch in order to leave it lying on the seat of a cab, and no less incredible that a cat should be left behind in a hackney coach. As to the lapse of attention and memory involved in such oversights, they may be due on the one hand to a passing mental pre-occupation or temporary ill-health, or on the other hand they may point to more serious conditions of brain-fag or of failure of nutrition in the brain cells that is of serious import. Any individual who finds that he is acquiring the habit of frequently leaving things behind him in cabs and railway carriages had better go off and consult some physician of experience of disease in its broader aspects. A visit to a brain specialist under such conditions would be apt to be too alarming for the average man in the street.

A Medical Officer on Antitoxin.

COLCHESTER is unhappily divided upon the subject of the value of antitoxin. The city has suffered during the past two years from extensive outbreaks of diphtheria, and in the twelve months ending last December, 209 cases were treated at the Corporation Infectious Diseases Hospital. Dr. Brown, the Medical Officer of Health, is opposed to antitoxin, but has been induced to try that drug owing chiefly to a crusade in its favour instituted by Dr. Hunt and other medical men in the neighbourhood. Dr. Brown has now published in his annual report results of antitoxin in treatment which are distinctly unfavourable to that particular method. He states that the death-rate of patients treated in the hospital with antitoxin has been 15.9, while the death-rate of those treated without antitoxin has been 6.52. He claims for his own treatment of the disease, which consists in clearing off the exudation and false membrane by medicine and local treatment, is safe in action, speedy in its results, and pleasant in its action. This experience is so contrary to the accepted views of most accepted authorities on the subject that it invites serious consideration. If Dr.

Brown be right then Dr. Washbourn and the London Fever Hospital statistics are wrong. If Dr. Brown be arguing from fallacious premises then he is likely to do an almost incalculable amount of mischief to Colchester. In view of the urgent practical bearing of the dispute we suggest that the Local Government Board would do well to institute a searching inquiry into the facts of the case. Such a step should be welcome alike to Dr. Brown and to Dr. Hunt, who can only wish to get at the truth, and would greatly relieve the vexed souls of the Colchester Corporation.

Light Cures.

THE therapeutic effects of light are still without the stamp of scientific approval, although there seems to be good ground for assuming the probability or the possibility of the existence of such results. The single instance where success seems to have been attained is Finsen's phototherapy in lupus, but even that method is open to fallacies, and it cannot yet be regarded as established on an absolutely safe footing. Meanwhile, light is being pressed into the service of the charlatan, who is making a rich harvest by exploiting the virtues of light baths, which are sold to the credulous public at high prices. The light bath as at present made is a hot air bath, and any good result therefrom may be reasonably attributed to the high temperature of the bath, quite apart from the light, to which, however, the therapeutic effect is ascribed. Why do not the vendors of the light bath show that light alone apart from heat, will exert a curative action? Surely the burden of proof lies with them, for otherwise they have merely to add an electric lamp or two to the superheated air bath to get all the advantages of the latter system under the misleading title of a hot-air bath. These appliances are being established wholesale throughout the kingdom for the treatment of disease without the intervention or supervision of medical men. In that way they are calculated to do an immense amount of mischief to the members of the medical profession. The proposed Bill to abolish the right of undertaking medical work by companies would be a great step in the right direction.

The Surgical Treatment of Chronic Bright's Disease.

THE proposal to operate on kidneys affected by Bright's disease for the purpose of relieving the symptoms, if not of curing the condition would have been ridiculed a comparatively few years ago. Though one is scarcely as yet justified in considering it an operation, the usefulness of which is beyond question, enough has been done to prove that it is a subject worthy of the most earnest attention and thought on the part of all medical men. Dr. Primrose has recently recorded (a) an extremely interesting and instructive case in which a boy, aged ten years, who had not reacted satisfactorily to medical treatment directed to the relief of chronic nephritis, was operated on with a satisfactory result up to the

(a) *Canadian Journal of Medicine and Surgery*, March.

time of writing; that is sixty-two days after the last operation. The two kidneys were operated on at different dates. The operation itself consisted in stripping the true capsule from the kidney substance. Full recognition is made of Mr. Reginald Harrison's work on this subject. The last note on the case is to the effect that sixty-two days after the second operation the boy is much stronger than he was, the anæmia has largely disappeared, and the albumin is now a mere trace. A few tube casts could still, however, be found in the urine, but there had been no return of the œdema or ascites.

The Edelmänn "Galton Pfeife."

IN an instructive contribution to the *Edinburgh Medical Journal*, Dr. Macnaughton-Jones describes Edelmann's modification of the Galton whistle, an ingenious contrivance for measuring the acuity of hearing which, in association with the tuning-fork, enables the aurist to distinguish between simple middle ear deafness and defects of hearing arising from an affection of the labyrinth or auditory nerve. Obviously an instrument which enables the aurist to obtain exact records of the hearing for the higher tones is an adjunct of the greatest importance, but it is indispensable first of all to ensure the absolute trustworthiness of the instrument, especially when the point of inaudibility in the highest tones is approximated. This problem was solved by Edelmann by the aid of Kundt's dust figures, a beautiful and tolerably familiar phenomenon, which enabled him to fix with precision the dimensions of the vibrations. This instrument shows that some persons can hear tones of 50,000 vibrations, and a very large number tones of between 37,000 and 40,000 vibrations. In his contribution, which has since been reprinted, Dr. Macnaughton-Jones relates several cases illustrating the application of this instrument to the diagnosis of affections of the organ of hearing which cannot but be of interest to those who make a specialty of this branch of medicine.

The Absence of the Frontal Sinus.

RESEARCHES with the X-rays, undertaken for the purpose of determining the limits of the frontal sinus, have demonstrated the curious fact that in some subjects the sinus is virtually non-existent or is undeveloped on one side. In 240 European skulls Logan Turner found one or both sinuses absent in forty-one (17 per cent.), and in eighteen of these (7.5 per cent.) both were wanting, the proportion of subjects in whom the sinus is totally absent being still higher in the crania of Australian aborigines. It is hardly necessary to point out the grave errors of diagnosis to which these anomalies might give rise if the possibility of their existence were lost sight of. An interesting article on the subject is published in the *Journal* of the American Medical Association for March 22nd, in which the author insists upon the risk of an attempt being made to open a non-existent cavity, entailing the almost inevitable danger of

wounding the dura mater or injuring the brain. We have heard of a case in which this catastrophe actually occurred, and according to the data before us it is feasible in an appreciable percentage of instances.

Mr. Bernard Shaw and Vaccination.

MR. BERNARD SHAW continues to make himself ridiculous in the columns of *The Times* on the subject of vaccination, winding up his last long and incoherent epistle with the observation that "he did not know what to think." It would perhaps have been better if Mr. Shaw had stopped to think before penning his mischievous divagations, for he might then have been able to tell us why we are not to accept evidence as to the protection afforded by vaccination which would be considered conclusive on any other subject. "A Microbe," commenting on his lucubrations, suggests that Mr. Shaw seems to have met with the unhappy fate of the centipede who :—

"Was happy quite,

Until a toad in fun

Said, 'Pray which leg moves after which?'

This raised his doubts to such a pitch

He lay exhausted in a ditch

Not knowing how to run."

A New Application of the Radiograph.

CERTAIN criminals possess great flexibility of their facial muscles, and so modify their expression when being involuntarily photographed in prison that the portrait can hardly be recognised as that of the prisoner when the latter assumes his ordinary appearance. Peace was one of those criminals. At times his face expressed benignity, indifference, shrewdness, and even hatred, just as he wished. To get rid of this trouble the French authorities now require that a radiograph be taken of each prisoner. Whatever power he may have of modifying his facial expression, the criminal has no chance with the radiograph; his bones are not amenable to the influence of his will momentarily exerted during his exposure to this, the latest resource of civilisation for combatting crime.

DR. BARWISE, of Derby, volunteers to subscribe £5 and to collect £100 towards a scheme for a non-vaccination hospital for unvaccinated victims of small-pox. If carried out the scheme would afford interesting data for comparison, and we wish him joy of his project.

THE death is announced of Surgeon-General James Champion Penny, formerly of the Indian Medical Service, at the age of 72. He took part in the relief of both Lucknow and Cawnpore.

PERSONAL.

LORD LISTER celebrated his seventy-fifth birthday on the 5th inst.

DR. JANE BOYES has been appointed parish medical officer for the Island of Coll, Argyllshire, being, we believe, the first lady to be appointed to such a post.

DR. WILLIAM DALE JAMES has resigned the post of medical officer to Sheffield, a post which he has held for the last twenty-two years, in consequence of ill-health.

DR. ALFRED GREENWOOD, of Crewe, has been appointed medical officer for Blackburn, at a salary of £550 a year, in succession to Dr. Wheatley, who has accepted the post of county medical officer of Shropshire.

THE Royal Society of Sciences of Denmark has conferred the membership of that distinguished body on Sir J. S. Burdon Sanderson, M.D., F.R.S., Regius Professor of Medicine in the University of Oxford.

DR. LIEBERMANN LEO, formerly Public Analyst and Medical Officer of Health for Budapest, has been appointed to the Professorship of Public Health in the University of Budapest, rendered vacant by the death of Prof. Josef Tordor.

DR. ARTHUR S. WOHLMAN, of Bath, has received an appointment under the New Zealand Government to advise them in the development of hot mineral springs which they desire to adapt for the benefit of humanity in that distant portion of the globe, on the European model.

DR. NITCH SMITH, of London, had a nasty accident in Victoria Street a day or two since. His horse slipped on the wet asphalt, throwing him heavily to the ground, where he narrowly escaped being run over by a dray. Dr. Smith escaped with a severe shaking and a bruised knee.

MR. H. G. HOWSE, acting president of the Royal College of Surgeons of England, is stated to have accepted the nomination to represent the Council of the College on the Court of Governors of the University of Birmingham. Mr. Howse will only serve for the remainder of the term for which Sir William McCormac was originally elected.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

THE BACTERIOLOGICAL CHAIR BEQUEST TO EDINBURGH UNIVERSITY.

THE trust disposition and settlement of the late Robert Irvine, Fellow of the Chemical Society, was made public last week. The testator directs that certain properties shall be retained or invested until their cash value shall accumulate to the sum of £25,000, or, in the discretion of his trustees, and if they shall think fit, and of which they shall be the sole judges, to the sum of £30,000, and which, exclusive of legacy duty and expenses, they shall then pay over to the Association for the Better Endowment of the University of Edinburgh, or such authorities in connection with the University of Edinburgh as his trustees shall deem expedient, for the purpose of founding a Professorship of Bacteriology in said University, and the equipment of a class-room and laboratory for the teaching of the same and for conducting original investigation in connection with the said subject in which he, the testator, had for many years taken a personal interest; in founding the said Chair he suggested that the University authorities should make such rules and regulations in connection therewith as may promote the study of said science, and for this purpose that nominal fees only be charged for attending the lectures and laboratories in connection with the subject. After providing for the payment of certain legacies, Mr. Irvine directs his trustees to pay the residue as follows:—(1) One-third share to the

Royal Infirmary of Edinburgh; (2) one-third share to the Royal Association for Incurables, Edinburgh; and (3) one-third share to the Dunlop Cancer Fund, Edinburgh.

SMALL-POX IN GLASGOW.

This city, which a year ago was visited with a serious epidemic of small-pox, is again threatened with a return of the scourge, although from the extensive resort to vaccination they had, no fear is entertained that the present outbreak will have a far-reaching effect. Less than two hundred cases have been under treatment, and these were gradually being reduced and fresh cases were fewer at the time of going to press than in the previous weeks. Another case was reported a day or two since at Dundee, but the disease appears not to have taken any hold of this populous centre.

THE MANIPULATION OF MILK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I draw your attention and remark upon the condition of milk supplied to children in your English towns, and how really dangerous such food must be to infants, invalids, and persons of feeble constitution and digestion, when it has to be drugged or late-refrigerated or infused with gases in order to suppress and conceal the state of ferment and decomposition it has lapsed into during the interval of its career from the cow in the country to the consumer in the town.

My experience of milk, its nature, composition and handling is very considerable, and not confined to Belgium, where, however, drugs are strictly prohibited as preservatives. During my recent visit to London I was amazed to read in a copy of your Government Blue Book about an official inquiry upon this subject, and the startling revelations of such an unnecessary, wrong and scandalous practice prevailing in London, to the published estimated extent of 50 per cent. of the milk consumed. No wonder your infant mortality is so great; and this accounts for such sights in your omnibuses and trams of helpless babes suffering untold stomachic troubles from the supply of much fermented milk in bottles forced upon them by their mothers and nurses, ignorant of its nature, as forsooth a method of alleviating their infantine tortures. What more pathetic picture can be imagined? It is a crying shame to send off milk from your country farms that has not been preserved by early-refrigeration down to the non-fermenting temperature of 50° Fahr. or lower, and not conveyed in refrigerated special milk vans, so chilled. The amazing part of the business is, that your meat—not nearly so susceptible to decomposition as milk—is thus refrigerated, conveyed and cold-stored, but not your farmer's milk supply; while to my horror I also learned from your journal, when in London, that your Dairy Farmers' Association were not ashamed of their ignorant habits, but even passed a resolution in support of drugging milk! It is most extraordinary, and discreditable to their intelligence and interests. I also gathered that some kind of scheme was about to be floated for the preservation of milk by infusion of gases (oxygen and carbonic acid gas) Whatever may be the advantages of such a method I am not prepared to state, but the idea of obliging the consumer to absorb milk thus treated is, to say the least, shocking. Why, in the name of common sense, do not your milk producers and distributors supply a pure fresh milk without "messing" it about in this scandalous way, when a proper organisation and the use of ice renders this ideal preservation quite easy? However, perhaps these reflections of a visitor may be of use to mothers or parents, for, in the interests of their children's health, they should demand the instant prohibition of drugs in milk, and also that it should be conveyed from the cow to them in a non-decomposing condition. The science of bacteriology has revealed the activity and breeding of micro-

organisms in milk is suppressed at 50° Fahr., or lower; therefore this should be immediately attended to at once on its being drawn from the cow; for a further fact is that at animal warmth rapid fermentation prevails. All this can be easily and simply accomplished. It is done in this country, and almost universally in America, and your authorities should insist upon a reform being carried out in connection with your milk traffic.

I am, Sir, yours truly,

L. J. SERIN,

A.E. State Agricultural Expert.

Montsur, Marchienne, Charleroi (Belgium),

April 2nd, 1902.

THE SWALLOWING OF A METALLIC DENTURE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The interesting description of "swallowing a metallic denture" and its successful transition along the entire alimentary canal, recorded by Dr. G. Jameson Johnston, in your issue of Wednesday last, recalls to my memory a similar accident which occurred to a patient of mine twenty years ago. The notes of this case, together with an accurate drawing of the vulcanite plate (made to scale), with two artificial teeth and a sharp gold hook attached, were published in the *Lancet* of December 10th, 1881. At that time it was considered from its size and inequality to be one of the most formidable foreign bodies which had safely accomplished such an inconvenient journey. In comparing the two representations which are now before me I think the measurements are almost identical; if anything, mine is a trifle the larger of the two, but the difference is so slight that it is hardly worth mentioning. A few days after the publication of my case the conservator of the Royal College of Surgeons (the late Sir William Flower) wrote to ask me to present the plate to the College museum, where it can now be seen.

The treatment I adopted on that occasion was chiefly expectant. I forbade all liquid food except a little bread and milk, kept the patient strictly at rest in bed, and told her to eat plentifully of suet pudding and boiled rice. On the second day following the accident I administered a small dose of castor oil as a gentle laxative. Within a few hours afterwards she passed a copious evacuation in which the plate was discovered enveloped in a mass of fecal matter completely protecting the structures from injury, and voided apparently without pain or inconvenience.

I am, Sir, yours truly,

FREDERICK S. PALMER, M.D.

7, Gordon Place, Gordon Square, London.

NATALITY IN GREAT BRITAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There are always two sides to a question, and my own experience leads me to hold views somewhat different from those so ably expressed by "A Student of Sociology" in your last issue. He assumes that a high birth-rate is indispensable to the success of nations, and, apparently, to the welfare of the individual. I venture to suggest, however, that both premises are founded on misconceptions. To the average individual an unrestricted output (of children) means a life of unremitting and often thankless labour, associated with endless worry and tribulation. The numerous members of such a family can receive but a minimum amount of education, primary, secondary or technical, and they have to "scratch round" as soon as they are capable of independent effort. The effect on the mother of repeated child-bearing at short intervals—a necessary consequence of the patriotic abandonment of control—is often disastrous, and she can devote but scant attention to the older children owing to the claims on her time and attention of the later arrivals. The limitation of families, on the other hand, establishes some sort of proportion between the parental sources and the demands upon them. The children are better

cared for, better educated, and obtain a better start in life.

The tendency to the limitation of offspring is not confined to any one country. It is manifested more or less in all civilised communities. Even in a new country like the United States the birth-rate is stated to be barely equal to the deaths. It appears to be a natural process incidental to the life-history of the globe, or at any rate to the evolution of civilisation. The subject undoubtedly is beginning to attract the close attention of the general public, and parents now arrogate to themselves the right to decide the conditions of their existence.

The columns of a medical journal are obviously the best place for a discussion of this kind on account of the physiological trend of many of the arguments.

I am, Sir, yours truly,

QUEERNS.

Obituary.

EDWARD LONG FOX, M.D. OXON., F.R.C.P.

WE regret to announce the death of Dr. Edward Long Fox, which took place on Friday, March 28th, at his residence, Clifton Park, after an illness extending over some months. Dr. Edward Long Fox was born at Brislington, near Bristol, in 1832, his father, Dr. Francis Ker Fox, being the head of the Brislington House Private Asylum. He was educated at Shrewsbury School, under the Rev. Benjamin Kennedy, D.D., who was afterwards Professor of Greek at Cambridge. He afterwards went to Balliol College, Oxford, and had Professor Jowett as tutor, where he obtained his first-class in natural science tripos. He pursued his medical education at St. George's Hospital, Great Ormond Street, and the Brompton Hospital for Consumption. He settled in Bristol in 1857, and was immediately appointed physician to the Royal Infirmary, a position which he held for twenty years, when he was promoted to the consulting physicianship. In 1892 he delivered the Bradshaw lecture at the Royal College of Physicians, having been elected a fellow in 1870. For some years he was lecturer on the Principles and Practice of Medicine, and for several years he acted as Examiner in Medicine at the University of Oxford, and he was lecturer on medicine and pathological anatomy at the Bristol Medical School. He was physician to Clifton College for many years during the head-mastership of Dr. Percival. He was a past president of the Bath and Bristol branch of the British Medical Association and the British Medico-Chirurgical Society. When the British Medical Association visited Bristol in 1894, Dr. Long Fox was its president.

Dr. Fox was also president of the National Temperance League in 1894, and for several years was actively engaged in temperance reform, personally working in the parish of St. Jude's. Though very enthusiastic in his advocacy of the temperance cause, his natural liberal-mindedness prevented his taking any narrow view of the problems to be solved.

His published works included "The Pathological Anatomy of the Nervous Centres," and "The Influence of the Sympathetic on Disease." He contributed a series of papers to the *Medical Times and Gazette* on "The Temperature in Acute Diseases," and also was the author of various articles in "Quain's Dictionary of Medicine," an article on "The Sympathetic" in the "Dictionary of Psychological Medicine," and many articles in the *British Medical Journal*, *Lancet*, &c. Dr. Fox married Miss Bradley, one of the daughters of the late Rev. Charles Bradley, of Clapham, sister of the present Dean of Westminster, and leaves one son and several daughters.

SURGEON-CAPT. GEORGE RAMSAY, I.M.S.

INTELLIGENCE has just come to hand of the death of Capt. G. Ramsay, of the Indian Medical Service, residency surgeon at Baghdad, from heart failure, after a severe attack of fever, at the early age of thirty-three. He was the eldest son of the late Mr. W. Ramsay, of the

Bombay Civil Service, retired, was born in October, 1868, was educated at King's College Hospital Medical School, and admitted a member of the Royal College of Surgeons and a licentiate of the Royal College of Physicians, London, in 1892, subsequently filling the post of house surgeon at King's College Hospital, and in 1894 entered the Indian Medical Service. He also served in the Chitral Expedition, for which he had the medal with clasp, and has recently been officiating as residency surgeon and *ex officio* assistant Political Resident at Baghdad.

New Article.

TOILET ARTICLES IN PAPER.

THE usefulness of paper for many toilet purposes, although generally recognised, has not, with one exception, been turned to much account. We are convinced, however, that a short experience of these substitutes for linen, &c., would establish their superiority in point of cleanliness, neatness and economy. We have received from The Toilet Novelties Co., Bristol, sundry samples of articles manufactured by them. Among these we find an assortment of "Toilet Pocket Books"; one kind, put up in a very compact and convenient form, is euphoniouly described as "lavatory paper," and it may fairly be described, in every respect save the price, which is moderate, as an "article de luxe." Both hygienically and æsthetically these pocket books are preferable to nondescript substitutes, and if they have not already been adopted by Royalty, they deserve to be.

Other pocket books, of larger size, contains leaves of "silky fibre" paper suitable for use as pocket handkerchiefs or to receive expectoration with a view to subsequent destruction by fire. They are beautifully soft, although possessed of considerable resistance.

The napkins, or serviettes, made of a specially soft English paper, of crêpe texture, commend themselves to the notice of economical and stylish housekeepers. Their very novelty is a recommendation, and by the time the novelty has worn off the more solid advantages attending their use will have been appreciated. Some of them are artistically figured with cambric-like designs, and are elegant in the extreme.

No travelling outfit can be regarded as complete which does not comprise an adequate supply of these eminently portable and cleanly conveniences.

Medical News.

School of Physic - Trinity College, Dublin.

A COURSE of ten lectures, illustrated by lantern slides, will be delivered in the Anatomical Theatre, Trinity College, commencing Monday, April 14th, 1902, at 4.30 p.m., and continued upon the following Wednesdays, Fridays, and Mondays, at the same hour, on "Diseases of the Rectum," by Charles B. Ball, Regius Professor of Surgery, University of Dublin. The course will be open free to qualified medical practitioners, upon production of their cards. A limited number of fifth year's students will also be admitted by ticket, which may be obtained on application to Professor Mackintosh, Trinity College; Professor Fraser, Royal College of Surgeons; or Professor Birmingham, Catholic University School.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness Annuity and Life Assurance Society was held at 429, Strand, London, W.C., on the 26th ult. There were present: Dr. de Havilland Hall, in the chair; Dr. J. B. Ball, Mr. J. Brindley James, Mr. H. P. Symonds, Dr. M. Greenwood, Dr. F. R. Mutch, Mr. F. S. Edwards, Dr. F. S. Palmer, Dr. St. Clair B. Shadwell, and Dr. F. J. Allan. The Committee examined a long list of sickness claims, but they were for the most part of a light nature, and not likely to make any heavy demand on the ample resources

of the Society. A considerable number of new entrants was also reported, and it is gratifying that, notwithstanding the large number of members who necessarily drop out as the age of the Society increases the influx of new members more than fills up the gaps thus caused, and the total number of members grows year by year. As the Society spends no money in advertisement this growth is entirely due to the efforts of the members in bringing the advantages offered to the notice of their medical friends and, combined with the fact that an ever increasing number of members apply to have their sickness benefits increased to the limit allowed, £6 6s. per week, is good evidence that they appreciate the work the Society is doing. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33 Chancery Lane, London, W.C.

A Risky Proceeding.

MR. ANDREW ROSTANT, a Tottenham practitioner, was summoned on the 3rd inst. to answer a charge of sending a man suffering from small pox with the certificate under the Notification of Infectious Diseases Act. The man was diagnosed to be suffering from small-pox, and Mr. Rostant handed him the certificate, telling him to leave it with the medical officer of health on his way home. He went there and sat down in the surgery with a number of other patients. It was elicited in evidence that he afterwards remained a fortnight at home owing to lack of hospital accommodation, a fact which does not say much for the way in which they administer the sanitary laws in the Tottenham district. Ultimately the Bench dismissed the charge, remarking, however, that it was a suitable case for an appeal.

Sudden Deaths.

DR. FRANK ILIFFE, of Derby, was found dead in his bed last week without any previous admonition of ill-health. Dr. Iliffe qualified in 1861. Dr. Bailey, one of the leading practitioners at Crewe, died suddenly in a patient's house last week, having been taken ill in the street. Dr. Bailey was medical officer of health, a town councillor, and a justice of the peace.

Dublin Death-rate.

THE deaths registered in the Dublin registration area for the week ending Saturday, March 29th, 1902, represent an annual rate of mortality of 29.0 in every 1,000 of the population; 53 deaths resulted from disease of the respiratory system; 20 from diseases of the circulatory system.

In 12 instances the cause of death was "uncertified," there having been no medical attendant during the last illness.

Forty-nine infants, 30 of whom were under one year old, died during the week.

Within the city proper the death-rate was as follows in the Clarence Street, Carte Street, and Grand Canal Street districts, 33.1, 39.6, and 35.9 respectively.

Pass Lists.

Society of Apothecaries of London.

THE following candidates passed the Primary Examination, Part I.—April 2nd and 3rd, 1902:—

Biology.—S. F. H. Everill, C. E. Pring.

Chemistry.—S. F. H. Everill, J. C. Fletcher.

Matéria Medica and Pharmacy.—M. S. Jevons, T. Lea, J. G. Lewis, E. H. Price, E. Sergeant.

The following passed the primary examination, part II.:—

Anatomy.—G. H. Almond, A. Bernfeld, E. P. J. Dawes, L. Doudney, A. G. C. Findlay, A. G. Gamble, H. S. Gettings, G. P. K. Grey, C. Homer, L. J. Paterson-Clavier, J. W. Peatt, J. O. Sergeant, F. A. K. Stuart, E. J. C. Thompson, J. A. R. Wells, P. B. Whittington.

Physiology.—A. Bernfeld, L. Doudney, F. C. M. Gabites, H. S. Gettings, J. C. Johnson, J. G. Lewis, G. B. Messenger, L. J. Paterson-Clavier, J. W. Peatt, E. J. C. Thompson, J. A. R. Wells, P. B. Whittington.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

A CERTAIN CURE AND PREVENTIVE OF SMALL-POX!

A CORRESPONDENT forwards us the following letter, which was sent to the manager of a large industrial undertaking in London:—

The Flour Mills, Hildersham, Cambs.

Sir,—I beg most respectfully to offer you a splendid recipe for the prevention of small-pox—that dreadful complaint for the sum of 21s., which sum I paid to an old lady in Gloucestershire, three years ago, and who died about two months ago at the old age of 106 years. She was a very clever old woman in such things. She told me it was a positive prevention, and in ninety-nine cases out of a hundred a cure for the same, and that it would prevent me or anyone from catching that dreadful complaint. I may add I am a perfectly honest man, and in good faith I offer you this, thinking that in your position it might be of some use to you. Trusting I shall not give offence in offering you this,

I remain, Sir, yours most respectfully,
J. KEMP.

BATHYBIUS.—In reply to this correspondent in our last issue, D.K. writes that he has a perfectly new galvanic battery by best maker, which he purchased a month ago, but has not used it and has now no need for it, with twenty four dry cells, reverser and regulator. This he is willing to dispose of to *Bathybius* at the reduced price of £1 10s. Particulars of which can be had by addressing D.K., care of publisher.

VARIETIES OF IPECACUANHA.—The following are some of the recent variations received in the popular orthography of this useful domestic remedy:—"Iipquance," "ekyoupekyuana," "impecunia," "epicaquany."—*Chemist and Druggist.*

DR. F. S. W. HOGG.—We regret that we are unable to give you the reference you ask beyond the fact that the article was based on a paragraph in one of our American exchanges.

LORD LISTER.—BORN APRIL 5, 1827.

THE *Daily Chronicle* publishes the following on our illustrious confrere's birthday:—

Whose knowledge claimeth at the helm to stand.—**BROWNING.**
This is the prince of leeches; fever, plague,
Cold rheum and hot podagra, do but look on him.
And quit their grasp upon the tortured sinews. **SCOTT.**
Batting with custom prejudice, disease
As once the son of Zeus with Death and Hell.—**W. E. HENLEY.**
There was none like him in the wide world's throng
To speak of physis and of surgery.—**CHAUCKER.**
The evil is half-cured whose cause we know. **CHURCHILL.**
To thee
Our gratulations flow in streams unbounded.—**HENRY CARR.**

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, APRIL 9TH.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Clinical Evening.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

SANITARY INSTITUTE (Parkes Museum, Margaret Street, W.).—8 p.m. Discussion on the Prevention of Malaria. To be opened by Dr. Patrick Manson.

THURSDAY, APRIL 10TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, W.).—8.30 p.m. Papers Dr. R. Bowles: The Practical Treatment of Functional Vasomotor Disturbances.—Mr. Raymond Johnson: Some Points in the Treatment of Tuberculous Disease of the Knee.

BRITISH GYNECOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Dr. H. Macnoughton-Jones: Specimens.—Dr J. Halliday Croome: On the Secondary Aspects of Decidua Malignum.

FRIDAY, APRIL 11TH.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi Terrace, W.C.).—7.30 p.m. Discussion on the Tenure of Office of Medical Officers of Health.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—5 p.m. Cases and Specimens will be shown by Dr. Wyatt Wingrave, Dr. W. H. Kelson, Dr. St. Clair Thomson, Mr. A. H. Cheate, Dr. Lack, and others.

CLINICAL SOCIETY OF LONDON (20, Hanover Square W.).—8.30 p.m. Mr. Thomas Cawardine: Cases illustrating the Mode of Origin of certain Cysts of the Neck.—Dr. J. W. Tyson: Case of Intestinal Obstruction due to Embolism of a Branch of the Superior Mesenteric Artery.—Mr. A. E. Barker: Cerebellar Abscess with Sudden Paralysis of the Respiratory Centres.—Mr. H. L. Barnard: The Simulation of Acute Peritonitis by Pleuro-Pneumonic Disease.

DUBLIN.

FRIDAY, APRIL 11TH.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Medical Section.—Exhibits: Dr. J. B. Coleman (a) Case of Sporadic Cretinism (b) Case of Bradycardia. Papers: 1. Mr. R. Fobin: Some Medical Aspects of Four consecutive Cases of Perforated Gastric Ulcer successfully operated on. 2. Dr. Parsons: A Case of Ascending Para-

lysis. 3. Dr. O'Carroll. (a) Two Cases of Ascending Paralysis (b) A Case of Cerebro-Spinal Meningitis. 4. Dr. J. B. Coleman: Notes on Some Cases of Nervous Diseases. Royal College of Physicians. 8.30 p.m.

MONDAY, APRIL 14TH.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—Second Professional Examination.

Appointments.

BOYES, JANE, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Medical Officer for the Island of Coll, Argyllshire.

EVANS, ARTHUR, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to Westminster Hospital.

GREENWOOD, A., M.D. Vict., Medical Officer of Health of Blackburn.

HUNTER, MITCHELL, M.D. Miami Med. Col., L.S.A. Lond., Certifying Surgeon under the Factory Act for the Magherafelt District of the county of Londonderry.

LLOYD, F. S., M.B. Lond., Certifying Surgeon under the Factory Act for the Luton District of Bedfordshire.

MACVIE, A., M.D. Edin., Medical Officer of Health by the Baildon Urban District Council, Yorks.

MCLEAN, J. C., M.B., CM. Edin., Medical Officer of Health by the Doncaster Rural District Council.

MOSSOR, A. G., M.R.C.S., L.R.C.P., L.R.C.S. Irel., Medical Officer of Health by the Newhaven Port Sanitary Authority.

NETTLE, WILLIAM, M.R.C.S., L.S.A., J.P., Medical Officer of Health by the Liskeard Rural District Council.

NICHOLLS, JOHN MICHAEL, L.R.C.P. Lond., M.R.C.S., J.P., Medical Officer of Health, of St. Ives, Cornwall.

PALLETT, T. E., L.S.A. Lond., Certifying Surgeon under the Factory Act for the Earl's Colne District of Essex.

PEARSE, JAMES, M.D., CM. Edin., Medical Officer of Health of Trowbridge, Wilts.

SAUNDERS, LEONARD DOUGLAS, M.R.C.S. Eng., L.R.C.P. Lond., House Surgeon to the Hastings, St. Leonards, and East Sussex Hospital, Hastings.

SHAW, A. H. P., M.R.C.S., L.R.C.P. Lond., Medical Officer of Health of Fritenden.

THOMAS, J. TELFER, L.R.C.P. Lond., M.R.C.S., Medical Officer of Health for Camborne, Cornwall.

Vacancies.

Ballinasloe Union.—Medical Officer for Kiltormer Dispensary District Salary £120 per year, with registration and vaccination fees. Also, a Medical Officer of Health for the Ballinasloe No. 1 Rural District. Salary £15 per year. Immediate application to R. J. Gill, Clerk of Union. (See Advt.)

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160. Applications to the Honorary Secretary, Joseph Carr, 41, Mosley Street, Newcastle-on-Tyne.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160 per annum; furnished apartments, attendance, light and fuel are found. Applications to Secretary, M. I. Preston, Journal Chambers, Nottingham.

Portsmouth Borough Asylum.—Assistant Medical Officer. Salary £120 per annum, with board, lodging, &c. Applications immediately to the Medical Superintendent.

Rainhill County Asylum, near Liverpool.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Births.

BLYTH.—At Burnford House, Attercliffe Common, Sheffield, the wife of James Blyth, M.B., CM. Edin., of a daughter.

COLEMAN.—On April 3rd, the wife of J. G. B. Coleman, M.R.C.P. Eng., L.R.C.P. Lond., of a son at Sutton Bridge, Wisbech.

ETHERIDGE.—On April 3rd, at Tankerton, Whitstable, the wife of C. E. Etheridge, M.B. Lond., of a daughter.

HOLDEN.—On April 6th, at 168 Castle Hill, Reading, the wife of George Herbert Rose Holden, M.A., M.D. Cantab., of a son.

MACMILLAN.—On March 3rd, at Mossall Lodge, Prestwich, the wife of D. Macmillan, M.D., of a son.

SHAW.—On Easter Day, at 32, New Cavendish Street, Cavendish Square, London, the wife of John Shaw, M.D. Lond., M.R.C.P., of a daughter.

STORRS.—On April 5th at Springfield, Chelmsford, the wife of Kenneth S. Storrs, M.B. Camb., of a son.

Marriages.

COLLINSON-CLARKE.—On April 3rd, at St. Alkmund's Church, Derby. Frederick Wil iam Collinson, M.D., of Preston, to Clara, daughter of the late Thomas Clarke, of Derby.

WALTERS-BATTOCK.—On April 3rd, at Luke's Church, Maidenhead. James Hopkins Walter, M.R.C.S., L.S.A., of Reading, to Hyda Margaret Vowe, younger daughter of George Arthur Battcock, of Ambler House, Maidenhead, Berks.

Deaths.

CHILTON.—On April 2nd, at 14, Cambridge Park, Reginald Horace Chilton, M.R.C.S., L.R.C.P., third son of G. H. D. Chilton, Esq., Under-Sheriff of Bristol, aged 31.

FOX.—On April 2nd, at Brislington House, near Bristol, Esauville Bradley Fox, M.D., son of the late Francis Ker Fox, M.D., aged 49.

HUGHES.—On April 3rd, suddenly, at Dublin, Richard Hughes, M.R.C.S., L.R.C.P., M.D., of Albury, Guildford, late of Brighton, in his 68th year.

PENNY.—On April 3rd, at 6, Nevren Square, London, S.W., Surgeon-General James Champion Penny, M.D. Lond., aged 72.

Original Communications.

ON THE LIGATION OF THE EXTERNAL ILIAC ARTERY FOR ILIO- FEMORAL ANEURYSM AND OTHER TUMOURS. (a)

By H. G. CROLY, F.R.C.S.I.,

Surgeon to the Royal City of Dublin Hospital, Past-President of
the Royal College of Surgeons.

I WISH to bring under the notice of this Section of the Royal Academy of Medicine three cases of ligation of the external iliac artery, one performed recently for ilio-femoral aneurysm, the other two to facilitate the removal of malignant growths in the groin and to safeguard the patients from sudden and fatal hæmorrhage. Before detailing the cases, and in order to make the subject of my communication more interesting, instructive and practical, I shall refer as briefly as possible to the surgical anatomy of the external iliac artery with special reference to the relation of its accompanying vein, the surrounding sheath, the position in which the branches are given off, and, in my opinion, the proper site to select for the application of the ligature to the artery.

The external iliac artery takes an oblique course downwards, outwards and forwards, indicated by a line extending from the left of the umbilicus to the centre of Poupart's ligament—its length is from 3½ to 4 ins., it lies on the psoa-iliac aponeurosis, and psoas muscle. The peritoneum covers the artery completely above and on its inner side through the greater part of its course. The ureter, especially at the right side, dips into the pelvis internal to the artery close to its origin. The external iliac vein, at the crural arch, is internal to the artery, and nearly on the same level and separated from the artery by a septum—as the vein ascends it is internal and gradually becomes posterior to the artery, and lies on a plane internal to the pelvis, its outer edge looking somewhat upwards and outwards; still higher the vein gets posterior and lies in the interval between the bifurcation of the common iliac into external and internal iliac. The genito-crural nerve lies to the outer side of the artery, sometimes enveloped in the sheath, and at the lower part of the artery the genital branch passes in front of the artery.

The artery and vein are invested by a cellular membrane—fascia propria or subperitoneal fat, also called Abernethy's fascia—it is joined to the fascia iliaca at either side of the vessels, and I have

demonstrated a process of the sheath or fascia propria passing between the artery and the vein so that the artery can be ligatured without the vein appearing. One or more oblong lymphatic glands are situated close to, or anterior to, the external iliac artery near its termination and where it is crossed by the spermatic vessels, also by the circumflex iliac vein. The artery at the right side has the termination of the ileum and the cæcum in close relation. The external iliac artery gives off no branches of importance until within a quarter or half an inch of its termination. It then gives off from its outer side the anterior or circumflex iliac, and from its internal or anterior surface the deep epigastric artery. It is therefore quite obvious that the lower portion of the artery should never be selected for tying.

Case I.—ILIO-FEMORAL ANEURYSM.—P. K., æt. 42, residing near Dublin, driver of bread cart, served as gunner in the Mounted Train Battery, Royal Artillery, for eight years, during the Egyptian campaign, had syphilis twelve years ago. Cicatrix in left groin where bubo was opened, has been a moderately hard drinker. Except for the illness alluded to he enjoyed good health. Consulted me in April, 1901, for a swelling in his right foot, leg and thigh, which he attributed to jumping up and down off bread cart. He said the swelling commenced in his ankle and gradually went up his leg and thigh to his groin. On examination of the affected limb it was swollen not unlike phlegmasia alba dolens. There was no pitting on pressure. No glandular or other swelling in groin. There was an erysipelatous blush on the front of the leg. He was placed in one of the observation wards; limb elevated; warm boric stupes applied; the swelling gradually disappeared and he was sent to the Convalescent Home, where he remained a fortnight and then feeling quite well he returned home on May 17th, resumed his work on the bread cart, exactly one month from the day I first saw him. The day after he resumed his work he felt a stiffness in his right groin, and as he did not get relief from resting at home he came in to see me on June 3rd. I examined his groin and limb, and found nothing except a slight enlargement in the thigh. He was again admitted into the Convalescent Home, where he remained resting the limb for twelve days. June 17th he came in to consult me, when I at once detected an ilio-femoral aneurysm. At that time all other swelling had left his leg and thigh.

Treatment.—He was placed in a very comfortable bed. Tufnell's diet and iodide of potassium were prescribed and carried out. A flannel bandage was applied from the foot to the knee and an ice-bag was applied to the tumour. Perfect rest and instrumental and digital pressure got a full trial. The tumour, which occupied about the circumference of a small orange, gradually enlarged, pulsated strongly, and there was a very distinct *bruit de souffle* heard

(a) Paper read, and casts and photographs shown, before the Surgical Section of the Royal Academy of Medicine on April 4th, 1902.

over it. The patient carried out all instructions in a most praiseworthy way.

The patient was naturally anxious, as indeed I was, to give the treatment by rest, pressure, diet, and medicine every trial before resorting to operation. The tumour as seen by the cast extended from the pubic spine close to the crest of the ilium, and extended downwards below the origin of the profunda femoris; it could be felt dipping into the pelvis. I was out of town for a holiday during September, and on my return I was pleased to find the tumour much firmer at the circumference, and smaller. The patient's health was excellent. He did not suffer in any way from the long confinement to bed, and at no time did the skin become irritated, as the part was kept constantly shaved and dusted. At one time in October the aneurysm showed signs of being cured, but the pulsation returned as forcibly as ever, and then the patient expressed a strong desire to have the operation performed. I operated on October 31st last year.

I weighed carefully in my mind all the facts of the case—the possibility of the aneurysmal tumour extending into the pelvic cavity, and the artery being diseased high up. The operation known as Abernethy's I never liked; the one modified by Sir A. Cooper I thought unsuitable for the case. I therefore decided to make my incisions in such a way as to give plenty of room to go high on the artery, and if necessary to ligate the common iliac. There is no tendency to hernia, and nothing remains at the site of the aneurysm except a small hard mass, with gland-like feet.

The skin wound was not deepened in the vicinity of the internal abdominal ring, and the deep epigastric therefore was not endangered. The fascia transversalis was opened to the outer side of the "deep ring"; the internal oblique and transversalis were separated low down; the cæcum and small intestine were drawn up by means of a broad spatula made specially for Professor Hargrave's case of ligation of common iliac (at which I was his chief assistant). When the intestines in the unwounded peritoneum were drawn well up I saw the aneurysmal sac dipping into the pelvis. The whole length of the external iliac artery enclosed in its sheath was exposed, not a drop of blood was seen, and the parts looked so like an operation on the dead body that I said so at the moment (on looking into the various papers since my operation I find that Sir Philip Crampton made a similar remark at his operation on the external iliac).

The external iliac in its strong sheath *did not pulsate*. I placed my finger on the vessel and felt its pulsation. I raised portions of the sheath with a fine pointed forceps, and cleared with a small scalpel a sufficient space to allow a long-handled aneurysm needle to pass round the artery from within outwards. The *vein was not seen* and no nerve came into view. The needle was threaded with ox peritoneum (gold beater's skin) the loop being held, the needle was withdrawn, the loop divided leaving a double ligature under the vessel, the ligature on the cardiac side was tied first by first half of reef knot; the artery which was very large, but *normally soft*, grooved like a director as I approximated by *Scarpa's method* the internal coats of the artery; the second ligature was then tied in a similar way, then the two ends from each side, treated as a single ligature, were tied, thus completing the stay-knot of Ballance and Edmunds. When the first knot was tied all pulsation in the aneurysm ceased and never returned. The tumour, though silent, did not alter in size, showing that there was a very considerable amount of fibrin deposited in the sac, the result of pressure and rest.

The patient bore the operation well, and for about four hours after his removal to bed he complained of a numb sensation in his foot. That passed off, and he never complained of any discomfort afterwards.

Ureter peels off with the peritoneum.

The patient made an uninterrupted recovery, and is at present in the enjoyment of perfect health. Through the courtesy of Dr. White, curator of the museum, three casts were taken by the museum porter. The first shows the size and extent of the aneurysm, the second shows the change after operation, the third shows the present condition of the limb. When the trunk of the external iliac artery is ligated the limb is abundantly supplied with blood by the branches of the internal iliac which leave the pelvis. The gluteal transmits blood to the femoral artery through the internal and external circumflex branches of the latter.

The sciatic transmits blood to the femoral artery by the internal circumflex and perforating arteries, and to the popliteal through the cava nervi ischiatici. The obturator supplies the femoral through the branches which communicate with the internal circumflex, and the pudic artery supplies the femoral by its communication with the pudic branches of the latter.

Examination of limbs where the cases ended fatally the portion of the femoral artery below the origin of the profunda was found to be normal. The portion between the ligature and origin of the profunda was normal or reduced to one-half its size. Case of Sir Astley Cooper.

The case just detailed of spontaneous ilio-femoral aneurysm is full of interest, and the highly satisfactory termination is, in my opinion, in no small degree attributable to the preparatory course to which the patient was subjected, namely, perfect rest, Tufnell's diet, digital and instrumental pressure, which gave time for fibrinous deposition in the very large sac and the establishment of a free collateral circulation.

Mr. Charles H. Todd, one of the surgeons to the Richmond Surgical Hospital, reported cases of popliteal aneurysm in which operations were performed in the "Dublin Hospital Reports," vol. iii., 1820. The tumour was so much under the control of pressure on the inguinal portion of the artery that I was not altogether without hope that by *diminishing* the current of blood in the trunk of the artery so as to favour the coagulation of the contents of the sac a cure *without operation* might be effected; at all events it was obvious that by giving time to the collateral arteries to be dilated the success of the operation would be rendered less uncertain.

A preparatory course recommended previously to operating for aneurysm.

The cases of popliteal aneurysm (says Todd) are chiefly related with a view of recommending a more general adoption than is at present practised of a preparatory course previously to operation.

I can scarcely doubt but that in many cases of aneurysm in which operations have failed from mortification of the limbs succeeding, the patient might have been saved by a delay sufficient to allow some progress to be made in establishing the collateral circulation, and I feel confident that this desirable object may be promoted in most instances of recent disease situated at a sufficient distance from the trunk by compressing the principal artery of the limb for a few hours every day for a period which must vary according to the circumstances of the case.

CASES OF LIGATION OF THE EXTERNAL ILIAC ARTERY AS A PRELIMINARY TO REMOVAL OF MALIGNANT GROWTHS FROM THE GROIN.

Case I.—A young man employed in a butcher's

shop in Baggot Street came under my care suffering from a melanotic sarcoma in the groin. I laid bare the external iliac artery by Sir Astley Cooper's incision, ligatured the external iliac and deep epigastric, finding the femoral artery in the centre of the growth. I tied that artery also below the profunda and removed the entire growth. The circulation in the limb was thoroughly established. The patient developed melanotic growths over his abdomen and chest, and died from exhaustion in some months.

Case II.—A young man was admitted into hospital last year under my care suffering from a large watery ulcer of cicatrix on his leg. I removed the limb above the knee and the stump healed. In a short time the glands in the vicinity of the saphenous opening became enlarged and were excised, a large growth soon followed. I ligated the external iliac artery, and cleared all the growth from the groin and pelvis. A fresh growth was rapidly developed at the opposite side. The patient was admitted into the Royal Hospital for Incurables, where he died a few months since from exhaustion.

The following truly sad case led me to decide on ligating the external iliac in malignant growths in the groin:—

A young clergyman from the country consulted me some years ago for an ulcer on the prepuce, which I at once pronounced to be malignant; the growth was removed and the part healed satisfactorily. The patient returned home and resumed his duties; in a few months he returned to town with a glandular enlargement in his groin. I removed the glands; the wound healed and the patient returned again to his duties. In a few months he returned to consult me and I was horrified to see a huge mass of cancer occupying the groin and dipping into the pelvis. I advised the unfortunate sufferer against any further operative interference. This opinion was confirmed in consultation with a late distinguished senior member of the profession.

The patient remained near town, where I saw him occasionally. Small bleedings occurred from time to time. One day I was sent for in great haste, and when I got to the house I found the patient dead; sudden arterial hæmorrhage flooded the bed.

I at once made up my mind if I met such cases again to ligate the main artery on the same principle as I adopt in tongue cancer of cutting off the main blood supply and prevent sudden death from hæmorrhage.

HISTORY OF THE OPERATIONS ON THE EXTERNAL ILIAC ARTERY.

Mr. Abernethy is said to have been the first surgeon who tied this artery (in the year 1796) for femoral aneurysm. He had previously tied the femoral on the distal side of the aneurysm (Brasdon). Severe secondary hæmorrhage set in on the fifteenth day. He made an incision over the course of the artery. He experienced much difficulty until the fascia (? sheath) which covered the artery and vein was opened. In his second case he made his incision not over but a little external to the artery. Both cases ended fatally. In 1806 Abernethy had a successful case. Mr. Abernethy's operation was condemned at the time as a rash and useless operation, whilst some disbelieved that it was ever put into execution. Mr. Abernethy's cases showed that it was an operation highly justifiable, and he afterwards had the gratification of seeing it successfully practised.

Freer, of Birmingham, performed the operation in 1806; Tomlinson in 1807 and 1809; in 1811 Kirby, of Dublin, had a successful case. He is said to have experienced the same difficulty from the subperitoneal fascia as Abernethy. Sir Astley Cooper, in 1814, had seven cases; four were successful, three died.

The external iliac artery has been tied in Dublin by Todd, Wilmot, William Henry Porter, Houston and Bellingham.

Dupuytren lost his case by wounding the epigastric artery, Bécларd by tying immediately below its origin.

Travers' well-known case was lost in consequence of the ligature having been placed on the artery between the epigastric and circumflex ilii. In 1810 the external iliac was tied for the first time in France by Delaporte, of Brest. The patient died. Goodlad had a successful case in 1811, and Dorsey, of Philadelphia, another in the same year. In 1812, Bouchet, of Lyons, operated with success. The same year, Albert's case died of tetanus. Mr. Norman and Mr. Brodie had each a successful case in 1813, and Lawrence in 1814. Mr. Samuel Cooper states that out of twenty-five cases gangrene occurred in three—one of Sir A. Cooper's, second Bouchut of Lyons, the third Mr. Collier's. Arendt tied both external iliacs in succession, with an interval of eight days only between the operations, and was successful.

Erichsen disposes of the subject of ligation of external iliac in a few words—gives no history of the operation, and only performed it once; the patient died of secondary hæmorrhage on the same day.

In regard to the obliteration of the iliac artery, certain facts were known at an early period of the last century. Gualtair and Scarpa's injections clearly established that although a ligature had been previously placed on the external iliac artery, the coloured fluid passed freely into the arteries of the thigh and leg.

Cases in which the external iliac may require to be ligated:—

1. Aneurysm of the femoral or popliteal artery.
2. Ilio-femoral aneurysm.
3. Wound of the artery (as in Velpeau's case).
4. Secondary hæmorrhage in compound fracture.
5. To facilitate the removal of tumours in groin,
6. And avoid sudden death from hæmorrhage.

Velpeau records a case of a young man, æt. 17, who inadvertently stabbed himself in the groin while cleaning a table, opening the external iliac artery transversely immediately above the epigastric. The artery was tied and the patient recovered.

The following are the principal dangers in performing ligation of the external iliac artery:—

- (1) Puncturing the peritoneum in the extra-peritoneal (Sir A. Cooper's method); (2) wounding the epigastric artery; (3) wounding the spermatic cord; (4) wound of circumflex iliac vein.

Chief dangers after operation:—

- (1) Secondary hæmorrhage (especially if the operation is done low down on the artery); (2) gangrene; (3) peritonitis.

TWO CASES OF LIGATURE OF THE LEFT CAROTID

FOR

ANEURYSM OF THE ARCH OF THE AORTA. (a)

By CHRISTOPHER HEATH, F.R.C.S.,
Consulting Surgeon to University College Hospital, &c.

THE following are the notes of the sixth and seventh cases in which I have tied the left carotid for aneurysm of the arch of the aorta.

Martha Fogarty, æt. 61, following the occupation of a monthly nurse, came under the observation of Dr. Robinson at the Mile End Infirmary in July, 1890.

(a) Read before Royal Medical and Chirurgical Society, February 11th, 1902.

Since her husband's death she had supported herself by monthly nursing and the letting of lodgings, and never undertook anything like hard work. Three years before she experienced pain in her right shoulder, which was shortly afterwards followed by the discovery of a pulsating swelling above the right clavicle. She thereupon went to the London Hospital and remained there three weeks. It was then proposed to perform some operation for her relief, but this she declined and took her discharge.

In December, 1889, when nursing a lying-in case, she noticed that the act of coughing caused her great pain in the supra-clavicular region, and about the same period her voice became cracked. Soon after Christmas of 1889 she could not lie comfortably on her back, and when she did so experienced a feeling of impending suffocation.

In July, 1890, she was admitted to the Mile End Infirmary, when Dr. Robinson noted a marked pulsation in the supra-sternal notch. She was kept closely in bed, and iodide of potassium was administered in full doses for many weeks, but no alteration in the pulsation resulted. She suffered a good deal from cough, and complained of constant pain in the neighbourhood of the pulsation, and this was much intensified during the act of coughing. Over the pulsation a marked bruit was audible, a similarly well-marked systolic bruit being heard at the apex-beat. The pulses in the wrists were equal in volume and regular, 92. There were no signs of arterial degeneration in the superficial vessels anywhere. Her invariable position in bed was a sitting one, with the knees drawn up and her head resting on them. On the slightest inclination backwards there was an increase of the dyspnoea, and inspiration was accompanied by stridor.

The patient was small and of spare build. Her hair was turning grey, and the arcus senilis was well marked. Her complexion was sallow. There was no local oedema. After the treatment by rest and the iodide had been pursued for some weeks without any improvement in the patient's condition, the advisability of submitting to an operation was placed before her by Dr. Robinson, and she consented to it. Accordingly Mr. Heath applied a carbolised silk ligature to the left carotid, above the omo-hyoid, on November 16th, 1890, no anæsthetic being employed. On the evening of the operation the temperature of the left side of the face was 82°, that of the right side being 94°. The pulse in the left radial was noticed to have diminished in volume considerably. The patient at this time complained of a throbbing pain in the neighbourhood of the incision, and also of dysphagia. The pain in her right shoulder she declared to be gone.

On November 19th (third day) it was noted that respiration, which had been distinctly noisy, particularly inspiration, was now unaccompanied by the least noise. The patient was much better, able to recline against her pillows and indulge in sleep, and declared herself quite comfortable. The pupils were noted to be equal and active.

On November 22nd she was able to sleep for seven hours, a thing she had long been a stranger to. The wound healed by first intention, and her progress was uneventful until January 3rd, 1891, when she complained of some return of the pain in the right shoulder and in the interscapular region. She had occasional attacks of epistaxis about this time without obvious cause, and some cough of a laryngeal character persisted. In February, 1891, the pulsating tumour above the sternum, though still visible, was thought to have contracted, and the patient was able to lie and sleep in any position without discomfort. On April 3rd (five months after the operation) she complained of some return of dysphagia. In June, as she complained of some recurrence of pain in the right shoulder, and the pulse was full and hard, Dr. Robinson ordered her tablets of nitroglycerine, under which the pain subsided. She continued to improve, and was discharged from the infirmary at her own request on August 8th, 1891.

This patient was admitted to the London Hospital under Dr. Gilbert-Smith on September 3rd, 1891, when a pulsating tumour existed at the inner edge of the

right clavicle, and could be just felt about it. About the middle of November she began to complain of great pain shooting through the sternum and between the shoulders, and died suddenly on November 29th, 1891, more than a year after the operation.

For the following abstract of a case of aneurysm under the care of Dr. Roberts, I am indebted to Mr. Bucknall, late Surgical Registrar of University College Hospital.

James Smith, *et. 36*, a labourer, was admitted November 4th, 1898, complaining of "pain in the chest." From boyhood till the age of twenty-six he served as a hand on a fishing-smack. Since then he has worked as a rough labourer, doing heavy lifting. For seventeen years he has served his time in the Militia Artillery, "lifting guns." Was in bed with rheumatism for seventeen weeks at the age of twenty-two. Had some swellings in the groins once, but no syphilis. Often drunk, and smoked half an ounce of shag daily.

Family History.—Father died of consumption, *et. 28*.

Present Illness.—Began in April, 1898, with pain behind the sternum, which came on when he ceased working, and lasted till he settled to work again, and "warmed to his work."

In September the pain became worse, and spread over the right upper chest to the scapula, and ran down the right arm as far as the internal condyle. He had to give up work and go to bed for four days. The pain continued to get worse, and was least felt whilst doing manual labour. During October, 1898, he had a cough.

State on Admission.—November 5th.—Patient presented all the signs of an aneurysm projecting forwards in the first and second right intercostal space. The first and second right spaces were bulged, and dull on percussion for a distance of one inch from the sternal margin, and pulsation of an expansile character could be seen and felt here, and in the episternal notch and right supraclavicular fossa. The inner ends of both clavicles were projected forwards by the swelling, especially the right, and each beat of the pulse threw them further forward, and caused a heaving of the upper part of the chest. Some dilated veins lay over the front of the chest, and the jugulars were also distended.

Patient had a frequent brassy cough, and the voice was harsh; but the laryngoscope showed that both cords moved equally. There was marked "tracheal tugging," the right pupil was larger than the left (slightly), and the right radial pulse might have been a shade earlier than the left; it was certainly much larger in volume. The pulse was regular, 68 to the minute, high tension, large, collapsing rapidly during diastole in a manner typical of aortic regurgitation. Heart apex-beat heaving in fifth space, in the nipple line.

On auscultation a blowing systolic murmur could be heard over the aneurysm; the second sound could be clearly heard in the second right interspace, and along the left border of the sternum a murmur could be heard following the second sound, and running through the whole period of diastole. A blowing systolic murmur could be heard at the apex. The lungs were examined, and found healthy.

Notes before Operation.—During November and December, 1898, and the first half of January, 1899, patient had severe attacks of pain in the shoulders, back, and side of the neck, and face. The aneurysm at first became smaller, but during January it increased in size, and definite swelling and pulsation appeared beneath the pectoral just below the right clavicle. During this period patient's temperature remained normal. On January 18th patient was transferred for operation.

Operation (January 18th, 1899).—The left common carotid was ligatured with carbolised silk opposite the cricoid, eucaïne *B* being used as a local anæsthetic. There were no succeeding nervous symptoms. On January 19th and 20th the patient slept badly, owing to pain in the region of the aneurysm. On the 20th the pulsation in the aneurysm was distinctly less marked, and daily improvement was noted until February 1st, when he returned to the medical ward with the operation wound healed. The pulsation was now much less distinct and forcible, and patient was free from pain and had slept well since January 20th. His cough was less

frequent, and less brassy in character. On February 16th patient complained of pain in the chest and cough, and on listening to the chest râles and rhonchi could be heard scattered over both lungs. On February 17th his temperature shot up to 103°, and from this date till the day of his death (March 21st) he had constant remittent fever varying between 100° and 104°, usually about 102°, with daily remissions of two to three degrees. The lungs showed all the signs of rapid and widespread tuberculous infiltration and consolidation, and later cavity formation at the apices was evident. The patient grew thinner and weaker daily, and expectorated copious purulent sputa containing tubercle bacilli. He sank and died on March 21st, having been ill a little over a month. The aneurysm gave rise to no symptoms during this time, and was daily less evident.

The post-mortem specimens from patients on whom I tied the left carotid for aortic aneurysm are four in number.

1. The patient was a labourer who had had a pulsating swelling in the neck for nearly a year, and was under the late Dr. Cockle when I tied his left carotid with catgut in February, 1872. "The symptoms due to the pressure of the aneurysm at once abated." When seen in March, 1873, he was in a very satisfactory condition, but in June, 1875, after resuming his laborious occupation of hedging and ditching, a pulsating tumour much larger than before the operation projected above the sternum. The aneurysm burst externally in September, 1876. (See "Clin. Soc. Trans.," vol. v., p. 183, and vol. x., p. 96.)

"The arch of the aorta is generally dilated; upon the anterior surface of its ascending portion is an oval opening, about an inch and a half in diameter, which communicates with a large sacculated aneurysm. The aneurysm projects forwards, and ascends in the neck beneath the sterno-hyoid and thyroid muscles as high as the cricoid cartilage, where there is a large opening, at which it had burst through the skin. The transverse portion of the arch is compressed by the sac, and the left brachio-cephalic vein is obliterated. The posterior surface of the sternum is eroded and forms part of the wall of the aneurysm, which had also compressed the left lung. The left carotid artery is obliterated and contracted at a point half-an-inch below the cricoid cartilage, where a ligature has been applied; it contains a fibrinous coagulum only adherent at the seat of ligature. There is no evidence that the internal coats of the artery were divided by the ligature" (College of Surgeons Museum, 3167).

With regard to this last statement, I may mention that the catgut broke in tying, and that I then doubled it and tied the artery as firmly as I dared. The drawing given by Messrs. Ballance and Edmunds ("Ligation in Continuity," p. 193) of this preparation is in my opinion incorrect. It will be noticed that the sac contains no clot, for the reason that the examination took place three days after death in very hot weather, and in the country, and the decomposed condition of the clot necessitated the washing of it away. This was most unfortunate, as it has led to the idea that no coagulum had formed as a result of the operation, whereas a large amount of clot had formed, and had led to the apparent cure of the aneurysm until the patient resumed his labour, when it again grew and burst externally, four and a half years after the ligature was applied.

Specimen 2, from a man, æt. 38, whose case is reported in the Clinical Society's "Transactions" for 1891, by Dr. H. E. Harris, under whose care the patient was in the St. George's-in-the-East Infirmary. I tied the left carotid on March 8th, 1890. For a fortnight the aneurysm appeared to decrease in size, but the patient was more distressed with dyspnoea and cough. After that date it again increased in every direction and became more prominent, and the patient died suddenly on May 12th, two months after the operation.

The aneurysm springs from the upper and anterior part of the transverse portion of the arch, with which the sac communicated by a rounded opening of 1½ inch diameter. The opening is entirely to the proximal side of the great vessels, and the sac projects upwards and to

the left, its summit being 1½ inch above the sternal notch. The sac is entirely filled with clot, of which the outer layer, from three-quarters to one inch in thickness, is composed of decolourised fibrin, while the central portion is made up of ordinary red coagulum. From the orifice of the aneurysm ante-mortem clots extend in a radiate fashion into the aorta, and into the innominate and left subclavian arteries, in which they tail off to threads. This clot, after being subjected to the action of weak spirit, was smooth, well-defined, of considerable consistence, and separated like a membrane from the body of the clot. A section of the main clot showed it to be fleshy, and slight pressure caused it to split up into laminae. Just above the aortic opening the clot was distinctly adherent over a surface nearly an inch in length to the concavity of the arch, which was extensively calcareous.

A ligature had been applied to the left carotid five-eighths of an inch below the bifurcation of the artery, at which point the vessel is interrupted for about half-an-inch by a mass of fibrous tissue. Above, the artery is completely filled by an organised but still coloured clot. Below, a completely decolourised clot extends along and is firmly adherent to the posterior wall of the vessel; this clot ceases 1½ inch above the commencement of the artery, with the exception of an exceedingly fine filament, which is continuous with the clot in the aneurysm. The remains of a ligature may be observed embedded in the fibrous tissue, which has also entangled the pneumogastric nerve (College of Surgeons Museum, 3167A).

Specimen 3 was from Dr. Robinson's patient.

The first part of the arch of the aorta is uniformly dilated. From the right superior aspect of the transverse arch, in front of the innominate artery, which is dilated and involved, springs an aneurysmal sac of the size of a small orange, with an opening into the aorta of the size of half-a-crown. The sac was adherent to the trachea, and is almost completely filled with laminated clot. The left carotid is filled with firm adherent clot, and higher up is obliterated by a ligature, which has disappeared. The clot in the left carotid does not extend into the aorta. The aorta was extensively diseased (University College Museum, 1233).

Specimen 4 was from Dr. Roberts's patient. There are two aneurysmal sacs, a large one springing from the ascending aorta, and a smaller one arising from the back of the innominate artery. Both contained laminated clot. The aortic aneurysm forms a tumour as large as a clenched male fist, lying to the right of the extra-pericardial ascending aorta, and communicating with its lumen by an orifice the size of a florin. This pierced the antero-external wall of the vessel about midway between the pericardium and the origin of the innominate. The fibrous tissue forming the wall of the aneurysm extended around the vena cava and the origin of the innominate, and to the jugular vein. The manubrium sterni and ribs are adherent to the sac. On opening the aneurysmal sac it was found to be filled with clot, the central part soft and rather fluid, the main mass distinctly laminated. The most peripheral portion was decolourised.

The innominate aneurysm forms a tumour as large as a hen's egg arising from the artery a quarter of an inch from its bifurcation. It lay behind and to the left of the larger aneurysm, to which it adhered, being in close contact with, and adherent to, the trachea on the inner side. It contained laminated clot, and communicated with the larger sac by its lower end. The left carotid is obliterated an inch below the bifurcation and converted into a fibrous cord half-an-inch long. Below that there is solid clot filling the vessel to within half-an-inch of the aorta close to the larger sac. The aorta is extensively diseased. The lungs were universally adherent and solid with tubercles, which had broken down beneath the apex of both upper lobes, leaving a ragged cavity the size of a small hen's egg in each (University College Museum, 1234).

That the application of a ligature to the left carotid has an effect upon an aneurysm of the transverse portion of the arch of the aorta is, I think, sufficiently shown by the cases just read. In the woman it is

noted that on the third day after the operation the respiration, which had been distinctly noisy, had become quiet, and the patient was able to recline against her pillows. On the sixth day she was able to sleep for seven hours consecutively. In the man on the third day the pulsation of the aneurysm was distinctly less marked. But the relief in my first case (Dr. Cockle's patient) was most marked, for I brought him before the Clinical Society more than a year after the operation, when it was recorded that "the patient is in perfect health, and feels no inconvenience from his chest. He sleeps well, and can lie on either side equally well. The right chest wall in front is quite restored to its natural shape, or if anything is a little flatter now than its fellow. On palpation, the heaving impulse formerly existing over the right anterior chest wall is almost entirely gone. On percussion, the right anterior chest wall, formerly so dull, has, to a considerable extent, recovered its normal condition." (Clin. Soc. "Trans.," vol. vi. 1873).

The preparation from this patient shows no clot, for the reason I have already given, but the other three preparations show thick laminated clot in each sac, and in the last case (Dr. Roberts's) the second or innominate aneurysm was also full of clot.

Various theories have been advanced to account for the formation of laminated clot in these cases. The simplest was that it depended upon the enforced rest in bed following the operation; but the fact is that in every case the effect of prolonged rest in bed had been tried for many weeks without the slightest benefit. Next it was suggested that the clot, beginning at the point of ligature, spread down into the aneurysm, and thus led to the formation of a coagulum in the sac. This is contrary to fact, as shown in the preparations before you, for in no single case was the left carotid involved in the sac, and it is noted that the small thread-like clot, which, in some instances, spread down the carotid, in one case only extended into the aorta, and joined that in the aneurysm. I maintain the view which I have always held about these cases, viz., that the distal ligature affects the current of blood in the aneurysm, probably by retarding it, and thus causes it to flow around the sac instead of directly through or past it, and in this way leads to the deposit of laminated fibrin on the probably roughened wall of the sac.

When this normal cure of the aneurysm has gone on for some time, there is no doubt a tendency for the small remaining cavity to become blocked with soft coagulum, and this is probably a critical moment for the patient, and may account for the sudden deaths which have occurred at considerable periods after the operation. An aneurysm which is semi- or completely solid must necessarily exercise much greater pressure on its surroundings than one which only contains fluid blood, whilst the sudden arrest of a stream of blood through a sac so near the heart would be likely to interfere with its action and lead to syncope.

THE INFLUENCE OF SOME OF THE COMMONER DRUGS UPON THE GASTRIC FUNCTIONS. (a)

By BOARDMAN REED, M.D.,
Of Philadelphia.

THE following observations were made in my laboratory on five persons employed in an office building in Philadelphia during February, March and April, 1901. None of them complained of their stomachs. They were not invalids or under medical treatment, though some of them realised that they were not in robust health. In every case the stomach contents were extracted by a Kuttner rubber bulb, one hour after an Ewald test breakfast, with one exception, when the time was fifty minutes. The con-

tents were filtered before being examined. No attempt was made to empty the stomach completely, since to do this adds needlessly to the discomfort of the procedure and does not add any important reliable information. The motor power of the stomach can be measured much more accurately and conveniently by other means. All the persons thus experimented upon had been eating ordinary diet, and were directed to continue with the same food and under like conditions otherwise during each period of observation.

It is first of all noteworthy, that of these five average persons, all engaged actively in earning a livelihood and none of them complaining of any stomach symptoms, only two, Cases 1 and 2, had an approximately normal gastric secretion and peptonising power. Case 4 showed some sourness from fermentation and far too low a figure for the combined HCl, which is a fairly accurate measure of peptonisation. Other tests pointed to deficient motility in this case. The total acidity percentage of HCl was, however, about normal. The two others had less than the normal amount of HCl; indeed, a marked deficiency of it.

The tincture of nux vomica was chosen for the first test, since it is one of the most active and bitter, as well as one of the most commonly administered, of all our so-called stomachic and general tonics. The results might at first be considered rather contradictory, since in two cases the use of the remedy before meals for five days produced a lessened secretion, while in the other three there was a decided increase. This outcome is especially interesting for the reason that the depressing effect took place in the two persons whose gastric juice was practically normal, persons, therefore, who did not need medicine for their stomachs; and the stimulating effect occurred in the three who exhibited manifest gastric faults, one of them a somewhat impaired motor power, and the two others a marked lack of HCl. Five cases are too few of course, to warrant any sweeping inferences, but there has been an abundance of clinical observations which show that any organ which is functioning healthfully already, is likely to be injured by drug stimulation.

The next test, to ascertain the effect on the gastric glands of administering HCl regularly for a time, yielded remarkably striking results, which being in complete harmony with clinical observations reported of late from various parts of the world, must be accepted as conclusive.

Every one of the five persons who took 10-drop doses of dilute HCl in water after meals for a period of five to six days, experienced a very positive stimulant action upon the glands whose function it is to secrete HCl, and the two virtually normal stomachs whose glandular apparatus was depressed by the nux vomica, not only regained what had thus been lost, but had their secretion carried to a higher level than before; higher, indeed, than normal. In one of these the HCl reached a point which may be considered hyperchlorhydria. And this resulted in the short period of five days from doses of dilute HCl, which many writers regard as altogether too small to be effective.

But the mistake has frequently been made of overlooking the exceedingly important fact, that this remedy, besides its occasional palliative action when given in very large doses, by aiding a deficient gastric juice directly in the work of peptonising proteids in the stomach, in the presence of a sufficient amount of pepsin or propepsin, possesses also the property of exerting positive stimulant action upon the glands by which HCl is secreted.

It is generally conceded that the administration of HCl as a medicine tends gradually to increase the secretion of the same acid by the stomach. In some

(a) Abstract of paper read at the Annual Meeting of the American Medical Association.

of my cases in which there was an almost entire absence of such secretion, the administration of dilute HCl in doses of five to ten minims after meals for long periods, as three to six months continuously, has been followed at last by a restoration of the secretion to the normal amount. The fact that small doses of HCl, in conjunction with other appropriate treatment, may produce this restorative effect in many cases—probably in most cases in which atrophy of the glands has not developed—may be considered as fully established. It has been also proved that even small doses of HCl may set up hyperchlorhydria in normal stomachs, or aggravate it when that condition already exists.

Three of the persons experimented upon took five grains of scale pepsin for periods of from seven to seventeen days, their stomachs being least normal. These tests of pepsin were made about a month after finishing with the other ones, though in one case the person finding HCl so beneficial, had taken a dose or two nearly every day during the interval, and another had taken it with an approach to regularity during the same time. One had taken no HCl for fully three weeks when she began the use of the pepsin after meals. None of the three took any HCl during the experiment with pepsin. Without these explanations one might infer, from the results shown in the tables above, that an active preparation of pepsin, so far from exerting any restorative influence, tends to produce a lowering effect upon the gastric secretion, and possibly it may in some cases. But it will be noticed that in the trial upon the person who took no HCl for several weeks before the pepsin test, there was virtually no change in the amount of the HCl secretion and digestive work done before and just after the week during which pepsin was administered. In the other two cases the falling off in the secretion of HCl and in digestive work during the period that pepsin was administered and HCl not administered, may, therefore, no doubt, be properly attributed to the withdrawal of the acid, which we now know to be our most active gastric stimulant.

It is a fair inference from these experiments that pepsin given as a digestant, though known from a large number of clinical observations to be a helpful palliative under certain conditions, does not, at least, like numerous other glandular products of the body, tend to augment the natural secretion of the same by its prolonged use.

An additional series of experiments was carried out in April, 1901. In each of five different persons, three of whom had a deficient secretion of HCl at the time, the following experiments were made, and in the case of one of them the same were repeated a week later: Small cubes of coagulated egg albumen of the same size were prepared and one of these introduced into each of four test tubes with 3 c.c. of the filtered stomach contents taken up one hour after an Ewald breakfast. Nothing further was put into tube 1; to tube 2 two grains of scale pepsin were added; to tube 3 one drop of dilute HCl, and to tube 4 both pepsin and HCl were added. All the tubes were then placed in an incubator and the temperature kept as nearly as possible at 38° C. The results of these tests need not be reported here in detail, yet a summary of them may be instructive.

In two only of the six tubes to which pepsin was added was there shown any more rapid solution of the egg than where the chyme alone was allowed to act. The analysis in one of these two cases previously made had shown somewhat more than the normal proportion of HCl—free HCl, .094; combined, .080—and the other revealed a marked deficiency.

In the other five experiments, while in every case except one there was free HCl present though deficient in amount, there resulted a distinct retarda-

tion of the digestive process in all the tubes in which pepsin alone was added to the mixture of chyme and egg.

The addition of HCl alone produced a doubtful result in one case, *i.e.*, there was no appreciable difference between the amount of digestion in the tube with only the stomach contents and that in which HCl was added. In three of the cases it helped more or less, though in one only slightly. In the case of one person with whose chyme the test was made twice at an interval of one week, the result was each time a positive retardation of the digestive process. The analysis of a portion of the same chyme showed the first time T.A. 50, with free HCl .065, and the second time T.A. 46 and free HCl .065, combined HCl .058—certainly not an excess of secretion.

The addition of both the HCl and scale pepsin produced a more rapid solution of the egg in each of the six trials. Test-tube experiments in digestion have, of course much less value than when the remedies are administered to living persons. Many of us have been led to consider pepsin especially a very mild and safe remedy, which is not likely to do harm even if it can do no good. Acting on this principle, I recently prescribed moderate doses of pepsin for a very delicate lady who would not permit a test of her stomach contents to be made, and the result was a severe aggravation of her symptoms. She then informed me that she had once before experienced a similar result from the same medicine.

The increased digestive power exhibited by all the six specimens of stomach contents when pepsin and HCl were both added, even in persons the action of whose gastric juice was notably retarded by either drug alone, is curious and most interesting. It shows the folly of dogmatizing too positively as to just what part any particular element of a secretion plays in the observed effect, and the wisdom of humbly endeavouring to imitate Nature as nearly as possible in concocting remedies to supply a deficiency in the work of any organ. It is very likely that if we should combine pepsine, HCl and rennin with water and other minor ingredients of the gastric juice in the proportions usually found in the human stomach, we should obtain a remedy of much greater effectiveness than any now in use for weak digestion.

The results of the foregoing experiments would seem to point toward the following conclusions:—

1. Perfectly normal stomachs are probably in the minority in large cities, especially among persons employed indoors.
2. In stomachs which are normal or approximately so, the digestion may be injured by a simple bitter tonic, taken even for a short time.
3. Quite moderate doses of HCl administered as a medicine may prove effective in hypochlorhydria, but are likely to do harm to normal stomachs and certain to aggravate hyperchlorhydria.
4. Pepsin rarely produces any good result when given alone, even to persons with weak digestive power, and often then retards the digestion of albuminoids.
5. Pepsin and HCl given together much more frequently do good than either administered singly.

An Anti-Vaccinationist Guardian to Resign.

The Birmingham Board of Guardians have, by formal resolution, called upon one of their number to resign in consequence of the support given by that member to persons who had been summoned for non-compliance with the law. It is obviously absurd that a member of the very body which is entrusted with the task of carrying out the law should lend his personal support to endeavours to stultify that law, and the action of the Birmingham Board of Guardians has our hearty approval.

Clinical Records.

TUMOUR OF THE SUPERIOR MAXILLA.

By CHAS. F. FORSHAW, L.D.S.,

Hon. Dental Surgeon to the Bradford Boys' Orphanage, the Deaf and Dumb Institution, and the Women's Home and Shelter; Member of the Royal Society, Dublin.

Miss B. D., *et. 27*, a lady of healthy appearance, came to me some twelve months ago to ask my advice as to what should be done with respect to a swelling on the left upper jaw, which was about the size of a pigeon's egg, and which first made its appearance some twelve months prior to her visit to me. The tumour gave to the face an ugly asymmetry. Its situation upon the jaw was eight lines from the alveolar margin. It was slightly lobulated, sessile, and gave to the finger a sense of slight pulsation. Its origin could not be directly traced to the periodontal membrane lining the alveolus in connection with any decayed teeth. In general appearance the enlargement suggested gumma, epulis of an unusual form, or epithelioma. She had been treated with pot. iodid. without benefit, and there was no history or symptoms pointing to a specific origin. There were no glandular enlargements at the angle of the jaw or about the triangles of the neck. The growth appeared to spring from the labial surface of the alveolar process. Its growth had been very rapid for the last three months, and was quite unaccompanied by any form of ulceration, nor was there any pain.

Miss D. had worn a partial upper vulcanite denture for some years, which was displaced so much as to show some of the natural teeth in both the superior and inferior maxilla, owing to her being unable to quite close the mouth on account of the protuberance of the tumour. In January of last year the patient having been prepared, chloroform was administered by means of Junkers' inhaler, Mason's gag was inserted in the mouth, the cheek retracted, and everything in absolute readiness. Mr. L., F.R.C.S., with my assistance, removed the growth with one sweep of the knife. The hemorrhage was very free; one or two vessels were picked up by catch forceps and tied. The actual cautery (the circular flat button) was now freely applied to the base of the ulcer so produced. This process was pushed so as to destroy the tissues right down to the bone, some of which was gouged away and removed. The wound was plugged with iodoform gauze, and the patient allowed to recover from the anæsthetic, after having been under its influence less than a quarter of an hour. The total quantity of chloroform used was one drachm. In seven days the lady's face had resumed its normal appearance. She was much brighter and had even increased her weight. We also, at the same time, excised the edge of the scar, where the alveolar process adjoined the buccal mucous membrane, which had a slightly suspicious feel of rigidity, the portion removed being about three-quarters of an inch by an eighth of an inch in breadth. I saw her again the following week, and on this occasion the healed surfaces had quite a healthy appearance. There has been no return of the condition up to the present time, March 21st, 1902, when I last saw her. On examination, the tissue removed in the recent state had a fibrous appearance, containing numerous vessels, some of which were of large size. It presented, microscopically, many thin-walled blood channels, lying in a stroma, of small spindle-shaped cells, among which could be discovered a few of a myeloid type, certainly suggestive of mild sarcomatous malignancy.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, APRIL 11TH, 1902.

MR. HOWARD MARSH, F.R.C.S., President, in the Chair.

CASES ILLUSTRATING THE MODE OF ORIGIN OF CERTAIN CYSTS OF THE NECK.

MR. T. CARWARDINE (of Bristol) read a paper in illus-

tration of the mode of origin of certain cysts of the neck. Cysts and fistulæ arising from the thyro-glossal duct, he observed, usually had a pedicle which passed through the thyro-hyoid membrane in the middle line, below the hyoid bone, between the body and the thyroid cartilage. These, he suggested, might be termed thyro-hyoid cysts. He related the case of a man, *et. 31*, deaf and dumb and one of twins, with a fluctuating, superficial median tumour of the neck, overlapping the episternal notch and manubrium sterni, and a hard cord could be traced upwards from it, in front of the cricoid cartilage. The pedicle was found to pass through an interval in the cervical fascia into the middle of the crico-thyroid membrane. It was evidently what he would call a crico-thyroid cyst. Two years later he met with a similar and homologous cyst in the space between the lower jaw and the hyoid bone in a lad, *et. 12*, who had noticed a lump in his throat for six months. The diagnosis of hyo-mandibular cyst proved to be correct at the operation. There were thus three median cysts—hyo-mandibular, associated with the first cleft; thyro-hyoid, associated with the second cleft; and crico-thyroid in the succeeding cleft. He related a case of cystic hygroma in a baby a few weeks old, in which the cyst, like a ranula, projected under the tongue. He described the anatomical relations of the cyst, observing that the cyst appeared to have originated in a lateral diverticulum of the first, or hyo-mandibular, cleft, though, in a similar case of Treves', the origin appeared to be from the second branchial cleft. He also referred to a tumour below the left angle of the lower jaw in a young man, which proved to be a chondro-adenoma, also a dermoid cyst of the whole of the first branchial cleft (*Bristol Medical Chirurgical Journal*). His last case was that of a man, *et. 33*, who had had a swelling on the right side of the throat for two years, which he took to have for origin a diverticulum of the sinus pyriformis, *i.e.*, from the third or fourth visceral cleft. He discussed the classification of these cysts according to their origin, into median and lateral, corresponding to the visceral clefts, and alternating with the visceral arches.

MR. BOWLBY described a cyst of the neck of an epitheliomatous nature. He asked if the author had met with any such, also if he had met with any difficulty in treating fistulæ resulting from operation in these cases.

MR. BARKER suggested that cysts of the neck were sometimes of the nature of lymphatic navi.

DR. ST. CLAIR THOMSON and MR. STANLEY BOYD described cases of the kind.

MR. CARWARDINE, in reply, said he had met with great difficulty as regards fistulæ. He had not gone fully into the question of epitheliomatous cysts. He was not prepared to deny the possibility of the existence of cysts like those described by Mr. Barker.

INTESTINAL OBSTRUCTION DUE TO EMBOLUS OF A BRANCH OF THE SUPERIOR MESENTERIC ARTERY.

MR. W. J. TYSON related the case of a woman, *et. 66*, who came complaining of slight pain over the liver, sickness, constipation and some epigastric tenderness, her temperature being normal. The symptoms gradually became worse, and ultimately the vomit became "coffee-ground." Laparotomy was done and the small intestine was found to be slightly congested and adherent in the right fossa, where about a foot of gangrenous bowel, greatly thickened, was seen. The affected part, which was obviously due to thrombosis, was freely excised and the end united with a Murphy's button. She died thirty-six hours after the operation, and, post-mortem, atheromatous erosion of the descending aorta was found, with blocking of a branch of the superior mesenteric artery. He discussed the symptomatology of this condition, remarking that the symptoms were at first those of ordinary colic with a gradual change in the vomit. Constipation was the rule, but diarrhœa was often present, and, later, tympanites. The prognosis was always grave but not absolutely fatal.

MR. LUNN described a case of a somewhat similar nature.

THE PRESIDENT cited the case of a gentleman thrown from his horse on to a heap of stones, alighting on his

abdomen. No symptom of any gravity occurred for a few days, when he developed symptoms of acute obstruction. Operation revealed gangrenous gut, and post-mortem thrombosis of the superior mesenteric artery was found.

Mr. BOWLEY mentioned a case of gangrene of the fingers, thought to be due to frost bite. Patient shortly after developed acute abdominal symptoms and soon died. Post-mortem revealed general condition of embolism in the mesenteric area.

CEREBELLAR ABSCESS WITH SUDDEN PARALYSIS OF THE RESPIRATORY CENTRE.

Mr. A. E. BARKER related the case of a girl, *et. 14*, who, three months before admission, had had scarlet fever with otitis media. A fortnight before admission she complained of earache followed by great weakness and vomiting, and rigors. The limbs were flexed and the head retracted, with dulled intelligence. There was profuse foetid discharge from the ear but no swelling over the mastoid. Pupils and discs normal. He diagnosed intra-cranial abscess with thrombosis of the lateral sinus and deep jugular vein. It was decided to operate, but when the patient was lifted to be taken into the theatre respiration ceased, and in spite of artificial respiration and the inhalation of oxygen there was no sign of normal respiration though the heart continued to beat strongly. Artificial respiration was kept up for an hour, when, as normal respiration did not return, he made a small incision through the skull into the temporo-sphenoidal lobe. No pus was found, but on passing the needle into the lateral ventricle a large quantity of almost clear fluid was evacuated. He then opened over the lateral front of the cerebellum, and after a few punctures reached foul gas and pus anteriorly. This, however, had no effect on the respiration or heart. Artificial respiration was kept up for another hour, but the patient was obviously dead, though the heart continued to beat as before for two hours and thirty-five minutes after natural breathing had ceased. Post-mortem, a large cerebellar abscess was found in the usual situation, which had been partially emptied by the operation.

Sir DYCE DUCKWORTH related a similar experience of his own of failure of respiration prior to cardiac failure, an occurrence to which he had directed attention in his paper read at the International Medical Congress at Moscow.

Mr. H. L. BARNARD ON

THE SIMULATION OF ACUTE PERITONITIS BY PLEURO-PNEUMONIC DISEASES.

Andral appears to have recognised this condition clearly in 1836, and narrates several typical cases. Watson quotes him, and Fagge gives one case. Modern writers for the most part are vague in their description, and do not include peritonitis in the differential diagnosis of pleurisy or *vice versa*. The thoracic conditions which have given rise to these abdominal signs in the writers' cases were always basal in lung or pleura. (1) Two cases of pleuro-pneumonia. (2) Two cases of pyo-pneumothorax apparently originating in the apex of the lower lobe. (3) One case of traumatic pleurisy, with fracture of the left lower ribs. The abdominal signs and symptoms which result may be divided conveniently into (a) parietal and (b) visceral. (a) Parietal. The abdominal wall is acutely tender and painful. This tenderness may be general or one-sided, and is frequently more marked below in the right or left iliac region (10-12 D areas) so as to simulate appendicitis. The muscles are in spasm, so that the belly is bound like a hand. The deepest anaesthesia is necessary to relax this spasm. Respiration is of the costal type. (b) Visceral. The patient frequently suffers from nausea, hiccup and vomiting, which may be urgent and bilious. The intestines become distended. Constipation is usually present, and enemas may be retained. In some cases the onset is sudden with collapse like perforative peritonitis. The diagnosis is easy if once suspicion is aroused. The chief points are the rapid respiration (40 and up), the slow good pulse (under 100), the absence of the abdominal facies especially of rings round the eyes, and the fact that the abdominal wall

softens momentarily at each respiration. Direct signs of the thoracic condition are often wanting for twenty-four hours. The pathology is one of referred pain, and divides itself into three heads: 1. Irritation in continuity of the lower six dorsal nerves will explain abdominal hyperaesthesia and spasm. 2. Referred visceral pain (Henry Head) will explain the abdominal and head pain of an early pneumonia not involving the pleura. Visceral impulses pass into the root ganglia of 7, 8, and 9 D, and exalt their excitability as that impulses from the skin to those ganglia become painful. Reflex spasm follows in the distribution of the nerves. 3. The visceral signs must be explained either by some reversal of this reflex or by direct involvement of the splanchnic nerves (from 6-12 D) above or in the diaphragm.

Sir DYCE DUCKWORTH said that if these cases were properly examined on admission mistakes of this nature would not occur.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SURGICAL SECTION.

MEETING HELD AT THE ROYAL COLLEGE OF SURGEONS ON FRIDAY, APRIL 4TH, 1902.

Mr. THOMAS MYLES, President of the Section, in the Chair.

Mr. KENNEDY exhibited the vermiform appendix of a baby five months old, removed from the right inguinal canal during the operation for the radical cure of hernia. Mr. Kennedy also exhibited a patient, five months old, on whom he had performed the radical cure operation for hernia on the right and left inguinal canals, excised the appendix, and performed circumcision.

Mr. ALEXANDER BLATNEY exhibited a girl on whom he had operated two months previously for a perforated gastric ulcer. The operation was performed nineteen hours after the rupture. The opening was found near the lower curvature of the stomach, on the anterior wall close to the oesophagus. The patient made a good recovery, but a week afterwards the temperature rose, and on opening the wound a large abscess was found under the left wing of the diaphragm. This was drained by an incision between two of the lower ribs; the original wound was closed, and the patient made a complete though somewhat tedious recovery.

Mr. HENRY G. CROLY read his paper

ON LIGATION OF THE EXTERNAL ILIAC ARTERY FOR ILIO-FEMORAL ANEURYSM AND OTHER TUMOURS.

Mr. H. G. Croly commenced by giving a *resumé* of the anatomy of the artery, especially its relation to its vein on the right side, and the presence of the fibrous septum that separates the vessels, and exhibited some beautifully-coloured illustrations painted from nature by Dr. Paul Carton. His incision was planned to allow of the artery being tied at least one inch and a-half from the origin of the deep epigastric artery. It commenced on a level with the umbilicus, and curved downwards, outwards, and inwards, ending at a point midway between the symphysis pubis and the anterior superior crest of the ilium. By making the incision superficial he avoided bleeding. The ligature used was ox-peritoneum or gold-beater's skin, as recommended by Lord Lister, and described by Messrs. Ballance and Edmunds. He tied the ligatures in the "stay-knot" of Ballance, which he considers the most secure of ligation knots, and the one least likely to tear the inner coat of the vessel, which should never be allowed to occur. The arterial wall was healthy, and the patient, who was exhibited, made a good recovery from the operation, which was an extra peritoneal one. A series of casts and photographs showing the aneurysm before operation, a few days after operation, and when the patient was convalescent, were exhibited. The paper will be found in *extenso* on page 397.

The PRESIDENT (Mr. Myles) had listened with much pleasure to Mr. H. G. Croly's very interesting paper; interesting both from its anatomical and clinical aspects. He quite agreed with Mr. Croly in selecting a site some distance from the deep epigastric artery for ligation;

but he was not so sure that the secondary hæmorrhages which were so common in the past were due to the site of ligation. The *locus in quo* did not account for everything. The good result was no doubt partly due to the better site of ligation chosen by Mr. Croly; but there was something more—to-day we had aseptic methods, aseptic ligatures, aseptic handling of the wound. He would like to hear from Mr. Croly how he prepared the ligatures; also if he found the pulse of the posterior tibial in the limb operated on soon after the ligation. When we think of the care taken by surgeons to-day to ensure aseptic conditions, and recall the methods of the past, we can only ascribe the successes of the older surgeons to the providential mercy of God.

The VICE-PRESIDENT (Mr. L. H. Ormsby) felt that they should all be very much obliged to Mr. Croly, one of their senior surgeons, for taking the trouble of coming there and describing to them his operation. He had never had an opportunity of tying the external or common iliac artery; but if he should be called on to perform such an operation he would adopt Mr. Croly's methods and be well satisfied if he obtained equally good results.

Mr. LANE JOYNT by the reference to the old surgeons and their methods was reminded of a painting he saw not long since on the wall of a house in Pompeii, which represented a surgeon in the act of cutting down on the femoral artery in Hunter's canal. The line of incision was that followed by Hunter.

The HON. SECRETARY of the Section (Mr. Lentaigne) thought that perhaps the older surgeons were too much blamed. He looked on secondary hæmorrhages as the result of sepsis; sepsis by silk ligatures and ligatures of other absorbent material, they retain septic matter in close union with the arterial wall, which soon becomes infected. All this was carefully avoided to-day with the excellent and brilliant results which they had just heard from Mr. Croly, to whom he offered his congratulations for the good results of his operation and for his valuable paper.

Mr. CROLY begged to thank them for the reception they had given his paper. He prepared his ligatures by leaving them for twenty-four hours in ether and then placing them in a solution of carbolic acid in water, of a one in twenty strength. He looked upon the fear of wounding the peritoneum as the reason the older surgeons tied the external iliac so near its distal end. This fear paralysed their action in cases of wounds of the deep epigastric and internal iliac arteries—they looked on wounds of the peritoneum as necessarily fatal, and rather than open it they left patients to die of internal hæmorrhage. He cut no muscular tissue by his incision; on coming down to the muscle tissue he pushed the transversalis fibres aside with his fingers and readily exposed the artery. He failed to find the posterior tibial pulse either after the operation or since, though, as was seen, the man makes no complaint of any lack of circulation in the limb.

Owing to the lateness of the hour Mr. Lane Joynt's paper was postponed, and the meeting terminated.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, April 13th, 1902.

DIPHTHERIA.

M. LEVESTRE read a paper at the Académie de Médecine on the Prophylaxis of Diphtheria by Injections of Lemon. Preventive injections of anti-diphtheritic serum produced immunisation in children exposed to contract diphtheria without giving rise to any serious accident. Although the immunisation was only ephemeral—three or four weeks—those injections were indicated in families where a case of diphtheria had developed to preserve the other children from contagion. However, when those children have been [separated from the contaminated dwelling, and were under medical supervision, the inoculations might be dispensed with.

Preventive injections were also indicated in children belonging to an agglomeration (schools, hospitals) in which cases of diphtheria had been observed.

Even in the absence of any diphtheria those injections might be indicated under certain special conditions (measles, scarlatina, &c.). However, in the case of measles, the preventive action appearing to be less certain, the doses of serum should be stronger and more frequently repeated.

ANEURYSM OF THE AORTA.

At the meeting of the Société de Chirurgie M. Tuffier related an interesting case of operation for aneurysm of the transverse portion of the aorta. It was that of a woman of 40 without syphilitic antecedents, who was sent to the hospital for a small tumour protruding in the second intercostal space on the right side. The speaker, finding that the tumour was pulsatile, pronounced it a case of aneurysm of the transverse portion of the aorta. His colleague who examined the patient thought that the lesion was localised to the limit of the ascending portion of the aorta without any general mischief to the artery. The radiograph showed that the tumour was situated on the lateral portion of the aorta. They were led to believe that the aneurysm was saciform, communicating with the aorta by a narrow orifice.

The development of the tumour having made rapid strides, and threatening to burst externally, he was constrained, in spite of the gravity of the case, to attempt a surgical operation. The dissection of the aneurysm was relatively easy, although there existed intimate adherences with the pleura. Having pressed the contents of the sac into the aorta, he placed a ligature on the orifice, tightening it very gently; after which he placed a second, but as he had not great confidence in the ligatures, he did not resect the sac. He believed he was wrong in not doing so.

All went on well until the twelfth day, when the temperature rose; the wound was exposed and gangrene was discovered in the sac. The patient died five days afterwards from secondary hæmorrhage due to the gangrene. He believed that if he had resected the sac that accident might have been avoided.

M. Delorme said that some years ago he studied the question of a possible surgical treatment of aneurysm of the aorta, and had come to the conclusion that a radical cure might be tried with some chance of success. But since that time the treatment of aneurysm with gelatine had given such good results that he did not think himself authorised to operate on aneurysm of the aorta.

CHILBLAINS.

Dr. Courtin, hospital surgeon at Bordeaux, employs with constant success oxygen water in the treatment of chilblains, ulcerated or otherwise.

In young children he reduces the oxygen water, which is always at twelve volumes, to three volumes, by adding hot boiled water. The hands or feet affected are plunged into this bath every day for half an hour.

For older children and adults the strength of the bath given is six volumes. In any case of the patient's present ulcerations, a saturated solution of borate of soda is added to the oxygen water in order to reduce the acidity and diminish the pain from the application.

The feet and hands blued by the chilblains become red after a few moments of immersion, the sores com-

mence to granulate after two or three days and heal rapidly. After the bath the sores are dressed with gauze and antiseptic vaseline.

Three baths of half-an-hour each suffice to cure ordinary chilblains. A large number is necessary in the case of ulceration.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, April 12th, 1902.

At the Hufeland Society Hr. Hausmann discussed the subject of the

CURABILITY OF PHTHISIS.

He made a distinction between pulmonary phthisis and pulmonary tuberculosis. There were quite a number of cases of phthisis in which tubercle bacilli were never found. In chronic bronchiectasis and in fibroid phthisis to which inhalation diseases belonged tubercle bacilli were absent. It was the same with tuberculous and reticular lymphangitis. In pneumonia in rare cases there arose an ulcerous phthisis, which was more frequent in recent years, perhaps under the influence of influenza. Further, syphilitic phthisis which was readily complicated by tubercle, had been for long denied. Finally, there was actinomycotic phthisis with peculiar widespread infiltrations, which in certain spots passed on to suppuration; fungi readily developing in the increased connective tissues.

These cases, which on the whole, especially when the disease was extensive, were very curable, with the exception of syphilitic phthisis—the speaker excluded from discussion, dealing only with tuberculous phthisis.

Recovery from this condition depended simply on the anatomical changes that had taken place; the bacteriological changes did not come into play. Typhoid and fibrinous pneumonias were curable in a marked manner. The changes that had taken place as the result of the disease were recovered from after the cessation of the disease. Pulmonary phthisis must be considered separately. This was not a simple disease, but a group of different diseases which were intermingled.

The ordinary form of pulmonary phthisis began almost invariably in the apices. The apices were free only under exceptional circumstances. In diabetes, which led to pulmonary phthisis, one also saw the process commence occasionally in the middle lobes, the apices being untouched. As a rule it took its origin from one of the smaller bronchi; a tuberculous ulcer appeared, which developed and set going the tuberculosis. The disseminated form was frequent, this developing rapidly and spreading over the whole lung. On section, what appeared to be a miliary tuberculosis was seen, but they were really sections of bronchi.

A second form, which was allied to the pneumonic process, was caseous hepatisation, wherein smaller or larger areas were infiltrated with caseous material. Sometimes a whole lobe was filled by it. Another form was the caseous broncho-pneumonia in so-called rosette form, in the centre of which the lumen of a bronchus appeared. Sometimes a collateral inflammation with gelatinous exudation appeared in the neighbourhood of a tuberculous patch.

A form that did not end in recovery was the acute,

with suppuration and wholesale destruction of lung tissue.

Theoretically considered the tuberculous changes were as curable as in intestine, peritoneum, and even the membranes of the brain. Limited tuberculosis of the lung was curable, but if destruction of a large part of the lung had taken place it was difficult for recovery to ensue. Miliary tuberculosis theoretically considered was curable, but it was part of a disease that affected the whole system. The caseous hepatisation might clear up. That this recovery was not accompanied by *restitu ad integrum* was self-evident. A cicatrix must remain at the spot.

Even cavities might heal. When small they might even disappear. Large cavities became smooth-walled and covered by epithelium.

It was further to be considered that only phthisis with lesions in the upper lobes healed. The speaker had never seen tuberculosis of the middle and lower lobes heal. If one looked at preparation of healed phthisis more was found destroyed than one believed from a first glance, because the healthy part had increased by way of compensation and appeared larger than it was in reality.

Some cases had led to controversy. One occasionally found caseous patches in the cicatrices. It was known that the caseous masses might calcify and form concretions. They were surrounded by connective tissue and encapsuled. Not unfrequently tubercle bacilli, which were virulent, were found in old remains. These did not die as assumed by Cornitin three years ago, but remained active. The cavities also might become encapsuled. Sometimes virulent bacilli were found in the walls, as in the case of a man of seventy-eight. The speaker had shown this man as a cured case. According to his view a case was cured when the disease had passed on to a stable condition. When caseous matter and tubercle were embedded in such a firm mass that the tubercle bacilli could not pass out one might consider the case cured. The same might be said of cavities when the bacilli within could only vegetate as saprophytes and could not set up fresh changes. The speaker reported such a case, that of a gentleman who had formerly had hæmoptysis, but who for years had shown no further symptoms. There was a cavity which had probably become encapsuled. Of course the condition might light up again, particularly from some intercurrent illness.

The speaker then passed on to the characteristics of tuberculous cicatrices as compared with others. The badly resolved pneumonias left cicatrices which never, however, lay in the apices. They spread superficially. Syphilitic cicatrices presented the greatest difficulty. There were cases of syphilis which left cicatrices not to be distinguished from those of tubercle. But syphilitic lesions were necrotic in some parts and from this character they could be identified. Sometimes these cicatrices were extraordinarily characteristic. They were limited to lymph tracts and formed reticular tissue.

Hr. Sommerfeld had studied small patches of disease, and found even when very small, that they were surrounded by small-celled infiltration, a sign that the process had extended.

Hr. Hanseemann would not look upon a small-celled infiltration as premonition of the tuberculous process.

When these lungs were examined microscopically, many such were found. Elderly people had rarely an absolutely sound lung. Towards the end they had oedema, aspiration, pneumonia, and bronchitis. It was not infrequent that during life nothing particular was found, whilst after death one came upon caseous infiltration, giant cells, &c. Most people over sixty years of age had some tuberculous change in the lungs, especially if the lymph glands about the hilus were examined.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, April 12th, 1902.

FAT CHANGES IN THE STOMACH.

At the Physical Society Gärber related two experiments on cats with fat. After twenty four hours' fasting they were provided with a meal of fat. Six hours later they were killed, and a weighed quantity of the contents of the stomach taken for analysis for free fatty acids. In one of the cases there was a decided increase of the free fatty acid, while none was observed in the other.

He next took part of the mucous membrane of the stomach, and determined its power of breaking up fat in a test tube. He placed neutral olive oil in a portion of the stomach, and suspended it in a water extract; another portion of stomach was suspended in a glycerine extract and gently shaken for half an hour at 40° Centigrade. As a control experiment another portion of the stomach was boiled, and the olive oil placed in it in the same manner as the fresh experiments. The digestive power of the mucous membrane was then analytically tested with "petrol ether" and the free acid determined. The results were that the conversion into neutral fats as *in vivo* were very slow. The glycerine extract was quite inert as well as the mucous membrane of the second out, as no ferment was found.

DISSEMINATED SOFTENING IN THE FLOOR OF THE FOURTH VENTRICLE.

At the "Gesellschaft der Aerzte" Erben demonstrated on a patient the characteristic symptoms of disseminated softening in the floor of the fourth ventricle. The patient was a strong, well-nourished man, æt. 67, who in April last year was suddenly seized with difficulty of swallowing and speaking after having partaken of a hearty meal. This condition still existed without material change, neither retrograding nor increasing. His speech is indistinct, being of a monotonous, nasal, and drawing character and quite disjointed, although quite intelligent in substance. Swallowing was very difficult, and the saliva dribbled from the mouth. He had also difficulty in masticating, not being able to seize and retain the morsel between his teeth. The mind was unimpaired, and the eyes and the eye movements normal, no changes being observed in the fundus; no photophobia or hyperæsthesia. There was no weakness of the extremities, and he could walk long distances without feeling fatigued; nor did any muscles or nerves seem weak or impaired. The peripheral arteries could be felt in diastole, but were distinctly atheromatous. Heart and aorta were normal; slight cough; and nothing abnormal was observed in the urine. No history of any former disease nor irregularities—alcohol or syphilis. The tongue and lips were

free from atrophy or fibrillary tremor, while the reaction to the Faradic current was normal. All these facts pointed to the paralysis being located to the central neuron of the bulbar nerves, what may, in fact, be termed a pseudo-bulbar-paralysis.

The following symptoms may be selected for differential diagnosis:—

First, only strong currents assisted the act of deglutition, which was not constant at all points. Second, the gums and posterior surface of the pharynx did not react while the uvula was moved on phonation. Both of these conditions indicate a reduction in the reflex action associated with a supra-nuclear break in the connection. There are also symptoms present which indicate a disturbance in the cortico-nuclear part, but might be relegated to the bulbar centres, and may be assumed by a softening at the base, which may be due to a sclerotic condition.

This supposition is supported by the suddenness of the onset, probably due to thrombus, its stationary condition, the age of the patient, and the condition of the vessels observed. The bulbar functions were normally performed and thus by exclusion he was led to diagnose disseminated softening in the floor of the fourth ventricle. Against the diagnosis of Duchenne's form of bulbar paralysis is the symmetry of the paresis.

New Zealand.

[FROM A CORRESPONDENT.]

THE FIRST MINISTER OF PUBLIC HEALTH.

THE report to hand for last year of Dr. J. M. Mason, Chief Medical Officer of Health for the Colony of New Zealand, is the outcome of the introduction of the Public Health Act of 1900, and as Dr. Mason very aptly says—"puts the Colony in the van as regards the consideration of the public health. For many years the medical profession, and those interested in health matters at home have been striving, so far in vain, for the appointment of a Minister of Health. By the Act passed last session this has been accomplished for New Zealand. For the first time in the history of Great Britain and her Colonies, has the physical welfare of the people been elevated to a first place in the consideration of the government. Foreign affairs, mines and agriculture have all had their importance marked by the creation of Ministers holding Cabinet rank to look after their interests; but it has been reserved for New Zealand to create the first Minister of Health." The report is addressed to "The Hon. the Minister of Public Health to His Excellency the Governor," and is not only very full and comprehensive, but displays a literary style which reflects the highest credit on its author. Accompanying the report are excellent maps showing the various districts under the Public Health Act, 1900 and the entire production might safely be characterized as a veritable manual of public health, embracing as it does a full discussion of the subjects of drainage, water supply, disinfection, pollution of rivers and streams, meat and milk supply, disposal of house refuse, and night soil. The chapter on consumption is an extremely interesting one, from which we extract the following: "Another point which is worthy the most serious attention of the Government is the great number of people suffering from consumption who yearly land in th

Colony in the search after health. It has been urged by some that we ought to exclude everyone suffering from consumption. This attitude has the support of many, but I think in most cases it comes of ignorance or non-appreciation of the true facts of the situation. Viewed from the point of international equity it seems to me it would be as unfair as it would be un-Christian to deny any fellow-creatures the beneficent effect of our climate. On the other hand there need be no hesitation whatever in pointing out to the world at large the inhumanity to the sufferers of consigning a person in an advanced stage of consumption to the irksomeness of a long sea voyage and the divorcement from all he holds dear, in the vain will-o'-the-wisp pursuit of the recovery which can never be his." The author of this report has also many useful suggestions with reference to sanatoria for consumptives which will be read with much interest at the present time in this country. Dr. Mason, it may be added, was a distinguished student at Glasgow, taking the M.D. Brussels with distinction in 1888. He holds the D.P.H. Cambridge, and is also a barrister-at-law of Gray's Inn, London. He settled in Australia and on the occasion of the plague outbreak was invited by the New Zealand Government to report on the condition of the Colony, and to assist in forming a Department of Public Health, to which he was appointed Chief Medical Officer. He is to be congratulated on the issue of a report which is not only instructive, but full of interesting detail from beginning to end; the perusal of which will well repay all those engaged in the study of public health matters.

The Operating Theatres.

WEST LONDON HOSPITAL.

UNDESCENDED TESTIS.—Mr. BIDWELL operated on a lad, *æt* 14, with undescended testis on the left side. The other testicle was in the scrotum, but the parts did not show any signs of puberty. The left testicle could not be felt before the operation, but a hernial sac was present. An incision was made over the external ring and inguinal canal, and the hernial sac exposed, and separated from adhesions; on opening this the testicle was seen inside the inguinal canal, and with some difficulty was brought outside. The peritoneum was then divided just above the testicle, and the upper part dissected off the cord as far as the internal ring, where it was tied. The testicle was then freed from all adhesions and its lower border was then found to reach to the root of the penis; in order to bring it into the scrotum the spermatic veins and artery were divided between ligatures and the vas deferens and its artery carefully separated from the upper and middle parts of the testis. In this way the testis was turned upside down, and it was then possible to place it in the scrotum. A silk-worm-gut suture was then passed through the tunica albuginea just at the position of the hydatid of Morgagni, and both ends of this stitch were then brought through the bottom of a scrotum by means of a mounted needle; a bed in the scrotum having previously been made by separating the fascia from the fingers. The inguinal canal was then closed with a few points of silk sutures, and the skin united with horsehair, the wound being covered with a collodion dressing. A special wire cage was then

applied over the penis and scrotum, and extension was made on the testes by means of a piece of indiarubber tubing attached above to the wire cage and below to the gut suture through the tunica albuginea. The whole cage was covered with an antiseptic dressing.

Mr. Bidwell remarked that this method was the most effectual in bringing down undescended testicles. He drew special attention to the method of turning the testicle upside down, thereby gaining a considerable amount of length in the cord. At first sight it might appear that the deliberate division of the spermatic vessels might cause atrophy of the testis, but this was not the case, and practically the procedure was very similar to that followed in excision of a varicocele, where very frequently the spermatic artery was included in the ligature. At any rate, he had performed the operation in a fair number of cases, and had never met with atrophy of the testicle. He did not agree with those surgeons who advised castration in cases of undescended testicle, since he was of opinion that a testicle which had been brought into the scrotum was still of use. He referred to the case of a man, *æt* 25, who had double undescended testicle, and who sought relief prior to his marriage; both testicles were brought into the scrotum by this method and remained there. The patient married and had a family. One reason why the patient just operated on had been brought to Mr. Bidwell was that there were no signs of puberty, although the lad was 14 years of age. He considered that the delay in the descent of the testicle might explain the delay in the advent of puberty. Undoubtedly these cases should be operated on before puberty, since there was then a better chance of the organ developing properly.

ERRATA.—In last week's "Operating Theatres," line 10, for "aphasia" read "aphonia"; line 14, for "caused" read "around."

Anti-Typhoid Inoculation.

SOME interesting figures have just been published by Dr. Wright, Professor of Pathology at the Army Medical School, Netley, showing the results of anti-typhoid inoculation in the case of the 5th Battalion of the Manchester Regiment in South Africa. His observations extended over a period of six months, and the figures relate to a total strength of 747 officers and men. The number of those who submitted to inoculation was 200, and among these only three cases of typhoid, or a percentage of 1.5, occurred; while among 547 who were not inoculated there were twenty-three cases of the disease, or a percentage of 4.2. The influence, however, of the inoculations, appears to be more strikingly shown in the fact that while none of the inoculated died, no fewer than seven cases proved fatal to the uninoculated. Some doubt still remains as to the efficacy of this mode of preventive treatment, but the figures here recorded are certainly worthy of attention.

Peculiar People Sentenced.

A MAN and his wife, belonging to the sect of "Peculiar People," have been found guilty at the Central Criminal Court of "manslaughter by negligence," in that they abstained from obtaining medical assistance for their sick child, and were sentenced, the man to three, and the woman to two, months' imprisonment.

Women Doctors Abroad.

THE Paris Medical School has no less than eighty female students in medicine, and the University of Berlin has close upon 600 young women on its rolls.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25 Os. 0d. Half Page 22 10s. 0d., Quarter Page, 21 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 16, 1902.

THE CAUSE AND TREATMENT OF CANCER.

THE scheme for the organised investigation of cancer which was adopted by the Royal College of Physicians of London a few weeks since has just been formally approved by the Council of the Royal College of Surgeons, so that we are at liberty to consider the methods suggested with this object in view. It is proposed to raise a fund of £100,000 to be administered by a general committee consisting of at least twenty members, and an executive committee of twelve members representing various learned and scientific bodies. Part of the sum to be raised will be devoted to the erection and maintenance of laboratories in which the study of cancer problems will be carried on, and part will be allocated as subventions to similar laboratories elsewhere in the Empire. Assistance will be given to the prosecution of cancer research in various hospitals and institutions approved by the Executive Committee and generally an endeavour is to be made to obtain the co-operation of all whose special studies fit them to aid in the elucidation of the points which require investigation. There will be a consultative staff consisting of such persons, together with representatives of various home and colonial government departments, physicians and surgeons attached to hospitals, statistical experts and others. Already several substantial contributions have been promised to the fund, and as the movement is certain of the support of His Majesty we may confidently anticipate that any difficulty which the raising of such a large sum may present will be successfully overcome. Moreover there are few subjects in which the public are more directly and painfully interested. One of the main features of the scheme is the co-ordination of labour by skilled experts all over the world. Hitherto

this branch of research has been left to private initiative, with the inevitable consequence that much energy has been wasted in going over the same ground owing to ignorance on the part of the investigators of what is being done, or has already been done, elsewhere. From this point of view the present scheme will unquestionably prove of immense utility. The scheme, moreover, is not restricted to providing facilities for purely laboratory work. Our ignorance of the etiology of cancer is such that no man can say whether the secret is one to be unravelled in the laboratory, in the wards, or by more general and comprehensive methods of investigation, such as is afforded, for instance, by statistical research. The clinical observation of cancer patients certainly does not appear to have afforded much assistance, and such suggestions as have been forthcoming have been due to patient laboratory work on the lines which have proved so successful in the study of malaria. The great thing is to ensure that no department of research is neglected, and this, if it be endowed with proper vitality, this scheme should adequately secure. By focussing the expert intelligences of the world on certain problems we shall be doing all that is humanly possible towards the elucidation of questions which have so far baffled investigation, none the less assiduous and patient because it has been carried on by individual effort. By enabling those best fitted for the task to devote more time and energy to the task before them, we may fairly hope to achieve progress and ultimately to attain the goal, which is, first of all, the discovery of the nature of the disease and, should it prove to be transmissible, the means by which the infection is conveyed. That cancer belongs to the class of infective diseases is infinitely probable, and should this prove to be the case we are justified in hoping that the discovery of the means of preventing, if not of curing, the disease will be a natural sequel.

THE MIDWIVES BILL AND IRISH MATERNITY HOSPITALS.

THE Midwives Bill is down for the report stage on June 4th, and there is every prospect of a debate on the proposed amendments which may be of such length as to imperil its safety—especially if the new procedure rules have by that time come into force. As is well known, the Bill has many opponents, and the number of these opponents has not been diminished by the knowledge of the fact that it is in great part directed, not as the preamble says, "to secure the better training of midwives and to regulate their conduct," but to form a foundation stone for future attempts to wring the control of all things medical from the medical profession. The points in the Bill, which make this intent manifest, have been so often dealt with that it is needless to recapitulate them. Suffice it to say, that, in some points, the wish has been father to the clause to such good purpose that the nominal object of the Bill is forgotten, and its preamble stultified. What, but

the pressure of an anti-medical *clientèle*, could have persuaded Mr. Heywood Johnstone, Mr. Schwann and Mr. de Tatton Egerton that it was unwise to incorporate in the present Bill an amendment to the late Bill, which was accepted by these gentlemen, recognising the examinations of the Rotunda and Coombe Hospitals as equivalent to the examination of the Central Midwives Board. As every medical man knows, and as many laymen are cognisant of, the great chartered midwifery hospitals of Dublin have been a household word—not only in Ireland, but throughout the world—on account of the excellence of the instruction they imparted, both to members of the medical profession and to midwives. In consequence, students of medicine, and women proposing to be trained as midwives, have flocked to them in numbers in excess of the residential accommodation of the hospitals. Further, it is well known that the examinations held for midwives, and on which the diploma of these hospitals is awarded, are of such a character as to ensure the efficiency of those who pass it. While the training and discipline are such, that nurses who are trained there know to the full the manner in which their duties should be discharged. Yet in the face of the fact that the nursing *diplomees* of these hospitals are guaranteed by the professional reputation of the hospitals to hold the first rank in the occupation they have adopted, the promoters of a Bill “to secure the better training of midwives” omit—we trust that we need not say refuse—to recognise them unless they pass an examination held by a Central Midwives Board. The hardship and injustice of this is obvious to anyone who has studied the question. The Rotunda and the Coombe Hospitals were instituted in order that, among other things, in the words of the Charter of the former hospital, “by Admitting, and Instructing in such Hospital, Women, who, after some Time spent there, being duly Qualified, may settle in such Parts of our said Kingdom as most stand in need of such Persons, it will be a Means of Preventing the unhappy Effects owing to the Ignorance of the Generality of Country Midwives.” These are the words of the Charter of George II., and yet in one of the earliest Bills of Edward VII. we find an attempt being made to render it penal for these highly-trained nurses to practice in accordance with the directions of the charter under which they have been trained. If it could be alleged that the Rotunda and Coombe Hospitals had failed in their duty, or that their *diplomees* were insufficiently trained, or if any possible slur could be cast upon the character of their examinations, the omission of a clause recognising their examinations could be excused. Further, if it was even possible to state that, as the Bill will not extend to Ireland, it will not affect Irish nurses, an excuse might also be made. But this, too, is impossible. Within the last five years, ninety-one English women, sixteen Scottish, and 182 Irish women, in addition to nine others from different parts of the

world have been trained at the Rotunda alone. These numbers could be enormously increased, by lessening the period of training or by admitting nurses who did not live in the hospital, if the governors were not determined to maintain the highest standard. If the promoters of the Midwives Bill really wish to ensure the training of midwives, why should they penalise such of them as have obtained the best training possible by forcing them to pass two examinations. Further, under the present Bill, it will be impossible for an Irish nurse, no matter what her qualifications, who has not passed the examination of the Central Midwives Board, to attend a case even temporarily in England. Whereas, an English nurse can freely cross to Ireland and practise there. These are injustices to Ireland of a real nature, to which we draw the attention of members of Parliament irrespective of party. It is not too late to have them removed. An amendment will be moved at the instance of the Royal College of Physicians on the report stage of the Bill, and this amendment will be identical in character with the amendment which was accepted in 1900 by Mr. Heywood Johnstone. We trust that the promoters will see their way to accept it. By so doing, they will further the first object for which their Bill has been introduced, and they will go some way towards removing the distrust with which it is regarded.

THE INEBRIATES ACT.

To reform the habits of a nation is notoriously one of the most tedious and difficult of social tasks. In the case of the United Kingdom the habits of drinking alcoholic liquors to excess dates from the earliest period of history, whether that be of Anglo-Saxon, Dane, Norseman, Briton, or of the various other races that figure in our early ancestral records. Of late years the gospel of temperance has been preached far and wide with many substantial and encouraging results. Among the upper and middle classes of society drinking habits have as a general rule decreased to a very great extent, and among the working classes there are many moderate drinkers and total abstainers. For all that, the annual drink bill of the nation is excessive and judging from recent statistics appears to be gradually increasing. The need for continued vigilance and effort on the part of temperance reformers is therefore apparent. The drink question has seemed for many years to have reached the stage when it might reasonably be regarded as ripe for legislation. In spite of that fact however, the wheels of the legislative chariot have lagged in a fashion that would be unaccountable were it not obvious that Parliament is practically powerless to deal with temperance matters in the face of the opposition of the brewing and distilling interests that have a great or even preponderating influence in both Houses of Parliament. Trade interests stop the way for anything like effective drink legislation, and until that fact is realised by the nation at large there is no likelihood of the passage of any comprehensive measure of re-

form. At the present moment a Bill dealing with some minor aspects of the question is under the consideration of Parliament. It cannot be regarded, however, in any sense as a broad and statesmanlike attempt at solving a problem that demands immediate and drastic treatment. A review of the past history of temperance legislation tends to the conviction that we must be content with small mercies where the regulation of the drink traffic is concerned. The Inebriates Act of 1898 is a piecemeal contribution which may perhaps one day be capable of amendment in a sufficiently wide and practical manner to be productive of solid benefit to the nation. Reformers for the most part recognise that the measure in question is of a tentative nature. Armed by the powers it confers the Corporation of Glasgow equipped a house in the country in 1900 as an Inebriate Reformatory, which was licenced to accommodate twenty-eight male and thirty female inmates. In the following year the certificate was cancelled in favour of a new one for the accommodation of fifty-eight female inmates. Section 23 of the Act of 1898 entitles the managers to state what class of persons should be eligible for the home, which was determined as follows:—

- (1) The inmates must be persons belonging to Glasgow, and must be sent for trial to the Sheriff of Lanarkshire through one of the City Police Courts;
- (2) preference will be given in every case to persons who, while habitual drunkards, are of such character and disposition that it may be reasonably expected, if cured of their intemperance, they would be able to take their places in society as self-supporting citizens;
- (3) the persons admitted must not be known thieves or otherwise belong to the criminal classes;
- (4) in respect that other institutions are available for prostitutes, women of that class cannot be received;
- (5) persons suffering from infectious or other serious disease cannot be received.

In practice, the Committee found it impossible to enforce these conditions. They report that after a few months' experience they were disappointed at finding that very few of the women submitted to them by the police magistrates were of such character and disposition that if cured of their intemperance there was reasonable hope of their supporting themselves. It was found that the great bulk of the women were paupers and about half of them had been convicted of importuning. Indeed, the question of inebriety in women is nearly always complicated by that of sexual immorality and its attendant disabilities. The committee found that Clause 2 of their conditions became unoperative while Clause 4 was abandoned. The main practical conclusion of the committee appears to be that the most hopeful class of cases was outside the Inebriates Acts provisions, namely, those who have not been convicted of drunkenness in a police court four times within twelve months. Their general attitude may be gathered from the statement that they have appointed a sub-committee to consider and report as to suggested amendments to the Act.

This Glasgow experiment is of distinct value as paving the way to a more comprehensive and practical future in the control of habitual drunkards. It is to be hoped that a similar conscientious attempt will be made in other parts of the United Kingdom to reduce the excellent underlying principle of the Inebriates Act to a sound working basis.

Notes on Current Topics.

Gauze Packing in Appendicular Surgery.

THE employment of iodoform gauze as a packing or for drainage purposes, in operations on the appendix, is generally regarded as the *dernier cri* of modern surgery, and its virtues have been extolled far and wide. Dr. R. T. Morris, of New York, takes quite a different view of the value of this substance from a surgical point of view. If, he says, we take ten strong healthy policemen from the street at nine o'clock this evening and put half-a-yard of gauze into their abdominal cavities respectively under the most careful antiseptic precautions we shall find by nine o'clock to-morrow evening that "we did not get them in time." He maintains that the use of gauze was introduced as a rude method for obtaining the desired result, but is in truth open to the gravest objections. By adding iodoform to the gauze we add another element of distress for the patient who is thereby exposed to insidious iodoform poisoning. In iodoform poisoning, he remarks, the wound looks uncommonly well, but the patient does not. He dilates eloquently upon the distress which is inevitably associated with the presence of a mass of foreign body in the delicate peritoneal cavity, to say nothing of the misery incidental to its removal and replacement. He accuses the packing of causing intestinal obstruction by direct pressure, of setting up adhesions which are sure to be a source of annoyance and even danger in after-life, and, indirectly, of leaving a permanently weak spot in the patient's abdominal wall with consequent ventral hernia. In spite of this formidable indictment Dr. Morris does not feel justified in urging the instant abandonment of gauze packing, which forms too integral a part of present-day surgical practice, but he strongly advises working in view of giving it up as soon as experience proves that this step can be taken with safety. He invites us to study the statistics of surgeons who employ gauze and those who employ it not, in order to arrive at a trustworthy conclusion as to its efficacy for the purposes for which it is used.

The War against the Yellow Fever Mosquito.

ACCORDING to the New York *Medical Record* the campaign against the *Stegomyia* mosquito in Havana has resulted in a very marked diminution in their numbers. In 17,000 houses examined by the "mosquito corps" during the month of January, in only 411 were larvæ found, whereas formerly they were discovered in nearly every instance. As a result of this systematic mosquito destruction not a

single case of yellow fever has occurred in Havana for nearly six months, and in ten months, April to February, only five deaths were recorded as against an average 457. The sanitary department has worked exclusively on the assumption that the mosquito is the sole agent by which yellow fever is transmitted, and has entirely disregarded the question of "fomites." The measures of mosquito destruction employed include drainage of damp places, removal of receptacles for standing water, the free use of petroleum, and the destruction of adult insects by formaldehyde, sulphur or the fumes of burning pyrethrum powder. The success of these measures is encouraging in view of the campaign which is now being waged against the malaria-bearing mosquitos, but, considering the immense and ill-defined area over which the latter are met with, and the mechanical difficulty of compassing their extermination, we cannot well hope for results at all comparable to those achieved in Havana. We cannot flood Central Africa with paraffin, nor can we eliminate lakes and marshes from its geographical conformation, but by reducing the foci of infection we may at any rate hope to diminish the proportion of infected mosquitos.

Responsibility of Medical Men in Abortion Cases.

THE limits of what constitute a professional confidence are at times extremely hard to define. It often happens that a medical attendant is made the confidant of criminal acts in the course of his professional duties; and there is no law, so far as we are aware, that binds him to play the part of detective in disclosing any knowledge that has come into his possession in that way, although there are some offences such as murder, which every prudent practitioner would at once disclose. The most common case of the kind in which a medical man is called upon to decide as to the preservation of secrecy or otherwise is where a woman has procured abortion upon herself by some means or other. An illustration of the difficulties arising from such an incident has lately been afforded in the Coroner's Court at Derby. A medical man was called to attend a woman, who a day or two afterwards confessed she had taken some powders sold by a patent medicine vendor in the town, and had procured abortion. He did not tell the husband of the state of affairs for a fortnight, nor did he inform the relatives to whose house the patient was then removed. Lastly, he did not inform the medical officer of the infirmary to which she was finally taken, and where she died, of the cause of her condition, although he stated that she was suffering from pelvic cellulitis. He excused himself to the Coroner on the ground that the matter was one of professional confidence, and he did not regard the woman's condition as serious enough to warrant the taking of depositions. Public opinion will doubtless commend him for his reticence in so far as the relatives were concerned, but we see no reason why information, even of this delicate

kind, should not have been imparted by him to the other medical men under whose care the patient subsequently came. Such an act could never be construed as a breach of confidence. Nevertheless, it is preferable that medical practitioners should err on the side of discretion rather than the contrary, but the fact must not be overlooked that by remaining the sole depositary of such a secret the practitioner incurs the risk of passing for an accomplice, besides making himself an "accessory after the fact."

Poisoning of a Family by Carbon Monoxide.

A PAINFUL tragedy of poisoning by coal gas occurred in Dublin on the 5th inst. Its victims included a whole family of the number of three. When the dead bodies of the occupants were found the gas was still escaping, and the irregular state of the gas connection satisfactorily explained the occurrence of the escape. But the peculiar feature of the fatality, which must prove interesting to the chemist and physiologist as well as to the pathologist and sanitarian, is that the evidence elicited at the inquest showed that the bodies all displayed the characteristic appearances found in cases of poisoning by carbon monoxide. This peculiarly deadly gas possesses a special interest for the physiological chemist, as it displays the special latent activity of "unsaturated" chemical compounds, and a unique form of affinity for the hæmoglobin of the red blood corpuscle. It is well known that the great physiological importance of the latter is due to the fact that it possesses a special attraction for oxygen. Accordingly it readily takes up the latter—in the capillaries of the pulmonary air vesicles—and carries it off to those of the various tissues. The various cellular constituents of the latter display their selective power by unloading the hæmoglobin of its cargo of loosely-combined oxygen and leaving it free for the further exercise of its functions as it returns to the heart through the veins. The unsaturated gaseous compound, CO, possesses the mischievous property of a greater affinity for hæmoglobin than the very important physiological one displayed by O-gas. Accordingly, if a person inspires a considerable quantity of CO-gas, the physiologically indispensable oxygen finds no admittance to the red blood corpuscles, and the inevitable result is that all the vital functions are at once arrested. And another interesting—and unique—peculiarity presents itself in the fact that the colour of CO-hæmoglobin is approximately identical with that of O-hæmoglobin. The naked eye cannot be relied on to distinguish; examination with a spectroscope alone displays to the skilled observer a characteristic trait. This is the reason of the peculiar arterial—more or less modified scarlet—tint displayed by the blood of the victims of poisoning by carbon monoxide. This tint was conspicuously present in the cases of all three members of the O'Neill family. The Alliance Gas Co. has already been subjected to severe criticism in connection with this fatal tragedy; based on the

allegation that, of recent years, they have been serving their customers with a 20 per cent. addition of water gas, which is cheaper in production, and whose presence adds 8 per cent. to the normal proportion of 6 per cent. of carbon monoxide present in the ordinary coal gas. The various inferences are obvious.

Sentimentalism in Medical Literature.

It is to be hoped that medical authors will always bear in mind that science, especially medical science, does not lend itself to florid writing which, when indulged in, has for effect merely to obscure the meaning, if any, of the dissertation. A little exuberance in speaking is pardonable for *verba volant* but *scripta manet*. Examples of the tendency to which we refer are not hard to find in our everyday medical literature. In an instance quoted by the *Boston Medical and Surgical Journal* the author relates that he was once engaged in "studying a profoundly diseased ovary, under a power of 400. There was presented a picture of almost dazzling brightness. Long branching protoplasmic bodies of exceedingly delicate and exquisite organisation, winding in all directions and in most graceful curves. It made a fairland of beauty. It was a forest of wonderful structures. . . . The microscope reveals the pathological change, clinical history gives the life reflection and makes the momentous reverberations of the almost tragic records." Now as a description of a diseased ovary the above is decidedly poor, and would confuse and possibly madden the student intent upon acquiring an inkling of the actual condition of the diseased organ. It is not even clever, because nothing is easier than to write at random without taking the trouble to describe appearances accurately and briefly. If adjectives are the enemies of nouns, imagery is the enemy of precision. Intending authors will please take note!

The Control of Medical Education.

THERE is an undoubted tendency in many quarters to consider that the guiding restraint which the General Medical Council exercises over matters of medical education is an unwarranted piece of interference with the rights of the different qualifying Bodies. The attempts of the Royal Colleges of London to defy the authority of the Council has served to bring into prominence the fact that there are many other Bodies, who have also neglected to follow its regulations, and that there are many more who would like to do the same. Unfortunately, such attempts are encouraged by the existence of a more or less prevalent notion that the General Medical Council is not what it ought to be, and that it does not guard the interests of the profession in the manner in which, for instance, the Incorporated Law Society guards its branch of the legal profession. There may be an element of truth in this, for the Council has undoubtedly a difficult card to play, in the selection of which there are too many advisers. Still, the fact that Parliament and Ministries are indifferent to

the demands of the Council is no reason for thinking that indifference on the part of the medical schools of the country will improve the state of affairs. At the present time there are some nineteen degree-conferring bodies—a number which is being every year added to, and each of these bodies are competing with one another for students. Can any sensible man have any doubt as to what would be the condition of medical education if each of these bodies were allowed to pursue an untrammelled course of curriculum shortening? In our opinion, the immediate result would be the marked deterioration of medical education; and the remote result—the reaction of public opinion leading to the establishment of State-controlled one-portal system. Would the various Corporations and Universities like such a state of things? If not, should they not admit once and for all, that a central authority is necessary, and that it is better that the medical profession should control this central authority than that laymen should do so. A persistent refusal to recognise such a necessity, and an equally persistent refusal to allow the Council to constitute such an authority, will, in the end, tend to bring about the substitution of an authority over which the control of the medical profession will be similar to their control over the clauses of the Midwives Bill.

American Sexual Literature.

A MOST extraordinary work has been recently published by Messrs. Saunders and Co., entitled "The Four Epochs of Woman's Life—a Study in Hygiene," written by a female doctor of the name of Anna M. Galbraith, who, it is unnecessary to say, hails from America. From the preface we gather that it is intended for; the perusal of women, young and old; from the contents we perceive that it is quite unfit for such a purpose. It is slightly crude—to say the least of it—to tell a young girl that certain "men early in their career are apt to become infected with some of the venereal diseases, or perhaps with all of them—gonorrhœa, syphilis, and so forth," while it is contrary to the moral notions of many to advise a shortly to be, or just, married woman that "it is better that the first year of married life should be allowed to pass without conception taking place." And then the reason which is given for this advice—"Children born during the first year of married life seldom equal in health children born of the same parents later." The medical knowledge of Dr. Galbraith appears to be as peculiar as her ethics. We learn among other things that a "virtuous young girl," "in her menstrual periods has had to do only with the secondary phenomena; with the expulsion of the ova not at all." The most curious part about this precious work is not why it was written. That is sufficiently obvious. It is that John H. Musser, M.D., Professor of Clinical Medicine in the University of Pennsylvania, writes, in an introductory note that Dr. Galbraith's truths should be known by every woman. We must protest against such a book being in any way associated

in the minds of the public with the teaching or opinions of the medical profession.

The Foundation of Oxford.

THE munificent bequest of the late Mr. Cecil Rhodes to the great senior English University must, necessarily, call special public attention to this grand old institution—to its past history, its present standard of progress, and its probable future usefulness in training the mental capacities and capabilities of the flower of the youth of the great British democracy. In this connection it is interesting to note—more especially as recent events have tended to the development of a better understanding and a more just appreciation of the respective qualities of the inhabitants of the sister isles—what share the influence of Ireland had, in the happy days of its learning and prosperity, on the diffusion of learning and civilisation in Great Britain. It is a historic fact that when Alfred the Great felt the inspired call to introduce the light of knowledge and learning into the dark regions of the territory which the will of Providence had called him to govern, he acted very much as Peter the Great of Russia did long centuries afterwards, in the best interests of the vast population of his empire. The latter monarch, feeling the want of the advantages of commerce and civilisation among his people, came to Holland and to England to study the art of shipbuilding and the other adjuncts of modern civilised commercial intercourse. With what success his very meritorious efforts were crowned is well known to every reader of modern history. It is less well known—the fact is not specially emphasised in our school and college histories—that when the great Alfred wished to introduce the blessings of learning into his territory and to diffuse them among his people, he came over to Ireland to be educated himself, and imported an Irishman who founded the University of Oxford.

A Suggested Antivaccinist Hospital.

THE newspaper press of the United Kingdom has naturally enough, been flooded with suggestions of persons who have ideas of their own as to the best way to avert or check the wave of small-pox now sweeping over the Metropolis with such disastrous effect. Through all this fanciful tangle of crude reasoning and imperfect knowledge there now and then struggles a passing gleam of humour. One of the most weirdly comical suggestions yet advanced has come, apparently with all seriousness, from an anti-vaccinationist, who proposes that all small-pox patients who have not been vaccinated should be treated apart in a hospital of their own. The author of this phantasy apparently imagines that modern medicine is wrong in its treatment of small-pox no less than in its method of prevention and of mitigation by means of vaccination. Further, he seems to assume that the anti-vaccinationist who is right in condemning vaccine must have his own appropriate curative methods for small-pox. It is clear that were those unprotected against small-pox

classified in this way the task of the statisticians would be lightened. but that is the only shred of advantage that can be gleaned from the proposal. If the anti-vaccinationists want to die in their own way, Mr. Balfour has made it possible for them to withdraw themselves from the action of the law. It is clear, however, that the present state of educated public opinion will not allow them to do so at the public expense. In an anti-vaccinationist hospital, moreover, they would have to undergo isolation and disinfection for Mr. Balfour has not yet dismantled the office of medical officer of health.

Contract Medical Practice at Norwich.

THE old proverb "God helps those who help themselves" applies with special force to members of the medical profession. It has been seriously taken to heart in Yarmouth, where the medical men have for several years past adopted a resolute attitude with regard to the "sweating" of the profession by the friendly societies. Indeed, it seems not unlikely that the burning question of medical contract practice has been to a great extent settled by the decision of the General Medical Council, in November last, in "the Yarmouth case," by which a medical man of the town was convicted of infamous conduct in having been associated with a lay society which systematically practised canvassing in order to obtain patients. It is satisfactory to note that a similar principle of self-help has been adopted by the medical men of Norwich, who have formed a local union of their own wherewith to rout the friendly societies' selfish policy and to uphold the honour and dignity of their own profession. A Public Medical Service has been organised in Norwich to provide for the medical wants of poor persons unable to pay the minimum fees of general practice. This plan offers a way out of the wood to former officers of medical aid societies who join the new service. Its great importance lies in the recognition of the fact that medical men must trust for defence to their own right arms. The General Medical Council, as at present constituted, may control but certainly does not defend. The example of Yarmouth, Norwich, Eastbourne, Coventry, and other towns, where medical men have organised their own associations for attendance on the poor, deserves to be followed in all parts of the United Kingdom.

Variolous Vaccine.

It has long been suspected that vaccine was in reality small-pox modified by passage through the organism of the cow, and this view has been greatly strengthened by the success of recent attempts to produce a vaccine by the inoculation of calves with variolous matter. We cannot quite understand the apologetic attitude of the Government when questioned on the experiments made by Dr. Copeman, of the Local Government Board, experiments which are a credit to him and to the department with which he is associated. Only unreasoning prejudice could take exception to these experiments, which were

indeed indispensable to the elucidation of sundry problems connected with the nature and production of vaccine lymph. If, as suspected, vaccine be merely the modified virus of variola there is, of course, the possibility that its evolution in the human body might restore its primitive infective properties, but there is absolutely no evidence that such is the case, and indeed, were it so, the close observation to which the action of this lymph was subjected could hardly have failed to detect it. It follows that there is no scientific objection to the employment of such lymph although it is no longer utilised, in deference, we suppose, to popular sentiment; but it is, after all, a matter to be discussed on scientific grounds, and not made the pretext for harassing a Minister who can but repeat what he is told by his subordinates.

The Royal Orthopædic Hospital.

THE affairs of the London Royal Orthopædic Hospital remain in an unsettled state. Last week the annual general meeting revealed a great amount of dissension. The dispute, as usual, raged over the question as to the advisability of the sale of the hospital premises. Readers may be reminded that three years ago the then Committee wished to sell the site for £28,000. They were defeated, and retired in favour of Mr. Harry H. Marks, a gentleman well known in financial circles. The new Committee shortly afterwards declared their intention to sell. A year ago an attempt was made to sell for £37,700, and now the Committee wish to accept £40,000. The opposition has thus sent up the selling price of the hospital no less than £12,000. They contend that the premises are worth more. There is no compulsion to sell, and the property is in so fine a position that its value is likely to go on increasing for many years to come. On the other hand, to dispose of the endowment of the charity, which in this case consists of a highly valuable freehold, in order to buy a leasehold and pay rent, seems to be an unbusiness-like proceeding most disadvantageous to the hospital. The selling of the site on lease would, on the other hand, be a reasonable and prudent method of dealing with the property.

The Surgical Treatment of Bright's Disease.

SOME further very interesting statistics of the results of the surgical treatment of Bright's disease have been lately published by Dr. George Edebohls. His statistics are increased in interest by the fact that he claims to be the first person to treat chronic Bright's disease by operation, and that he has already published the results of cases in which the cure of this disease had resulted from the performance of nephropexy. In the present list, the result of eighteen operations is given, and it must be candidly confessed that these results are of a most encouraging nature. In eight of these cases, albumen and tubecasts finally disappeared from the urine at an average interval of four and a half months after the operation. While the average period which had elapsed in

each case between the operation and the last occasion on which the urine had been examined was 44½ months. In the remaining cases the results were not so definite. In some the patient's condition was much improved, in others there was no improvement, but in no case did death result from the operation. Dr. Edebohls considers that the increased and adequately maintained blood supply to the kidney which the operation establishes, leads, most probably, to the gradual absorption of the interstitial or intratubular inflammatory products, thus freeing the tubes and glomeruli from external compression and distortion, and permitting the re-establishment in them of a normal circulation.

The Passing of the "Conscientious Objector."

"THERE is a silver lining to every cloud" is a motto that may be applied with some sort of aptness to the present small-pox epidemic in London and other parts of the country. The one cheering feature of this unhappy visitation is that it will almost infallibly sound the death-knell of that curious hybrid the "conscientious objector." The term "infallibly" has been used because it seems hardly possible to doubt that after the experience of the outbreak that is still raging in the metropolis no Government could venture to propose the extension of the five years' lease of life which was originally guaranteed to its monstrous offspring by Mr. Balfour's Vaccination Act. In 1903 the "conscientious objector" reaches the end of his allotted span, and will then pass peacefully away unless Mr. Walter Long, or some other Secretary of the Local Government Board, has the temerity to propose for him a fresh lease of life. Since his appearance upon the scene he has been the butt of unceasing sarcasm and ridicule. Perhaps the unkindest cut of all has been the conduct of the magistrates, who have refused all sorts of anti-vaccinationist objections because their intellects have not been nimble enough to justify their claim to conscientious objection. There can be no doubt that the renewal of the clause in its present form would give rise to great dissatisfaction, not only in the metropolis, but generally throughout the United Kingdom. It was passed in the teeth of the vigorous opposition of the medical profession.

Small-pox in London.

HAPPILY, the London outbreak of small-pox shows at length some signs of steady diminution. The returns for last week showed a marked decrease on those of the previous week. At midnight on Saturday there were 1,437 patients under treatment in the Asylums Boards hospitals. It may be hoped with some amount of confidence that the present fall may point to the beginning of the natural decline that may be expected in the natural course of things during the summer months. For all that the serious nature of the situation must be realised, and the present fall may simply mean a temporary lull. Whatever decrease may take place during the summer, there is

reason to believe that the epidemic will break out with renewed violence when the winter comes round again. Since the beginning of the outbreak in August last 5,925 cases have been admitted to the Asylums Board Shelters, and of that number 906 died.

The Medical Department of the Navy.

By Order in Council, dated March 24th, the new regulations for the medical service of the Navy receive their *exequatur*. These regulations, so far as admission to the Service is concerned, do not differ in any material respect from those previously in force, but power is reserved to the Admiralty should it at any time be considered expedient, to admit annually two candidates to be nominated by schools of medicine in the United Kingdom, such candidates to have satisfactorily filled the post of house surgeon in a large civil hospital for at least six months. Also not more than six candidates specially recommended by such Colonial Universities as shall be selected, whose qualifications are recognised by the General Medical Council. An increase in pay all round is provided. Hitherto the pay on entry has been £209 17s. 6d. per annum; in future it is to be £255 10s. A similar proportional increase has been made as follows:—

	£	s.	d.	£	s.	d.
After 4 years' full-pay service ...	0	17	0	310	5	0
8 " " " " " " " " " " " "	1	0	0	365	0	0
Staff surgeon :						
On promotion ...	1	4	0	438	0	0
After 4 years' full-pay service in rank ...	1	7	0	492	15	0
Fleet surgeon :						
On promotion ...	1	10	0	547	10	0
After 4 years' full-pay service in rank ...	1	13	0	602	5	0
After 8 years' full-pay service in rank ...	1	16	0	657	0	0
Deputy inspector general ...	2	2	0	766	10	0
Inspector general ...	—	—	—	1,300	0	0

Consolidated.

The half-pay gratuities on retirement, retired pay, and allowances are left unchanged.

Gynæcologists as Surgeons.

THE question whether gynæcologists *qua* physicians are entitled to perform operations on their hospital patients, a question which was long since decided in their favour in the metropolis, has just given rise to a heated controversy at Lincoln. Ultimately, in spite of persistent opposition, the common-sense view has prevailed, and it has been decided that it is not outside the province of a physician to perform gynæcological operations. This is as it should be, but it would greatly simplify matters if gynæcologists adopted the view that their specialty is in reality a department of surgery, and qualified accordingly. Abroad both obstetricians and gynæcologists are formally recognised to belong to the surgical staff, and it is a relic of an almost forgotten past in this country that they should continue to be recruited from among the physicians.

THE late Captain Henry Martin Turnor, of Eastbourne, of the 1st Dragoon Guards, who died on

January 7th last, aged 89, and whose estate has been valued at £479,024 7s. 7d. net, has bequeathed £5,000 to the London Hospital, and £5,000 each to the Royal Hospital for Incurables, the Hospital for Consumption and Diseases of the Chest, Brompton, and the Victoria Hospital for Children.

PERSONAL.

DR. HENRY CARSON, of Forest City, Pennsylvania, has just died at the age of 108 years.

SIR JOHN BURDON SANDERSON, F.R.S., has been elected an honorary member of the Danish Royal Society of Science.

MR. F. MARSH, F.R.C.S., will deliver the Ingleby Lectures at the University of Birmingham on May 27th and June 3rd.

SIR FREDERICK TREVES is to take the chair at the second annual dinner of South African Civil Surgeons on June 9th at the Hotel Cecil.

DR. JAMES C. WHITE has resigned the Professorship of Dermatology at the Harvard Medical School, a post which he has held for thirty years.

WE regret to learn that the son of Dr. Gill, of Limehouse, has been the victim of a fatal accident, he having been knocked off his bicycle and killed.

LORD MOUNT-STEPHEN has intimated his intention of setting apart securities, representing about £30,000, so as to secure a yearly donation to the Royal Infirmary of Aberdeen of £1,000.

DR. JOHN B. MURPHY, the famous Chicago surgeon, has had conferred upon him the Lestare Medal, which is in the gift of the University of Notre Dame, "in recognition of his merit as a Christian gentleman and of his great work in medical science."

DR. JOHN A. MACDONALD, who has resigned the position of workhouse medical officer at Baltinglass, has been presented with an illuminated address by his former fellow-officers in the union on the eve of his departure for Leeds. The extern officials subscribed to the address, which was handsomely illuminated and framed.

Lunacy Department.

THE DIETING OF PAUPER LUNATICS IN SCOTLAND.

IN the form of a Supplement to the Forty-third Annual Report of the Commissioners in Lunacy for Scotland, there has been published an elaborate and interesting account of an inquiry by Dr. James Craufurd Dunlop into the dieting of pauper lunatics in asylums and lunatic wards of poorhouses. The report, in which there is embodied a description and criticism of the dietaries of all these establishments, is founded on statements incorporated in schedules which were issued by the Board of Lunacy two years ago, and the inquiry was directed towards ascertaining how far the dietaries met the requirements of the inmates of these institutions. The procedure followed was to enquire minutely into the existing diet scales and to compare their energy value with a standard accepted as being suitable for men doing similar work to that usually executed by pauper lunatics. Dr. Atwater's standard for men doing

light labour is 3,100 calories, and Dr. Dunlop came to the conclusion that the average asylum dietary for male pauper patients should have an energy value of 3,800 calories, and this standard has been practically verified by the acquired results, which show the average of all the male dietaries to be 3,335 calories. In concluding his report, Dr. Dunlop makes the following suggestions for ensuring the proper feeding of pauper lunatics, viz.:—(1) Bread should be given *ad libitum* with all meals; (2) 24 ozs. of meat, uncooked, without bone, should be the minimum weekly allowance; (3) a fish dinner or a fifth meat dinner should be given weekly; (4) porridge and milk must be given at least once daily; (5) the minimum weekly allowance of potato should be 3 lbs., and of other fresh vegetables 1½ lbs.; (6) tea or coffee or cocoa should be served *ad libitum* twice daily; (7) the minimum weekly allowance of butter should be 5 ozs.; (8) the proper variation of diet should be insisted on; and (9) extra food for working patients. Besides an unlimited supply of bread with every meal, he recommends that the national dish (porridge and milk) should be freely used. Of the various dietaries eleven are in excess of the standard adopted, thirteen are near it, and fifteen are deficient. In the case of the excessive dietaries the average weight is more often above the standard; and in the case of the deficient dietaries it is nearly always below the standard. There is a great variety in the dietaries, but some are not too well arranged, some might safely be reduced, others with much advantage increased, and natural distinctions are not always made between the sexes, the employed, and the idle. In one asylum, strange to say, the female patients get bread daily to dinner, while the male patients only receive it when there is no potato. Surely this arrangement should be reversed. In some instances Dr. Dunlop criticises the smallness of the vegetable supply, but it must be taken into consideration that the schedules were filled up at the season of the year when vegetables are very scarce, and we believe this accounts for the shortage in that direction. Of course, in such a report, there are bound to be certain inaccuracies, and it cannot be regarded as being absolutely correct. However, the deviations can all be easily put right, and we have no doubt a careful study of the report will suggest further improvements.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

NATALITY IN GREAT BRITAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I agree with your correspondent "Quersens." There are undoubtedly always two sides to every question; there indeed are many sides to most, and probably none has more sides or is capable of being looked at from more distinct points of view than the question of population and its restriction by artificial means. There is first the personal question. The wife, the husband, and the offspring—how are the moral and physical welfare of each of these affected by limitation of the family? There is secondly the question of the effect upon the nation; and there is lastly the question of the fate of modern civilisation. What is to be the final issue if all the now advancing peoples persist in following the example of dying France and in carrying the narrowest form of egoism to its logical conclusion? If checks upon reproduction were used only with wise prudence based upon scientific considerations, the question would be different. The tendency is not to have a small family but to have no children, or at most only one or two. The aim is not merely to avoid undoubtedly hurtful physical and mental stress and strain, but to shirk all responsibility whatever as parents, and to seek above all things a life of ease, of luxury, and so-called pleasure. That this course does not bring real happiness every competent observer of sufficient experience will, I think, agree. The healthy matron, surrounded by her crowd of children, often presents a picture of satisfying

domestic contentment, and presents a great contrast to the artificially barren wife full of her own selfish unsatisfied desires, or the mother of one or two spoilt brats, a source frequently of more anxiety than a healthy brood of twelve.

In France we have on this subject an object lesson on the biggest scale—a lesson which her own men of science have not altogether neglected. Those of your readers who care to see this question from the point of view of the French savant cannot do better than read M. Edmond Demolins's work, "*A Quoi Tient la Supériorité des Anglo-Saxons*," a translation in English of which has been published under the title "*Anglo-Saxon Superiority*." Curiously Mr. Bodley in his much lauded work, "*France*," has almost entirely ignored the population question, and by thus leaving out of consideration a factor of supreme importance in drawing historical deductions has depreciated, if he has not entirely destroyed, the value of his arguments.

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

March 9, 1902.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Would it not seem to be a law of nature that as soon as the individual members of a community take a prophylactic interest in the question of reproduction, they are fatally condemned to be "wiped out" or absorbed by less intelligent and more prolific races? One may even see in this automatic nation-suicide a natural law adverse to the development of too high a standard of intellectuality in a particular race so long as other races remain behind in psychical evolution. If all races were equally prudent it would perhaps be consistent with national stability, as well as with individual comfort, to strictly limit the output of children, but as far as we can learn from history the too-advanced nations are destroyed before their doctrines have had time to permeate their neighbours.

Nature seems to insist on man drinking the cup of life to the dregs, and as soon as man, obeying his desire to make the best of this world, studies his own interests instead of those of his race, that nation is doomed.

It is customary to speak on this subject as if the birth-rate were dependent on the will-power of individuals, ignoring the fact that our evolution is accomplished in strict conformity with immutable laws which allow no scope for individual initiative. If a decreasing birth-rate be a sign of national decay, it is merely an indication of senility, and who shall pretend to resist the advance of age and the changes associated therewith?

The problem is too vast for profitable discussion. We can see but darkly, and wonder why men should wantonly introduce beings into the world which is the theatre of such harrowing experiences.

I am, Sir, yours truly,

NEOPLASM.

[No useful purpose can be served by discussing the question from this abstract transcendental point of view. We hold that volition is not a *quantité négligeable* in this matter, and that "harrowing experiences" are compensated by agreeable interludes.—ED.]

RABELAIS AS A MEDICAL WRITER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The allusion to "Rabelais as a Medical Writer" in the last issue of THE MEDICAL PRESS AND CIRCULAR recalls the restless and inquiring spirit of the age of this very remarkable man, when the recent introduction of printing and the exodus of Greek scholars and Greek manuscripts from Constantinople, which followed its capture by the Turks, had sown all Western Europe with "dragon's teeth." The series of earthquake waves of thought—political, social, philosophical and theological—which rapidly followed soon caused the development of so great a degree of mental friction in all directions as to raise the temperature of the whole intellectual atmosphere far above the boiling-point. And, as necessarily occurs during every process of

violent ebullition, a large quantity of intellectual dregs was brought to the surface; while at the same time the general intellectual activity was increased some wonderfully inspired bubbles were thrown to a great height—and often flashed forth richly artistic colours before they burst or disappeared; and the really valuable and nutritious portion of the liquid was the portion that remained excluded from the general gaze. François Rabelais was born in 1483, the same year in which Martin Luther first saw the light: and he died in 1553, the year in which Michael Servetus was burned for heresy at the prosecution of John Calvin. The average reader who goes to the "Works of Rabelais" for enjoyment of the buffoonery and obscenity in which, unhappily, they too largely abound, is seldom cognisant of the fact that the author was one of the most learned men of his generation; that, like the great philosophical reformer, Lord Chancellor Bacon, he had "taken all knowledge for his province"; that he had turned from theology and law to the study of medicine, as offering the widest field of genuine knowledge which could be cultivated in this world; and that his coarse buffoonery and gross indelicacy are probably, in every instance, but the reflex of his contempt and scorn of the cant and corruption which he saw everywhere around him. The inspiration of his indescribable work was identical with that of the "English Rabelais," Jonathan Swift. The heroic deeds of Gargantua and Pantagruel grew from the same intellectual germs as did the voracious travels of Lemuel Gulliver. But even medical men, who while away an evening hour over the fantastic creations of Rabelais seldom notice or rarely remember that its pages include the best compendium of the physiological knowledge of his time which has descended to us. I quote from the reprint of Ozell's edition, brought out in 1738 by an enterprising Dublin printer and bookseller:—

"The Intention of the Founder of this Microcosm is to have a Soul therein to be entertained, which is lodged there as a Guest with it's Host, it may live there for a while. Life consisteth in Blood, Blood is the Seat of the Soul; therefore the chiefest Work of the Microcosm, is to be making Blood continually. At this forge are exercised all the Members of the Body; none is exempted from Labour, each operates a-part, and doth it's proper Office. And such is their Hierarchy, that perpetually the one borrows from the other, the one lends the other, and the one is the other's Debtor. The Stuff and Matter convenient which Nature giveth to be turned into Blood is Bread and Wine. All kind of nourishing Victuals is understood to be comprehended in these two, and from hence in the *Langue Goth* is called *Campanage*. To find out this Meat and Drink, to prepare and boil it, the Hands are put to work, the Feet do walk and bear up the whole Bulk of the corporal Mass; the Eyes guide and conduct all; the Appetite in the Orifice of the Stomach, by means of little sourish black Humour (called Melancholy) which is transmitted thereto from the Milt, giveth warning to shut in the Food. The tongue doth make the first Essay and tastes it; the Teeth do chew it, and the Stomach doth receive, digest and chillify it; the Mesaraick Veins suck out of it what is good and fit, leaving behind the Excrements, which are, through special conduits for that purpose, voided by an expulsive Faculty; thereafter it is carried to the Liver, where it being changed again, it, by the Virtue of that new Transmutation, becomes Blood. What Joy, conjecture you, will then be founded amongst those Officers, when they see this *Rivulet of Gold*, which is their sole Restorative? No greater is the Joy of Alchemists, when after long Travel, Toil and Expence, they see in their Furnaces the Transmutation: then it is that every Member doth prepare itself, and strive a-new to purify and to refine this Treasure: The Kidneys through the emulgent Veins draw that Aqueosity from thence which you call Urine: and there send it away through the Ureters to be slipt downwards; where in a lower Receptacle, and proper for it, (to wit the Bladder) it is kept, and stayeth there until an Opportunity to void it out in his due time. The Spleen draweth from the Blood its terrestrial Part, viz. the Grounds, Lees, or thick Substance settled in the

bottom thereof, which you term *Melancholy*: The Bottle of the Gall subtracts from thence all the superfluous *Choler*; whence it is brought to another Shop or Workhouse to be yet better purified and fined, that is the Heart, which by its Agitation of *Diastolick* and *Systolick* Motions so neatly subtiliseth and inflames it, that in the *right side* Ventricle it is brought to Perfection, and through the Veins is sent to all the Members; each Parcel of the Body draws it then unto it's self, and after it's own Fashion is cherished and alimented by it: Feet, Hands, Thighs, Arms, Eyes, Ears, Back, Breast, yea, all; and then it is that who before were *Lenders*, now become *Debtors*. The Heart doth in it's *Left-side* Ventricle so thinnify the Blood that it thereby obtains the Name of *Spiritual*; which being sent through the *Arteries* to all the Members of the Body, serveth to warm and winnow or fan the other Blood which runneth through the Veins: The Lights never cease with it's Lappets and Bellows to cool and refresh it; in Acknowledgment of which good the Heart through the arterial Vein imparts unto it the choicest of it's Blood: At last it is made so fine and subtle within the *Rete Mirabile*, that thereafter those *Animal Spirits* are framed and composed of it; by means whereof the Imagination, Discourse, Judgment, Resolution, Deliberation, Ratiocination, and Memory, have their Rise, Actings, and Operations."

The above sentences clearly show that Rabelais had very definite ideas of the continuous processes of waste and repair, of absorption, assimilation and elimination, as they go on in the human body. Also that he had perfectly clear notions of the continuous movement of the blood, which was the sole vehicle of the requisite pabulum. So that, although he cannot be said to have made the motion of the blood precisely "circular," it cannot be denied that he has placed on record sufficient testimony to show that his physiological ideas were not so much behind those of William Harvey as most medical men of the present generation have, probably, been accustomed to think. Shakespearians and Baconians are not yet, I believe, quite agreed as to the extent of the acquaintance of the author of "*Coriolanus*" with the text of the fantastic work of Rabelais. But the ideas of those great authors on the subjects of digestion, nutrition, and the [(?) circulatory] movements of the blood undoubtedly display a curiously close degree of convergence. In a familiar scene of the great tragedy, the good old tale is introduced in which the stomach has to defend itself against the attacks of its envious neighbours:—

"'True is it, my incorporate friends,' quoth he,
'That I receive the general food at first,
Which you do live upon; and yet it is
Because I am the store-house and the shop
Of the whole body; but, if you do remember,
I send it through the veins of your blood,
Even to the court, the heart, to the seat o' the brain;
And through the cranks and offices of man,
The strongest nerves and small inferior veins
From me receive that natural competency
Whereby they live.'"

But the tracings of the pencil of genius have often been found to display closely similar curves, even when the guiding hands have been separated by an entire quadrant of the earth's circumference, and their inspired owners have been utterly unconscious of one another's existence!

I am, Sir, yours truly,

JOHN KNOTT, M.D.

34, York Street, Dublin, April 11th, 1902.

THE MANIPULATION OF MILK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Early-purification and refrigeration of town supplies of country milk is as great a human need as pure fresh air, sound meat, or wholesome bread; and the publication of Mr. Serin's letter is a valuable record, highly creditable to him and to your journal for publishing it. Nothing short of criminal ignorance largely prevails in connection with the English milk traffic. I write from personal knowledge and

experience of a most painful character. I can assure you that anyone who becomes connected with milk and its correct treatment is liable to suffer in both reputation and character. The very fact of the word "purification" hyphenated with the word "early," in the opening of these remarks, is a key that unlocks the door of gross ignorance, thoughtlessness, and absolute incapacity largely prevalent amongst those who are connected with English milk. I have been into hundreds of malodorous country cow-houses in England, teeming with filth, and the cow's bodies caked with dirt. I have often seen milk in London with lumps of dung in it, and inches of polluted sediment, so filthy was the condition it was sent off from the country in; while over and over again have I witnessed churns that have been emptied of their "fluid" covered towards the bottom with obnoxious adherent slime, and so forth. For years back have I urged upon dairy farmers and dairymen more care and cleanliness; I know, and warned them over and over again, that the prevailing state of things must end in exposure and reform; and I issued 35,000 pamphlets some years ago, pointing out the evil of toning down *fresh* whole milk by adding thereto *stale* separated milk, and so adding more fermentative (and much fermented) lactose or milk sugar, to the mixed milk; and thus creating a most dangerous and highly fermenting milk, sold as the genuine article. I had hundreds of other corroborative pamphlets also issued with tabulated records in it of 1,000 detailed analyses of milk samples taken under all sorts of conditions during nine consecutive months. But my experience is that I was powerless, in my practically almost single-handed fight, against ignorance and fraud.

It is bad enough for farmers to neglect early purification because of wrong feeding and dirty production, and early refrigeration because of natural liability to rapid decomposition and fermentation of milk, and particularly when warm with animal heat; but it is an aggravation of that serious-enough evil of omission when town dairymen mix into it more ferment by the addition of separated milk, and allow their employes to sell fermented milk as "nursery milk." It is a sin.

The whole business is, to a great extent, grossly wrong from beginning to end. If any of your readers wish for more enlightenment I will send on a "Dairy Catechism," if a stamped addressed envelope be sent me for the purpose. The perusal will be an exposure, and revelation to many.

I am, Sir, yours truly,
A. ROBINSON.

Crosby, 51, Thurlow Park Road, West Dulwich,
April 14th, 1902.

A NEW FORM OF SPLINTING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a general practitioner I have often felt the need that exists for some form of light, cheap splinting, easily cut when wanted into any desired shape and size, for it is practically impossible for a country or suburban general practitioner to keep ready-made splints in sufficient variety of shapes and sizes for all the various fractures he may at any time be called upon to treat. Gooch splinting is good and convenient, but many splints, such as right-angled ones, cannot be made from it. Poroplastic, also, is good, but rather heavy, expensive, and requires moulding.

Some time ago I made some splinting from corrugated boards, i.e., corrugated paper fastened between two sheets of cardboard. By fastening two such corrugated boards together with the corrugations in one at right angles to the corrugations in the other, I obtained a splinting which I have used for about a year. This splinting has the following advantages:—It is light; easily and quickly cut with a penknife into any desired shape; quite strong enough for any ordinary splint except a long hip splint; requires very little or no padding; transparent to X-rays, and very cheap.

Further, it may be strengthened as much as can possibly be desired, by the insertion of wires, such as bicycle spokes, into some of the corrugations, and in

right-angles splints some of the spokes will go one way in one set of corrugations and some at right angles on the other set of corrugations and in splints longer than bicycle spokes. The spokes can be inserted from each end overlapping in middle of the splint.

Also by cutting the splinting into the desired shape, then inserting a sufficient number of spokes or other wires this splinting can be then bent into many shapes suitable for orthopaedic purposes; for instance, I have used it successfully for splints for talipes plantaris to be worn at night instead of a Scarpa's shoe. The foot piece being forcibly bent round at right angles to the leg piece, and the angle can be easily strengthened by another such piece glued on to the outside. Tapes or elastics are easily fastened between the wires or spokes to hold down the toes in cases of hammer toes, &c.

The bicycle spokes, which are very strong and tough, are easily cut into desired lengths by a wire cutter, or simply nicked with a file and then broken off. For X-ray purposes these spokes can be withdrawn from all ordinary splints if desired without taking the splint off the limb and so again inserted. This splinting will not be so much required for stationary civil hospitals or by surgeons living near skilled instrument makers, but by army and other moving hospitals, ambulances, and by the great numbers of general practitioners living in the country or suburbs who have to make their own splints as required.

Messrs. Arnold and Sons have recently made some of this splinting covered with white paper cardboard, in sizes of thirty inches square, and they can also supply the bicycle spokes and spoke cutters.

I am, Sir, yours truly,
GEORGE B. BATTEN, M.D.

Dulwich.

Literature.

WALSH ON RONTGEN RAYS IN MEDICAL WORK. (a)

THERE is evidently room for a work which defines the application of these wonderful rays to medical and surgical practice, especially, perhaps, in respect of the former, where the information thus to be obtained is fully as useful as in the surgical department, although perhaps somewhat more difficult to elicit. The need for such a work as this is emphasised by the fact that we are already presented with a third edition—revised, in part re-written, and thoroughly brought up to date. Since its first appearance this book has secured and maintained its position as the standard English authority on Röntgen ray methods.

We gather that the improvements recently introduced into X-ray practice are mainly due to the increased power obtained from the induction coil by the use of mechanical breaks whereby clearness of definition is greatly enhanced, thanks to the increased power of penetration possessed by the rays thus reinforced. By means of an ingenious contrivance it is now possible to run both the mercurial break and the coil from the main, provided the current circulating therein be continuous. The improvements in the break have rendered unnecessary the use of the very large coils; in fact, a ten-inch coil, we are told, is now equal to all demands in this department of medical work. The coil still holds a foremost place in the special equipment for X-ray purposes.

In the present edition the introductory part has been written by Dr. Lewis Jones, chief of the electrical department at St. Bartholomew's Hospital, thus ensuring that the electrical section is abreast of the times. The purely medical and surgical aspects of the subject, in so far as they required to be modified, are dealt with in an appendix, and the finer quality of the more recent work is very obvious. The illustrations are numerous, and for the most part faithfully reproduced. Among them is a fine plate by the author of a case of military

"The Röntgen Rays in Medical Work." By David Walsh, M.D. Ed., Physician to the Western Skin Hospital, late Secretary to the Röntgen Society, London, &c. Third Edition. London: Baillière, Tindall and Cox. 1902. Price 12s. 6d. net.

tuberculosis, showing the individual tubercles, certainly the best of the kind we have seen.

Dr. Walsh was, we believe, the first to systematise the study of these rays, in their medical uses, in the English language, and we may congratulate him upon the satisfactory manner in which he has accomplished the task.

The work is beautifully printed and solidly bound, and reflects credit on the publishers.

HADLEY ON NURSING. (a)

THIS little book is designed to afford nurses some general knowledge of the various diseases, medical and surgical, which they are likely to meet with, and at the same time give them some instructions as to the different duties which they may be called on to perform in connection with them. It is not an easy matter to say how far a nurse should be instructed in the nature of the different diseases which she may be called on to attend. If she is taught too much there is a danger of her forgetting that she has merely to nurse her patient under the instruction of the medical attendant, while if she is taught nothing of the reasons for what she is told to do there is the greater danger of her becoming a mere machine, and a machine, too, which is very likely to break down in the carrying out of some essential, but apparently trivial, detail. Dr. Hadley has, we think, hit the happy mean in this book, and his description of the various diseases, both medical and surgical, is admirable, both in clearness and brevity, and in this connection there is little or nothing that could with benefit be omitted from the book. In some of his directions however, as to how this knowledge is to be applied he is not so happy. It seems a pity that in a book like this such a special subject as midwifery nursing should be included, and we doubt very much if the instruction given on this subject will meet with the approval of obstetric physicians. What, for instance, would be said to a nurse who adopted the following procedure recommended in the treatment of the third stage of labour. "If after twenty minutes there are no pains or they are ineffectual in expelling the placenta it should be expressed. To do this, press the uterus downwards and backwards with the left hand while feeling for the placenta with the right hand in the vagina. When it is received in the right, twist it round and round so as to make a sort of rope of the attached membranes and so facilitate their complete removal."

There is also a lack of clearness in dealing with the aseptic and antiseptic methods of surgery which is liable to puzzle a nurse. For example, we are told that "dry gauze dressings may be simply rendered antiseptic by subjecting them to great heat in a suitable steriliser, or they may be impregnated with various antiseptics." Here the information is misleading, and even were it correctly understood it is of little use since it affords the nurse no idea how practically to sterilise such gauze. In spite of these defects, however, the book will, we feel sure, be found most useful to nurses, and will greatly assist them in intelligently carrying out those instructions which so materially affect the comfort and well-being of the patient.

BUTLIN ON THE OPERATIVE SURGERY OF MALIGNANT DISEASE (b).

IT is twelve years ago since the first edition of this invaluable work was issued, and as the changes in surgery since 1887 have been very great, some chapters have been rewritten, and there is scarcely one of them which has not required considerable alteration. The author has also had the help of several surgeons familiar with cancer of special parts of

the body, so that the work may justly claim to be an up-to-date and faithful reflection of the relation of surgery to cancer.

The work is intended to indicate the class of cases and the parts of the body which may be treated by operative means with the best prospect of success; to encourage the performance of operations in suitable cases at the earliest period; to discourage the repetition of useless operations; to indicate the extent of removal which is required for the treatment of the different varieties of cancer in the different parts of the body.

The author's contention that the more closely the patients are followed up, so much the better are the final results, continued observation has proved. Compared to what it was the reduction of the immediate mortality of almost all operations is very striking. It is much less in amputations, but the same in operations on the jaw as it was in 1887. Mr. Butlin insists that the very large majority of cancers of the tongue commence in the form of a compound wart or warty growth. Amputation at the hip-joint for subperiosteal sarcoma offers really no prospect of cure. The importance of parotid tumours is insisted upon, because they are endotheliomas of the lymphatics, and though often undoubtedly malignant they may be innocent. Facial palsy is generally a sign of malignancy, and the surgeon must not scruple to cut the nerve if complete removal requires it. In cancer of the face in old people great care must be taken to avoid loss of blood, and in dressing to give an anæsthetic or to inject morphia. Epithelioma of the antrum is often mistaken for necrosis from the pain and suppurating sinuses, the lymphatic glands are only rarely affected. In all operations on the tongue, tonsil, and upper jaw, the author recommends the lateral posture, early clamping of the vessels, plugging the wound with gauze, free dependent drainage, frequent dressings, and feeding through a tube. He is not in the habit of opening the neck simply for the purpose of ligaturing the carotids or lingual arteries. When he does ligature the lingual, it is just where it comes off from the external carotid. In cancer of the tongue the submaxillary and cervical glands are most likely to be affected, the submental also when the disease is at the tip, and the parotid glands when near the root. The author's doctrine is, whenever it is possible, operate at once.

Innocent endotheliomas may quite easily be shelled out of the palate in a few seconds by an incision along the anterior margin of the tumour. The work abounds in practical hints of the greatest value both to the general practitioner and to the operating surgeon. Slight errors in the text are to be found on pages 257, 267, 287, 366 and 389.

ROTCH'S MANUAL OF PEDIATRICS. (a)

THE great advances, which have been made in the subject of pediatrics, have rendered it necessary that Professor Rotch, in preparing the third edition of his excellent work, should almost entirely re-write it. In so doing, he has endeavoured to accentuate the practical character of his work, and to more thoroughly systematise the descriptions of the various diseases. Special attention has been paid to the advances in the hygiene and dietetics of early life, while a considerable number of fresh plates, and some excellent radiographs, have been added.

The opening divisions of the book deal with normal development and the feeding of infants, and appear to us to be particularly valuable. Dr. Rotch enters very fully into the physiology of the fœtus, and furnishes some admirable tables of the various measurements of the fœtus, the weight of the latter and of its various viscera, and much other similar statistical matter. The chapter on Infant Feeding also contains many such tables, and, indeed, those to which we have drawn attention, as well as many others, constitute an important feature of the work. The third division of the book

(a) "Pediatrics, the Hygienic and Medical Treatment of Children," By Thomas M. Morgan Rotch, M.D., Professor of the Diseases of Children, Harvard University. Third edition, re-arranged and re-written. Pp. XXI. and 1,021, with numerous Engravings and Coloured Plates. Philadelphia: Lippincott and Co. 1901.

(a) "Nursing: General, Medical, and Surgical, with an Appendix on Sick-Room Cookery." By Wilfred J. Hadley, M.D., F.R.C.P., Physician and Pathologist to the London Hospital. London: J. and A. Churchill. 1902. Price 3s. 6d.

(b) "On the Operative Surgery of Malignant Disease." By H. T. Butlin, F.R.C.S., D.C.L., Surgeon to St. Bartholomew's Hospital & Co., with the co-operation of James Berry (the Throat), W. Bruce Clark (the Kidney), Allan Doran (the Ovary and Uterus), Percy Furnival (the Stomach, Intestine and Rectum), Walter Jessop (the Eye), H. J. Waring (the Liver and Gall-Bladder). Second Edition. London: J. and A. Churchill, 1900.

is devoted to the general principles of examination and treatment of children, and contains a short paragraph on the use of the X-rays in diagnosis. Among the radiographs which are reproduced may be mentioned several which show the changes that take place in rachitis, tuberculosis, osteo-myelitis and syphilis, and also the changes in the various abdominal organs. The remaining divisions include the diseases of the skin, specific infectious diseases, diseases of special regions and viscera, and diseases of the nervous system, all of which attain a very high standard of excellence.

Dr. Rotch's work is obviously too long to review in detail. We must content ourselves by saying that we consider it to be a trustworthy and readable work which, from its scientific character and the amount of information it contains, will be found to admirably meet the requirements of medical men, whose practice, either as specialists or as general practitioners, necessitates a careful study of that most engrossing subject—the diseases of children.

DISORDERS OF ASSIMILATION, Etc. (a)

It seems a pity that the author did not choose a title more distinct from that of his previous work, entitled "Disorders of Digestion." It is true he points out in the preface that this is not a second and enlarged edition of the other, but still we fear that many, not seeing this statement, would naturally consider that it was.

The book is made up of "a collection of scattered papers and addresses, written at various times, and delivered on various occasions." As may be expected, then, some will be found entirely technical, unadapted to the non-medical reader, whereas many of the educated public might derive great benefit from a study of the chapter on "Stimulants and Narcotics," if they applied some of its teachings to themselves.

In that chapter, however, we would take exception to the dictum (p. 141) that the drunkard transmits the craving for alcohol to his offspring. It seems a most disastrous idea to get abroad, as it is liable to seriously lessen the already lowered self-control of such unfortunate offspring. If a young man, the son of an intemperate father, has a learned authority to support his saying "I can't help," when he finds himself thrown in the way of temptation, he may soon be expected to add "and I don't care" to his hopeless position.

It is surely very exceptional to find among morphinists (p. 156) that "authorities . . . bearing names of the highest reputation, are subject to this craving, *without the least detriment to their capacities.*" (italics ours). Concerning the treatment of the morphia habit, we read (p. 156), "according to Dr. Levenstein it is best to deprive them at once and completely of morphia instead of gradually withdrawing it." But Dr. Levenstein added that they most frequently became violent and suicidal, and out of a large number only 25 per cent. recovered. Hence such a method of treatment, now-a-days, is rather old-fashioned, not to say unsatisfactory and even dangerous.

For the medical man who wishes to improve a leisure hour the book is well worthy of his attention. He will there brush up his physiology and therapeutics in well-written, interesting chapters, these subjects being brought into practical contact with the real subject matters of everyday medicine, and are thus deprived of the dry technicalities which repel the practitioner and make him hesitate to apply to his text books for an explanation of the phenomena he may meet with in his daily practice. The chapters are written in an attractive form, and with the thoroughly scientific spirit of the author, make a valuable addition to the library of the practising physician.

OUR Berlin correspondent reports the death of Professor Hans Buchner, the eminent hygienist and bacteriologist of Munich University, who died at Munich on April 5th, aged 52.

DISEASES AND INJURIES OF THE TEETH. (a)

THIS work is not adapted for the medical reader who needs only to gain a knowledge of dental disease at the points where it touches upon practical medicine and surgery. The book is too big, too diffuse, and too obscure in style for that class of reader, or indeed, for anyone not already well acquainted with the fundamental facts and theories of dental science. The book may, however, be strongly recommended to senior dental students preparing for examination. The number of works of this kind is very limited, and if the dental student provides himself with all of these and masters their contents he will not have made a serious draft upon an average purse nor inflicted an undue strain upon an average intellectual endowment. The work contains a large number of first-rate illustrations which alone would make it valuable to the dental reader; whilst a good many points not mentioned or not so fully discussed in other books of the kind, are to be found scattered through its pages. The cardinal defect in the work lies in the quality of the writing. The writing all through lacks the quality of objectivity. Passages constantly present themselves the meaning of which is evident to anyone who has already mastered the essential knowledge of the subject, but which would be either totally incomprehensible to, or liable to serious misconstruction by, those only entering upon a study of dental surgery. It is only fair to say that this edition shows a great advance on the first in the matter of literary quality, much as it may still be below the proper level. It would be easy to cite from almost every page passages to illustrate our meaning, and we are sure that if Mr. Colyer will submit his pages to any competent literary adviser, he will become convinced of the necessity for thorough revision in this regard before another edition is prepared. The skilled dental reader having enough knowledge is in most cases able to guess with certainty the meaning of doubtful sentences. The book needs revision mainly from the point of view of composition alone, and this would be best done by someone unlearned in dental science. Authors of works of this kind are not called upon for eloquent or florid language; but they are bound to have mastered the art of making their meaning absolutely clear. This is an art which, unless the writer have a literary gift, can only be acquired by long and patient labour; but until it is mastered it is impossible to produce a work which will pass with approbation the examination of the least conscientious of reviewers.

NEW BOOKS AND NEW EDITIONS.

THE following books have been received since the publication of our last monthly list:—

BAILLIÈRE, TINDALL and COX (London and Dublin).

The Estivo-Autumnal Malarial Fevers. By Chas. F. Craig, M.D. With coloured plates and charts. Pp. 221. Price 10s. 6d.

The Dynamic Aspects of Nutrition and Heredity. By Frank Horridge. Pp. 102. Price 5s.

The Röntgen Rays in Medical and Surgical Work. By David Walsh, M.D. With Section dealing with Electrical Methods and Apparatus. By Lewis Jones, M.D., F.R.C.P. With numerous plates. Third Edition. Price 12s. 6d.

Acute Dilatation of the Stomach. By H. Campbell Thomson, M.D. Lond., M.B.C.P. Pp. 64, with plate. Price 3s.

Retinoscopy after the Method of Cuiquet. By Edward Harding London, M.A., M.D. Two vols. Atlas and Text. Price 10s. 6d.

Traité de Médecine et de Thérapeutique, Publié sur la direction de MM. les Professeurs Brouardel et Gilbert. Vol. ix. Pp. 1,004, avec 173 figures. Prix 12 frs.

J. and A. CHURCHILL (London).

A Manual of Practical Anatomy. By the late Prof. Alfred W. Hughes, M.D., M.C., F.R.C.S. Ed. Part II, edited and compiled by Arthur Keith, M.D., F.R.C.S. Pp. 308. Price 8s. 6d.

CORNISH BROTHERS (Birmingham).

Contributions to Practical Medicine. By Sir Jas. Sawyer, M.D., F.R.C.P. Third Edition. Pp. 209.

CROSBY, LOCKWOOD, and CO. (London).

The Health Officers' Pocket Book. By Edward F. Willoughby, M.D. Lond. Pp. 424. Price 10s. 6d.

(a) "Diseases and Injuries of the Teeth." By Morton Smales, M.B.C.S., L.S.A., L.D.S., and J. F. Colyer, L.R.C.P., M.B.C.S., L.D.S. Second Edition revised and enlarged by J. F. Colyer. London: Longmans, Green and Co. 1901. Price 21s.

CHAS. GRIFFIN AND CO., LIMITED (London).

Forensic Medicine and Toxicology. By J. Dixon Mann, M.D., F.R.C.P. Third Edition. Pp 692. Price 21s.

H. K. LEWIS (London).

A Concise History of Small-pox and Vaccination in Europe. By Ed. J. Edwards, M.D., Lond. Pp. 142. Price 2s. 6d.
Selected Essays and Monographs from English Sources: Braxton Hicks, Bodington, Hodgkin, Paget, Humphrey, Ehlers, London: the New Sydenham Society. 1901. Pages vii. and 325.

J. B. LIPPINCOTT COMPANY (Philadelphia and London).

Photographic Atlas of Diseases of the Skin. By Geo. Hy. Fox, A.M., M.D. Part xiii. to xvi., completion of work.

LONGMANS, GREEN AND CO. (London).

Selected Essays and Addresses. By the late Sir James Paget, Bart., F.R.C.S., F.R.S. Edited by Stephen Paget, F.R.C.S. Pp. 445. Price 12s. 6d.

Malarial Fever: its Cause, Prevention and Treatment. By Ronald Ross, F.R.C.S., F.R.S. Ninth Edition. Pp. 68. Price 2s. 6d.

MACMILLAN AND CO., LIMITED (London).

Some Thoughts on the Principles of Local Treatment in Diseases of the Upper Air Passages. By Sir Felix Semon, M.D., F.R.C.P.

The Climates and Baths of Great Britain. Vol. II. Report of Committee of the Royal Medico-Chir. Society of London. Price 12s. 6d. net.

The Treatment of Injuries by Friction and Movement. By Wharton P. Hood, M.D., M.R.C.S. Pp. 182. Price 4s. 6d.

THE MACMILLAN COMPANY (New York).

The Rontgen Rays in Medicine and Surgery. By Francis H. Williams, M.D. Harv. Pp. 658. Price 25s. net.

YOUNG J. PESTLAND (Edinburgh and London).

The Study of the Pulse and of the Movement of the Heart. By James Mackenzie, M.D. Edin. Pp. 325.

Handbook of Obstetric Nursing. By F. W. N. Haultain, M.D., and James H. Ferguson, M.D. Pp. 287.

THE SANITARY PUBLISHING COMPANY (London).

The Prevention of Infection in Public Vehicles. By Alfred Greenwood, M.D., D.P.H. Pp. 65. Price 1s.

Practical Smoke Prevention. By William Nicholson. Pp. 151. Price 3s. 6d.

SMITH, ELDER AND CO. (London).

St. Bartholomew's Hospital Reports. Vol. xxxvii. 1901. Edited by Norman Moore, M.D., and D'Arcy Power, F.R.C.S. Price 8s. 6d.

SPOTTISWOODE AND CO., LIMITED (London).

The Medical Register for 1902.

The Dentists' Register for 1902.

Issued under the authority of the General Medical Council.

SWAN SONNENSCHEIN AND CO., LIMITED (London).

A Text-book of Insanity. By Chas. Mercier, M.R.C.P., F.R.C.S. Pp. 222.

ALEX THOM AND CO. (Dublin).

Calendar of the Royal University of Dublin for the Year 1902.

JOHN WRIGHT AND CO., (Bristol).

The Medical Annual: A Year-book of Treatment. By Various Contributors. Pp. 774. Price 7s. 6d.

An Introduction to Dermatology. By Norman Walker, M.D., F.R.C.S. Ed. Pp. 301. Price 9s. 6d.

Medical News.

Death under Chloroform.

A WOMAN who was undergoing an operation for pelvic abscess at the Swansea Hospital died while still under the influence of the anæsthetic one day last week, but a post-mortem examination revealed the fact that death was due to cardiac embolism consequent upon the depressed condition of the circulation. A man, aged 28, died under chloroform at the Newcastle Royal Infirmary a few days since, although he had taken the anæsthetic well on a previous occasion. The autopsy showed that he was the subject of marked visceral disease associated with considerable cardiac hypertrophy. The usual verdict was returned.

Death from Morphia.

An inquest was held on the 6th inst. at Kelloe on the body of James Macalman Fraser, M.B. Ed., who had succumbed to the effects of an overdose of morphia, leaving a letter which seemed to point to suicide, a question which the jury declined to decide, and therefore left open. Dr. Fraser was a native of Nova Scotia, and was only 28 years of age.

The Plague.

DURING the twelve months ending on April 7th there have been 382 cases of plague in Egypt, of which 228 have terminated fatally, 137 have been cured, and 17 are still under treatment. Two hundred and six of the deaths occurred in the Delta and 13 in Upper Egypt. No case has occurred in Cairo.

Medical Press Conference.

THE International Conference of the Medical Press opened at Monaco on the 8th inst. The object of the conference is the establishment of an international Medical Press Syndicate.

Action Against a Dentist for Malpraxis.

MR. J. C. OLIVER, of Cardiff, was the defendant in an action tried at the Glamorganshire Assizes, last week, in which damages were claimed against him for unskilful extraction of a tooth. It seems that as a preliminary step to fitting a denture he had occasion to extract a canine tooth which had only made its appearance six months previously. In the attempt to extract the tooth it was pushed through the upper maxilla and apparently pierced the inner wall of the antrum, injuring the cartilage of the nose. This was not known to the patient at the time, but she suffered severely after the operation and, later, her attention was called to the history of a case published by the defendant in the *Dentists' Journal*, which she applied to herself. The accident appears to be rare, if not indeed quite unique, and there was abundant evidence to show that its occurrence did not imply any negligence or want of skill, and the jury returned a verdict for the defendant. This trying experience is calculated to render operators chary of publishing their usual experiences even in the technical journals, which is a pity, because their educational value is very great.

Is Self-Vaccination Chargeable?

DR. HUNTER, public vaccinator for Stow, vaccinated himself in his drawing-room and charged the guardians for a vaccination "at the residence." The guardians strained at the gnat, and the Local Government Board will be called upon to decide whether Dr. Hunter *qua* public vaccinator is entitled to recover a fee for vaccinating Dr. Hunter *qua* citizen and ratepayer. It is a pretty quarrel, and argues either a very litigious spirit or an exaggerated sense of humour on Dr. Hunter's part. He has at any rate achieved a *succes de notoriété*.

Society for Relief of Widows and Orphans of Medical Men

At the Quarterly Court of this society, held on Wednesday last, the President, Mr. Christopher Heath, F.R.C.S., in the chair. Seven new members were elected and the deaths of four members reported. Applications for the renewal of grants were read from fifty-two widows, eleven orphans, and five recipients from the Copeland Fund, and a sum of £1,282 was voted to be given at the next Court. Two fresh applications from widows were read and grants made. Donations amounting to £221 15s., including £200 from the Exors. of Miss C. A. Birch, were announced. The annual general meeting will be held on May 21st at 5 p.m. The report for 1901 was read. Nine members were nominated for election at the annual general meeting to fill the vacancies in the Court of Directors. The expenses of the quarter were £58 5s.

Dublin Death Rate.

The deaths registered in the Dublin registration area for the week ending Saturday, April 5th, 1902, represent an annual mortality of 27.9 in every 1,000 of the population. Diseases of the respiratory system caused 49 deaths, and diseases of the circulatory system 31 deaths. In 12 instances the cause of death was uncertified, there having been no medical attendant during the last sickness; 49 of the persons whose deaths were registered were infants, of whom 28 were under one year old, and six were under one month old. The death-rate in the following districts—Blackhall Place, Castle Street, was 31.3, 30.5, and 33.7 respectively.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MRS. E. J. FIELDER's communication is evidence of what we expected.

DR. E. A. SAUNDERS.—We are unable to publish the report of the meeting just received, on account of its having been held over for so long a time.

MR. HENRY JOHNSON.—No intimation of the kind has reached us and in any case the matter is hardly one in which we should care to take the initiative.

K. R. N.—You had better apply direct to the Secretary of the Institution.

THE LUXURY OF DOOR-PLATES.

Brass-plates on the doors of houses occupied by medical men appear to offer an attraction to a certain class of thieves that they are unable to resist. Recently two youths of the ne'er-do-well class, were sentenced by the Lambeth magistrates to two months hard labour for having several doctors' plates in their possession which they were trying to "sell." We have also heard of a medical man who having lost three plates in as many months, has substituted a zinc door-plate, which needless to say, remains where he had it placed.

T. J. C.—The best and most practical of the small books on the subject with which we are acquainted, is the "Aids to Diagnosis and Treatment of Diseases of Children," by Dr. McCaw, 3s. 6d. Of the larger books "Diseases of Children" by Drs. Ashby and Wright can be recommended. Price 25s.

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, APRIL 16TH.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—7.30 p.m.

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Great George Street, Westminster, S.W.).—7.30 p.m.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover Square, W.).—8.30 p.m. Discussion adjourned from the last meeting on Chronic Affections of the Kidney, and Morbid Conditions of the Urine arising therefrom, in Relation to Balneological, Climatic, and Dietetic Treatment.

FRIDAY, APRIL 18TH.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos Street, Cavendish Square, W.).—5.30 p.m. Cases by Dr. Edmund Cantley, Mr. Sydney Stephenson, and Dr. Dan McKenzie. Specimens by Dr. J. H. Thomson Walker. Papers—Mr. E. H. A. White-locke (Oxford): Notes on a Case of Double Inguinal Hernia in a Female Child, each Sac containing an Ovary-like Organ. Dr. G. Carpenter: A Case of Malignant Endocarditis which developed Optic Papillitis, Sub-retinal Hemorrhages, and Simulated Choroidal Tubercle, and other Changes in the Fundus Oculi.

DUBLIN.

THURSDAY, APRIL 17TH.

ROYAL COLLEGE OF SURGEONS.—Council Meeting.

FRIDAY, APRIL 18TH.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Obstetrics, Royal College of Physicians.—8.30 p.m. Specimens:—Dr. Purefoy: Large Fibroid Polypus Uteri; Hematosalpinx and Ovarian Cyst; Fibroid Uterus removed by Panhysterectomy. Dr. Alfred Smith: A Uterus with Broad Ligaments Removed for Cancer; Double Pyosalpinx. Dr. E. H. Tweedy: Large Myoma Removed by Abdominal Hysterectomy. Discussion on Dr. Purefoy's Report of the Rotunda Hospital for 1900-01. Paper:—Dr. E. H. Tweedy: Observations on the First Stage of Labour. The Causal Relation of this Stage to Rupture of the Uterus.

MONDAY, APRIL 21ST.

CONJOINT ROYAL COLLEGES.—Third Professional Examination.

Appointments.

BENNETT, C. J., M.R.C.S., Medical Officer of Health to the Chapel-en-le-Frith Rural District Council.

BURTON, H., L.R.C.P.Irel., M.R.C.S., Medical Officer of Health to the Marple District Council.

BYTHILL, W. J. S., B.A., M.B., Ch.B., Junior Anaesthetist to the Manchester Royal Infirmary.

CLAPHAM, LUCY B., M.B.Lond., Obstetric Physician to the New Hospital for Women, Euston Road, and Assistant Anaesthetist to the Royal Free Hospital.

COPE, RICARDO, M.R.C.S., L.R.C.P.Lond., House Surgeon to the Dorset County Hospital, Dorchester.

GREENWOOD, G. S., M.R.C.S., L.R.C.P.Lond., Medical Officer of Health to the Oset Corporation.

HARMAN, N. BISHOP, M.A., M.B.Cantab., F.R.C.S.Eng., Ophthalmic Surgeon to the Belgrave Hospital for Children.

HARRETT, CHARLES, J., M.D., L.R.C.P.Lond., M.R.C.S., Honorary Assistant Visiting Surgeon to the Royal Sea Bathing Hospital, Margate.

HODGSON, R. E., M.R.C.S., L.R.C.P.Lond., Senior Resident Surgeon to the Royal Sea Bathing Hospital, Margate.

JEFFERY, H. FOSTER, M.B., Ch.B. Vict., Honorary Surgeon to the Bury Infirmary and Police Surgeon for Heywood.

KEMPE, C. M., M.R.C.S., L.S.A., Medical Officer of Health to the Shoreham Urban District Council.

LISTON, MARY F., M.B., B.S.Glaag., Junior Assistant Medical Officer to the Govan Parish Council.

MARSHALL, FRANK E., M.B., Ch.B. Vict., L.S.A., Honorary Surgeon to the St. George's Hospital for Diseases of the Skin, Liverpool.

PRICE, PERCIVAL UNDERDOWN, M.R.C.S., L.R.C.P.Lond., Medical Officer to the Destitute and Aborigines in the district of Penak, South Australia.

Vacancies.

Borough of Durban, Natal, South Africa.—Medical Officer of Health. Salary £750 per annum. Applications to Messrs. Webster, Steel, and Co., 5, East India Avenue, Leadenhall Street, London, E.C.

Bradford Royal Infirmary.—Dispensary Surgeon. Salary £100 per annum, with board and residence. Applications to William Maw Secretary.

Catholic University of Ireland.—Several Vacancies for Lectureships and Assistant Professorships. Immediate applications to the Registrar Medical School, Cecilia Street, Dublin. (See Advt.)

Central London Sick Asylum District.—Election of Assistant Medical Officer. Salary £120 per annum, with board and residence. Applications to Fred. W. Bailey, Clerk's Office, Cleveland Street Asylum, Cleveland Street, London, W.

City of Nottingham, Parish Infirmary.—Assistant Medical Officer. Salary £160 per annum and furnished rooms. Applications to the Clerk to the Guardians, Poor-law Offices, Shakespeare Street, Nottingham.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer Unmarried. Salary £120, board, furnished apartments, &c. Applications to the Medical Superintendent.

London County Asylum, Horton, near Epsom, Surrey.—Dispensary. Salary £110 per annum. Applications immediately to R. W. Partridge, Clerk of the Asylums Committee, Office, 6, Waterloo Place, S.W. (See Advt.)

London County Asylum, Horton, near Epsom, Surrey.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Applications immediately to R. W. Partridge, Clerk of the Asylums Committee, Office, 6, Waterloo Place, S.W.

Reinhill County Asylum, near Liverpool.—Assistant Medical Officer. Salary £150 per annum, furnished apartments, board, attendance and washing. Applications to the Medical Superintendent West Norfolk and Lynn Hospital, King's Lynn. House Surgeon. Salary £100 per annum with board, residence, and washing. Applications to the Chairman of the Weekly Board.

Births.

HARRISON.—On April 5th, at 320, Humberstone Road, Leicester, the wife of L. K. Harrison, M.B. Camb., of a son.

HOARE.—On April 8th, at Harlow, Essex, the wife of G. de M. G. Hoare, of a son.

HOLDEN.—On April 8th, at Castle Hill, Reading, the wife of George Herbert Rose Holden, M.A., M.D. Cantab., of a son.

HOVENDEN.—On April 7th, at Kitson Lodge, Barnes, S.W., the wife of Gerald S. Hovenden, M.D., B.S.Lond., M.R.C.S., of a daughter.

LANGDON-DOWN.—On April 8th, at Rudder Grange, Hampton Wick, the wife of Percival L. Langdon-Down, M.B., B.C., of a daughter.

O'CONNOR.—On April 9th, at The Hollies, Llanymynech, the wife of H. S. O'Conor, L.R.C.P.S., of a son.

SMELT.—On April 10th, at 371, Holloway Road, Islington, N., the wife of C. A. Casterton Smelt, M.B., C.M., E. lin., of a son.

Marriages.

DENING—RICHARDSON.—On April 9th, at St. Mary Abbot's Church, Kensington, Edwin Dening, M.R.C.S., L.R.C.P., The Manor House, Stow-on-the-Wold, to Florence Beatrice, eldest daughter of G. Richardson, 64, Lexham Gardens, Kensington, W.

MANLOVE—EVERETT.—On April 12th, at St. Stephen's Church, South Dulwich, Jas. Ernest Manlove, M.R.C.S., of Hastings, younger son of the late J. Dixon Manlove, of Nottingham, to Margaret, only daughter of Ed. M. Everett, of Dulwich Common.

MENNEL—LEWIS.—On April 10th, at St. Mary Abbot's Church, Kensington, Zebulon Mennell, M.B.Lond., eldest son of Mr. Zebulon Mennell, of 1, Royal Crescent, W., to Fanny Mabel, only daughter of the late Mr. Arnold Lewis, barrister-at-law, and Mrs. Arnold Lewis, of 29, Elham Road, London, W.

WALKER—ELWELL.—On April 9th, at the Parish Church, Llanllwchaearn, Newtown North Wales, David Faris Walker, M.D., of Portlaw, County Waterford, to Caroline Eaton Elwell, of Neyoddfrith, Newtown, North Wales.

Deaths.

NEURASTHENIA.

By ROBERT S. BOWLES, M.D., F.R.C.P.,
Consulting Physician to the Folkestone Hospital, &c.

THE absence of definite pathological changes in cases of neurasthenia and many neurotic diseases, and the gravity and variety of their symptoms have caused me to study with care the practical influence of the nervous system upon functional as opposed to definite and specific diseases. What we understand in medicine by function is in the main a performance, an action of an organ or set of organs or of different tissues; any act necessary for accomplishing a vital process.

Anatomy shows us that the whole arterial system, and the heart and veins also, are almost entirely supplied with nerve influence by the sympathetic nervous system, those soft, pink, insignificant looking masses lying in front of the vertebræ, which go to form, with branches from spinal and cranial nerves, the great thoracic, abdominal, and hypogastric plexuses, and the following well-known experiment demonstrates very clearly in what way the normal conditions of the vessels, organs and tissues supplied by that system may be changed and their functions profoundly affected.

If the cervical sympathetic in a rabbit be divided, the blood vessels of the corresponding side of the head and neck become dilated. The effect is best seen in the ear, the blood vessels of which become manifestly larger than those of the opposite side, while the part becomes both redder and warmer from the increased blood supply. On stimulating the peripheral end of the divided nerve the vessels are seen to contract again, and, as long as the stimulus lasts, the parts become paler, colder, and less sensitive than natural. Thus the normal or permanent contraction of the arteries is evidently due to the influence of the nervous stimulation of the muscular coats, and when this is withdrawn, as by division of the nerve, the vessels dilate.

There are many illustrations of partial and temporary dilatations of arteries which will occur to your minds, and which in the course of practice you will have seen and investigated; for example, the great dilatation which is observed in the large vessels after active and violent exertion, the pulsating dilatation of the abdominal aorta in neurotic subjects, so suggestive in our early practice of abdominal aneurysm, pulsating dilatation of the carotids in anæmic subjects, of the superficial temporal of one or other side in headaches and neuralgia, and in the large vessel leading to an inflamed area. The venous system is liable to similar partial and temporary fluctuations and so, we all know, is the heart also.

It is important that we should fully realize these facts, for facts they are, and facts which help us in

solving the many strange and puzzling phenomena which daily and hourly come before us, and which, in a large proportion of cases, we are justified in looking upon as *functional* and capable of being cured. It is too much the custom of the present sceptical age to shy at the word cured, but if we can by our remedies change the conditions of derangement of functions and relieve the existing suffering, I see no reason to belittle our work or to be afraid of claiming credit for it, and saying we cured the patient, it is encouraging to us in our future work and most satisfactory to the sufferer.

A medical man, of about 35 years of age, complained of stiffness and pain down one side of his neck. He found the part distinctly tender, and on looking in the glass he observed a powerful pulsation and apparently considerable enlargement of the left carotid artery. A friend saw it and confirmed the fact that the carotid was distinctly enlarged, tender and powerfully pulsating, and that the increased pulsation was definitely localised to the seat of pain and tenderness. The patient had not long before suffered from a mild but definite attack of gout, and the day before had been fatigued by a day's hunting and been chilled by a cold blast, whilst waiting at the edge of a covert. The symptoms lasted a week or ten days and then gradually subsided.

A few years later a similar but less severe attack occurred, and from time to time during gouty threatenings the carotid artery of that side was often threatening also.

A Colonel of Engineers consulted me for a pain down his right arm and curious sensations in the hand. On tracking the pain upwards I detected a strong pulsating prominence just behind the clavicle, which proved on careful examination to be a local dilatation of the subclavian artery. It was tender to the touch; there was no apparent cause for it, but there could be no doubt about its nature. The pain in the arm gradually diminished, and the swelling too. I sent him to see Mr. Holmes, who said the enlargement was not then sufficiently marked to make the case clear. The patient lived fifteen years or so after, and died somewhat suddenly from what was supposed to be heart disease. There was no sign of heart disease when he was under my care.

It is quite impossible to trust to the opinion of the patient as to the nature of his illness.

About two months ago an Irish gentleman called upon me complaining of an attack of gout in the foot, which he had inflamed by rubbing in Elliman's embrocation. On uncovering his foot I at once saw that the appearances did not conform to those of ordinary gout; the foot was swelled, but not after the manner of gout, and the redness was of a darker and somewhat dusky colour, the nature of the pain, too, was different and the sensibility quite different; indeed, on cross-examination he admitted

that there were numbness and coldness, and that sensation to touch was very much diminished, indeed, on some parts of the inner side quite absent; pulsation in the posterior tibial artery could not be detected, and the pulse in the dorsal artery of the foot was extremely small; there was nothing abnormal to be found in the popliteal space. In the upper femoral region it was altogether different, in the groin and above Poupart's ligament the artery was hard, large, rigid, resistant, prominent and somewhat tender on pressure. I sent him home to rest and apply cotton wool, and insisted on the avoidance of all unnecessary movements of the limb.

Three or four days later, and against my instructions, he returned to me saying that he was better and thought a little movement would do him good. I found the foot looking better, less swelled, and better in colour; the posterior tibial pulse below the malleolus had returned, and was normal, but there was now no pulse to be felt in the dorsal artery of the foot, and numbness and loss of sensation accompanied the distribution of that vessel.

On further inquiry I ascertained that he wore a truss, that he wore it, too, more on the prominent artery than over the inguinal canal, that the truss sometimes hurts him, and that he bicycled. Here, then, was the probable explanation of the case—a dislocation of some friable portions of the inner coat of the artery, a drifting of that portion into the popliteal, blocking at first more or less both its divisions, and finally settling in and entirely blocking the anterior vessel. My patient gradually improved, but I heard of his doing unwise things immediately on his return home.

Patients often present themselves for treatment for sciatica who, on inquiry, clearly are not suffering from that disease. They have pains down the leg, it may be outside and inside and down the front of the thigh, but not at the back or anywhere in the course or distribution of the sciatic nerve. In such cases it is always necessary not only to investigate the condition of the pelvic organs but also carefully to examine the state of the large vessels above and below Poupart's ligament. I call to mind many such cases, and have, I feel sure, been of use not only in making the patients understand their condition and so safeguarding them from future dangers, but also in resting and soothing the tender vessels and so relieving present pains and local swellings. In many cases of advancing age, and especially in gouty people, the vessels will be found to be atheromatous and to vary in size from time to time.

A gentleman, *et. 75*, who had suffered many attacks of true gout, complained of pain and tenderness in the upper femoral region, and finding a lump there he was much alarmed, and was convinced that he was the subject of a strangulated hernia. The lump was there plain enough, and so was the pain and tenderness, but it was a *pulsating* lump, and the vessels were hard and resistant. With rest, mild aperients and an anti-gout regimen the pains and tenderness faded away, and in a few days the swollen vessels had palpably diminished in size and the pulsation had much diminished in force.

A lady who had long been treated for sciatica, which she assured me was her malady, had iliac and femoral vessels which were quite hard, dilated and tender, and, on close questioning, she admitted that her pains were more down the front and inner side of the thigh, and not in the course of the sciatic nerve. This lady gradually lost muscular power in the legs, and in the course of years her mind became weakened, I assumed, from a gradual extension of the atheroma to other and more important parts. I have seen several trying cases of loss of muscular power and restricted movement associated with such a condition of vessels, and

which have been supposed to arise from chronic rheumatic arthritis. This lady's vessels distinctly varied in size at different times, according to the state of her health and other circumstances; sometimes, indeed, I was led to think that absorption of the atheromatous matter was taking place, and I do not see why even that should be impossible, for I have several times seen knuckles, lumpy from deposited matter, get entirely well.

Anatomy, then, physiology and experiment combined, not only help to make clear the nature of such cases as those above described, but they also explain such symptoms as blushing or its opposite, pallor of the skin, hypertrophy or atrophy, passive or active congestions and their consequences; those strange and passing nutritional disturbances of "change of life" in women, such as flushings, giddiness, warm and sudden sweatings, tendency to fatness, so well known to all of you; such and many other actions may arise either from reflex actions on the vasomotor centre in the medulla and be general over the body or be entirely confined to a particular spot, a particular vessel, a particular organ, or a particular area of those ever active agents of change, the lymphatic and cellular tissues.

Such actions may also have a cerebral origin and be transmitted direct from the brain; for example, the emotions may cause either suffusion of vessels from pleasure, and pallor and pinched expression from shock, fright, pain, and such like causes, for vasomotor filaments find their way down the spinal cord, apart from those which supply the sympathetic and the plexuses.

As with the vessels so with the thoracic and abdominal viscera. Anatomy and physiology teach us that their functions are involuntary and dependent upon and governed by the same sympathetic and vasomotor nervous systems and that in their muscular coats there are embedded large numbers of microscopic nerve plexuses which may act locally and separately or as a whole, at any given moment of time. Taking this for granted, we easily supply explanations of many discomforts and troubles, of intestinal origin, a local colic from a collection of flatus, or a mass of *feces* which may have remained lodged in some pouch of the colon allowing fluid or soft matter to pass by, old ulcerations or recent irritations causing local paresis, or perhaps more common than all, toxins of various kinds arising from the imperfect chemistry of digestion. Such toxins will of course, act according to their nature and according to their dose, some as sedatives, some as excitants, some as paralyzers and so on, just in the same way in fact as many of our alkaloidal poisons act. How strange it seems at first sight, that if you puncture an inflated intestine you frequently only succeed in emptying the punctured portion of its gaseous contents; you may have to puncture again in different parts to give complete and efficient relief to the general distension. Why is it, too, that often in "ballooned rectum" if you introduce a good-sized tube no air will escape. I have several times tested this by introducing my finger by the side of the tube and finding no obstruction, no physical cause that is, to prevent its escape. One would have expected that atmospheric pressure on the yielding abdominal walls would with certainty have ensured the expulsion of the flatus, but it does not always do so, and why? What is the active cause of the prevention of the contraction of the bowel? Are there muscles antagonistic to those which are paralysed, and are they for the time being resisting contraction? Such are problems which wait for solution, and their solution will be of great importance in the medical treatment of abdominal diseases in the future.

I have watched for several weeks on different

occasions in the last few years a case of constipation and enormous flatulent distension of the abdomen. No sign of any special cause for the obstruction could be discovered, but neither the patient nor the friends would consent to exploratory incisions or to colotomy. The long tube was used frequently with large quantities of warm water, and sixteen ounces of olive oil were daily administered, opium was given by the mouth, and almost nothing in the way of food. In use the tube could always be felt through the abdominal walls finding its way under the liver to the ascending colon. Eventually a large natural motion would be passed. This gentleman has had at least four or five attacks of this kind, and on one occasion when abroad the oil which entered per anum came up through the mouth. All one could tell of the case for certain was that there was complete paralysis of the circular fibres of the intestine. I regret that want of time prevents me from giving a more detailed account of this case, for it is profoundly interesting and suggestive; what I have said, however, is sufficient to show how important a part paresis of the intestine played throughout.

As important instances of vasomotor derangement few maladies are more marked or have created more interest of late years than exophthalmic goitre and myxœdema, the one apparently the antithesis of the other, the former with constant or constantly recurring dilatation of the vessels of the thyroid gland and of the heart and vessels of the body generally, the latter with a constant diminution of the gland and contraction of the vascular system in general, and yet at times, more often I think than is generally supposed, the one disease ends in the other. I have known two cases in which exophthalmic goitre ended in myxœdema; one I have watched for twenty-five years and the other for a long time and made myself sure of its history and sure of its course.

Cyclic albuminuria in young people, diabetes insipidus, and perhaps suppression of urine, may owe their origin to vasomotor changes.

Fatigue has appeared to me to be a frequent cause of these affections, but toxins may play a part, and they may originate in derangement of function arising from fatigue.

Chilblains, dead hands, and their congener, "Raynaud's disease," clearly show vasomotor changes, in the last, distinct change in the nerve trunks have also been found, but even such changes must originally have been connected with vasomotor action.

With regard to treatment, we would naturally give the first place to those great medicines of Nature, the chief medicines of Hippocrates and of Celsus, heat, light, electricity, fresh air exercise, massage, baths, change of scene and surroundings, and so forth,

You will not, I am sure, expect from me any wonderful novelty or series of novelties that apply to individual cases. I will only tell you, as shortly as I am able, what I have for many years found most generally useful, based on principles shadowed forth in what I have this evening tried to make clear.

You will naturally assume that vasomotor disturbances associated with acute gouty conditions cannot be cured in the same way as like disturbances due to neurasthenia, exophthalmic goitre, or myxœdema, and your assumption will be right.

The former of the groups, instances of which I have described, with localised hardened tender and painful vessels, would naturally be treated with rest, warmth, attention to the bowels, potash, colchicum, bromides, absence of alcohol, and strict attention to diet, but especially with rest and warmth and local sedatives. Very often a long walk and over-fatigue have appeared to have been the cause of the suffering.

The painful and dilated vessels from chill or blasts of wind will be managed on similar lines.

In the neurasthenic it will naturally be different.

A young lady, æt. 19, with suicidal melancholia and very bad family history, six feet high, and weighing only six stone, was put to bed and treated by the Weir-Mitchell method under the care of an excellent general practitioner and given, at my suggestion, grain doses of valerianate of zinc, and smaller doses of belladonna in pills twice daily and about fifteen grain doses of bromide of potassium at bedtime. The patient increased four stone in weight in eight weeks, her mental state steadily improved. She recovered perfectly and has remained well for over two years.

A lady who had suffered agony from repeated attacks of renal colic and hæmaturia, and who I soon found was highly neurotic, excessively thin, and badly nourished, had been stone deaf for eight years. I treated her for her neurotic symptoms only, with rest, valerianate of zinc and bromide at night. She rapidly improved, and the renal symptoms gradually disappeared. She now requested me to try something for her deafness, she had consulted several of our leading aurists and was told that it was nervous deafness and that there was no hope of recovery. I told her that I feared I could do nothing, but advised her to continue her zinc pills for two years and so establish her nerves in well doing. At the end of the two years she returned to me greatly improved in health and strength; the renal colic had not recurred, and she only suffered occasionally from attacks of migraine. At that time she thought sometimes she could hear sounds. Six months later she returned hearing perfectly, and able to take her full duties as head of a large house.

The return of her hearing was as unexpected to me as it was merciful to her. Since then, however, choosing to believe that the condition was functional and possibly amenable to treatment, I have not hesitated to treat other patients for their nerves when they complain of deafness and noises, and when my friends the aurists could not help them. Many of these cases have greatly improved and are improving still, but the improvement must be slow.

It is quite impossible in a paper like this to deal with every detail or even to comment upon the many maladies connected with vasomotor functions, with which I have already dealt in a general way, but I may assure you, from a long experience of valerian and of the valerianates, that in all cases of the neurasthenic type they are as much to be trusted now as ever they were by our so-called old-fashioned doctors, who knew more of prescribing and less of science than we of the present time.

Bromides, nitrites, opium, belladonna, strychnine, iron, all have their value in exceptional cases, but valerian in its several forms less often upsets the normal functions than iron, strychnine, and many tonics, and more often does good.

The influence of the nervous system on the blood vessels and upon the heart is all important in relation to blood pressure, regulating as it does the condition of the tone of the arteries, both through the central and peripheral vasomotor centres, and alterations in blood pressure above all things tend to alterations of function. All those medicines which help in controlling and co-ordinating the sympathetic and vasomotor nervous systems may be so employed as to bring comfort always, and cure frequently to many maladies of the nervous system which so often prove troublesome and intractable in our general practice.

University College, London.

MR. ASTOR, of millionaire fame, has given £20,000 in response to the appeal on behalf of this institution, and the sum of £30,000 has been promised, under certain conditions, by the Drapers Company, towards freeing it from debt. The total amount required is one million sterling.

INFANTILE FORM OF ARTICULAR RHEUMATISM, WITH CHRONIC ENLARGEMENT OF THE SPLEEN, LIVER AND LYMPHATIC GLANDS.

By F. PARKES WEBER, M.D., F.R.C.P.,
Physician to the German Hospital.

THE patient, A. S., a rather pale boy, *æt.* 4½, shown at the Medical Society of London, April 14th, 1902, is a typical example of an affection which has been well described by Dr. G. F. Still, and is usually classed as a variety of rheumatoid arthritis in children. In the present case there is some apparent enlargement of the knee- and elbow-joints, but the most marked change is the symmetrical swelling about the articulations of the hands and feet. The swelling, as investigated by the exploring syringe and Röntgen photographs, seems to be due to infiltration into the periarticular tissues, with little if any effusion into the synovial cavities. It is most marked over the proximal ends of the metacarpal and over the metatarsal bones. There is considerable limitation of movement in the cervical spinal column, and this accounts for the extreme movements of the eyeballs, which often give the face a remarkable appearance. The heart is enlarged. The apex beat is in the fifth space, one inch outside the nipple line (April 7th), and the first sound at the apex is replaced by a musical murmur. The spleen and liver extend considerably below the ribs, and the lymphatic glands in the neck, axillæ and groins are enlarged, but not greatly so. The temperature has not reached 100° F. since February 3rd, and of late the child has had a good appetite, has appeared to put on flesh, and has seemed happy and free from pain and tenderness in the joints. The urine contains no albumin or sugar. Blood count (January 26th, 1902) shows 4,600,000 red and 31,000 white corpuscles in the cubic millimetre.

From November to December, 1900, the boy had an acute disease, said to have been articular rheumatism. Before this he could walk and was apparently healthy. The cervical rigidity has lasted since the Christmas of 1900. It caused me at one time to suspect the presence of spinal caries. The swelling of the hands was noticed a short time before May 1st, 1901, when he was admitted into the German Hospital. The articular affection of the feet was little marked on admission, but was a decided feature of the case by the end of August, 1901. Under treatment by rest, aspirin, iodide of iron, arsenic, malt, &c., the boy's condition has fluctuated considerably in regard to swelling and tenderness of joints and general appearance, but wasting of the muscles of the limbs has progressed. Occasionally there has been moderate fever, and about the beginning of November, 1901, there was a definite attack of endocarditis, and the heart, which previously had appeared healthy or very slightly dilated, showed signs of disease of the mitral valve.

It is this attack of endocarditis and the fact of pericardial adhesions having been found in other cases which make me think that the affection is more allied to articular rheumatism than to any forms of rheumatoid arthritis in adults. Supposing the ordinary cases of acute and subacute rheumatism to be due to a specific microbic affection, as the recent work of Dr. F. J. Poynton and Dr. A. Paine makes probable, cases like the present one might perhaps be due to the same specific cause, the clinical differences being explained as modifications resulting from the age of the patients. In the same way, tuberculosis in young children is clinically generally very different from tuberculosis in adults. With the consent of the parents, I asked Dr. Poynton and Dr. Paine to try

if they could obtain microbic cultivations from the joints. This they kindly attempted in the commencement of the present year, but the attempt failed, the exudation apparently being gelatinous and in the periarticular tissues. There was little, if any, effusion into the cavities of the joints.

ELECTRIC LIGHT CONJUNCTIVITIS. (a)

By HAROLD B. GRIMSDALE, F.R.C.S.,
Assistant Surgeon to the Royal Westminster Ophthalmic Hospital, Assistant Ophthalmic Surgeon to St. George's Hospital.

ONE variety of conjunctivitis resulting from exposure to electric light is startling in its onset and course, and most alarming to the patient. It is a disease not without interest to the general practitioner, who may be called on to treat a condition not unlikely to cause undue alarm, unless he be familiar with it. It is not a very common condition, and it has received scant acknowledgment in literature, although its congenere, snow-blindness, is among the best known ailments of Arctic voyagers.

Fuchs, in his well-known text-book, dismisses the subject in a few words printed in small type at the end of his paragraph on injuries of the conjunctiva. After describing the inflammation that results from the action of irritant substances on the conjunctiva, he says: "A similar picture is presented by that variety of conjunctivitis which occurs after the action of intense light upon the eye, as, for example, after dazzling by the reflection from snow (snow-blindness) or by the electric arc light. In violent cases of this sort there are found besides the inflammation of the conjunctiva, contraction of the pupil and also slight opacities and erosions of the cornea. These symptoms, like the erythema of the skin, occurring as a result of insolation, are produced by the action of the ultra-violet, chemically active light rays. These cases of traumatic conjunctivitis, in spite of the violent symptoms which they present in their beginning, generally get well within a few days without further bad results." Other authors are even briefer in their descriptions, and some do not mention the condition at all.

Notes of a few cases which have occurred to me may therefore not be uninteresting.

W. P., a labourer employed at the Electric Light Company's Works, attended St. George's Hospital in February, 1897. Both eyes were streaming with tears, and the conjunctiva was chemosed and red-dened; at the margin of the cornea were several small papules. Vision was considerably reduced.

The history he gave was that he had on the preceding afternoon been engaged in repairing an arc lamp which was giving light all the time. He noticed several times during the process that the after-image of the lamp was unusually troublesome and prevented his working with comfort for long together. He finished his afternoon's work and went home. On his arrival he was attacked by great photophobia and lacrymation; spasm of the lids, however, was not in his case a troublesome symptom, and therefore the patient was not as alarmed as is often the case. The absence of blepharospasm allowed of examination of the visual acuity, which it was found to be $\frac{1}{10}$, the reduction being probably due to the lacrymation. The cornea was clear and bright; around its margins, however, were a few small papules such as often indicate the first stage of phlyctenulæ.

The immediate symptoms were readily combated by cocaine and cold compresses. Within twenty-four hours the photophobia had almost ceased, but the

(a) Abstract of Paper read before the South-West London Medical Society on Wednesday, April 9th, 1902.

lacrymation and injection were rather more persistent. They yielded to boracic acid irrigation within a few days, and the man was discharged with normal vision. He was advised to wear smoked glasses during the work.

This case has been followed by two others in whom the symptoms and course were almost identical, except that blepharospasm was more marked. In all the exposure to the light had been continuous for some hours.

Occasionally the exciting cause may be of very short duration: G. W., *et.* 26, electrician, attended St. George's Hospital in December, and gave the following history. He had on the preceding afternoon been engaged in refitting the ceiling lamps of a room lit by the ordinary incandescent type of lamp, when by some bad fortune a large part of the current was short-circuited, and a blinding flash occurred. He felt no shock, but he was "half blinded," and complained of rather sharp pain. This only lasted a few minutes, but he was inconvenienced for some hours by a positive central scotoma. Towards evening the symptoms disappeared, and he went to bed anticipating no further trouble. He was aroused about 2 a.m. by great itching of the eyes, which soon became almost unbearable. He felt as if the lids were covered with sand. Tears were poured out in streams; there was, however, no blepharospasm. When I saw him the same day the disease had evidently spent its chief force. The lids were still very red, and showed many papillae, but the flow of tears had ceased, and the pain was subsiding. There was no central scotoma, vision normal. I gave him a weak lotion of boracic acid, and a 1 per cent. solution of cocaine to use as drops if the pain proved troublesome. He was quite well in two days.

The rarity of the disease is shown by the fact that none of these workmen had ever heard of the accident among their fellows.

In the last instance which I have to mention the patient was himself a medical man, and had been carrying on some experiments at a general hospital with lights especially rich in ultra-violet rays. He had noticed on several occasions a feeling of spasm of the lids, which lasted a few minutes, and then subsided without any serious trouble, and had thought nothing about it. On October 27th, after a long day's work in this light, he was attacked with considerable discomfort and lacrymation while on his way home. On arrival at home he found himself unable to read, and went out about 5.30 p.m. "to walk it off." He was out for about an hour, during which time the spasm of the lids came on violently, so that he was hardly able to find his way, since the eyes could not be kept open, and when opened were drowned in tears, which ran copiously down the face. He had repeated difficulty in reaching his home.

I saw him a few hours later. At that time the lids were kept tightly closed, and could not be opened voluntarily, the conjunctiva was much injected, lacrymation copious, pupils small. I could not examine their reactions, as the smallest entrance of light gave rise to great discomfort. The blepharospasm was extreme, and the sensation was compared to putting a finger in the eye. He was when I saw him sitting up in bed with his face, covered by his hands, buried between his knees. I at once instilled some cocaine, which gave rise to great smarting, followed in a short time by almost complete relief, and prescribed iced compresses to be repeated through the night. These soon produced a soothing effect, and in about two hours he was able to sleep. There were several milder attacks of pain before morning, but the iced pads soon quieted them, and no further application of cocaine was necessary.

Later he used some solution of boracic acid, 10 grs. ad 3j. as a lotion. The next day he was much better, and was able to open the eyes fairly well. The lacrymation had diminished, and the injection was less. The spasm showed signs of returning on one or two occasions, but was easily controlled by cold. In thirty-six hours all signs of injection had gone, and he was able to resume work, but on my advice with dark goggles to prevent the access of the ultra-violet rays.

It will be seen from the cases given that the disease is more alarming than serious. Fuchs, it is true, talks of small ulcers of the cornea, but I have never seen any in those patients who have been under my care. In all instances the disease lasts only a few days, and relapses are, so far as I have seen, rare, if proper precautions are taken.

Whether the cold compresses have any great effect in the cure or not, they at least afford great relief, and are most comforting to the patient.

The best method of application is to have a fairly big block of ice wrapped up in a piece of an old blanket or a thick woollen shawl. On this are placed three or four pads of gamgee tissue or compresses of linen. They are, of course, covered over by the woollen rug. They are then placed on the eyes in rotation; as soon as one gets warmed by the heat of the body it is removed and relaid on the ice, and the next is placed in its stead. They require changing every few minutes, probably every five or ten. As the patient is almost blind from the blepharospasm and the lacrymation he is not able to do this for himself, and it therefore involves the constant attention of a nurse.

I inquired from Dr. W. whether any of the cases of facial lupus, which he was treating with this light, had complained of any inconvenience. He told me "no," at that time, but a few days later one of his subjects was attacked twelve hours after the sitting with blepharospasm, lasting several hours.

Since then he has protected the eyes from the direct action of the rays.

The last case—that of Dr. W.—is of more than usual interest in showing that it is the ultra-violet rays and not the general illumination which produces these effects. The light in which the subject was working was not extraordinarily brilliant, but had been chosen as being rich in ultra-violet rays, for the treatment of lupus of the skin.

This conclusion is indeed only what we should have expected; but it serves as a proof that our theoretical speculations were correct.

Probably dark yellow glasses would stop the active rays and therefore prevent snow-blindness even better than the ordinary smoke tint, but there can be little doubt that the common blue glass, which permits the passage of ultra-violet rays, is of little value in such circumstances.

The question "how the conjunctivitis is produced" is not very easy to settle. It can hardly be from direct injury to the conjunctiva, otherwise we should not get the interval of quiescence after the immediate results have passed off, in which the subject is free from all pain before the acute signs come on once more. It must, therefore, be due to a disturbance of the nervous system, and especially the vascular centres, by direct stimulation of the afferent nerves, or the rays must cause some chemical change in the conjunctiva, whose products act as strong irritants producing the local inflammation. It seems hardly likely that a momentary stimulation would have the latter power, and I am disposed to think that the former is the more probable.

IODINE AS A SPECIFIC REMEDY FOR SURGICAL TUBERCULOSIS.

By DR. MARGRETHE HERMANSEN,
Of Copenhagen.

IN calling the attention of my professional colleagues to some experiments I have been making in the last two and a-half years with iodine as a specific remedy in surgical tuberculosis, I must admit that I am unable to adduce a sufficient number of cases to determine the exact value of the treatment. Nevertheless, I believe that the method at all events will prove a help in many cases, and for this reason I hope that my professional colleagues will give the treatment a thorough trial by treating a greater number of patients than I alone have been able to collect.

The following facts have guided me in my work :—

1. The relationship between tuberculosis and syphilis, which is so evident both in the histological products of these diseases (notably in the arrangement and distribution of the cellular elements in tuberculosis and in syphilis), and in their infectious, chronic and recurrent character.

2. The value with which iodine, one of our best remedies in syphilis, has always been credited by the medical world as a remedy against scrofula, even at a period when it was not known that scrofula had the same origin as tuberculosis.

This led me to the hypothesis that iodine was a specific not only against scrofula, but also against other forms of tuberculosis (as iodide of potassium is in tertiary syphilis, and as mercury is in the primary and secondary stages), and that a permanent cure might be obtained if iodine were only used as a specific, *i.e.*, rationally, in large doses, and for a very long period with regular intervals, several times a year (during the first years after the infection), the treatment being repeated should there be the least sign of recurrence (just as mercury is used in syphilis). By this intense and persistent treatment the tuberculous material will by-and-bye be eliminated from the body, the constitution fortified against it during the campaign, and the bacilli at last extinguished.

My idea is that the patients will be cured if only they get sufficient iodine, but this is the *sine qua non*, for how can a chronic disease be vanquished, if it be not treated perseveringly? Would a syphilitic patient be cured if mercurial inunctions were not repeated at intervals?

My experiments seem to verify the hypothesis at least as far as surgical tuberculosis goes. In tuberculosis of the lungs iodine given by the mouth does not seem to have any specific value, it only reinforces the general health of the patient and stimulates the appetite. I have recently given iodine in cases of phthisis in another form, *viz.*, in the form of iodine ointments (similar to mercurial ointments). The number of the patients has been small, but the results so far have been very satisfactory. [Perhaps the iodine ointment would be a better form for exhibiting iodine in surgical tuberculosis; I have not tried it yet.] I think, too, this treatment had better be tried in a sanatorium, where one can observe the patients day by day. A medical friend of mine has just written to me that three of his patients have tried the iodine ointments in cases of phthisis and have much improved.

In regard to surgical tuberculosis, I began to try the method in cases where the operative treatment had had no effect in arresting the disease, having ascertained, as far as possible, that the patients had never had syphilis.

I give the iodine in the old form, often used against scrofula :—

Inf. rhei alkalini;
Sol. pot. tartrat;
Tinct. cinchon. comp., aa gram. 30;
Sol. iodi. spirit (5% iodum), gram. 15;
Tinct. pomi ferratæ, gram. 20.

[Pharmacopœia Danica.]

I generally give my patients one teaspoonful of this mixture three times a day (half an hour or more after meals in a little water), but so that the patients begin with smaller doses (half a teaspoonful), and reach the larger doses in the course of three to four days. The treatment is continued for two to six months, when it is abandoned for a time, then they take the medicine again for two to three months, then again pause, and so on, until the disease seems to be quite extinguished.

In spite of the large doses (some patients have taken half an ounce three times a day), one scarcely ever sees any case of iodism, at most a slight degree of indigestion that passes away quickly, when the treatment is stopped for a few days, or when smaller doses are given. In cases requiring prolonged treatment I have sometimes given the patients a little bicarbonate of sodium with the object of preventing iodism. I have only been able to get about twenty cases in the above-named time, and all of these I have not been able to carry through, but the very good results I have had in most cases have encouraged me to try to get the method tested on a larger scale.

I have noticed that the treatment requires that the stomach and the intestines should be free from actual tuberculous lesions, and in most cases it is desirable that there should be free drainage from the tuberculous focus. Of course, the surgical treatment in many cases cannot be dispensed with, but after the operation the remedy shows its good effects, as the abscesses, &c., heal quickly and with firm cicatrices without leaving fistulæ. It is most advantageous in these cases to let the patients take the medicine for from two to four months before the operative treatment, and continue it afterwards.

Of the patients I have treated about one-half had tuberculosis of the bones, but I have also had cases of conjunctivitis tuberculosa, tuberculous glandular tumours, tuberculosis of the testis, &c. Most of these cases have given good results. In patients, who have had tuberculosis for many years, and have been operated upon several times without being cured, old fistulæ have healed, they have regained their strength to work, together with their normal appearance and appetite. The only case of lupus that I have had, and two cases of tuberculosis of the intestines were treated without result.

I have noticed that patients whom I have allowed to stop the treatment after having used the remedy for a shorter time, have suffered from recurrence, though they were much improved, and in some instances appeared to be cured. The recurrence passed away quickly when the treatment was renewed, and later on the recurrence took place with gradually lengthening intervals, until at last they ceased altogether.

I found, too, that patients suffering from this disease, as in syphilis, could ultimately dispense with specific treatment for longer and longer periods.

Whether the cure is permanent it is of course impossible at present to decide, as not more than one and a-half to one year has elapsed since my first patients stopped the treatment.

I shall give a short account of some of the cases :

I. Tuberculous Abscess of the Femur.—H. S., shopman, son of a labourer, æt. 19. Much tuberculosis

in the family, the father having recently died of phthisis; a brother died of tuberculosis some years ago.

When he commenced the treatment on May 23rd, 1900, he had been ill for about two years, and had been operated for the first time eighteen months previously for a tuberculous abscess in the right inguinal region. After the operation there had remained a suppurating fistula in the place. In April, 1900, he had been operated again (scraped) for a tuberculous abscess on the inside of the right femur; a tuberculous focus was found in the descending ramus of the pubis; Koch's bacilli were found in the pus.

I saw him for the first time, when he had been at home some time after the operation. On the inside of the upper part of the right femur he had a fistula, which was suppurating freely. He was very emaciated, pale, and anæmic, and could only with difficulty drag himself along with the aid of two sticks. He had no appetite at all. No cough or diarrhoea.

He began the treatment on May 23rd, 1900, with half a teaspoonful of the mixture three times a day, and after a few days reached the full dose of one teaspoonful three times a day. He improved quickly after the first fourteen days had elapsed, and speedily developed a very good appetite. On July 15th there was but scanty secretion from the fistula; he ate well, had gained much in strength, and walked easily without the aid of a stick. On July 29th the fistula had almost healed and his general health was daily improving. He continued to take the medicine for about four and a-half months in all. In September, 1900, he went as a sailor. I saw him again on January 29th, 1902. The fistula had quite healed. No recurrence of any kind. He was still working as a sailor.

II. *Chronic Tuberculous Conjunctivitis*.—F. H., merchant, æt. 47. No tuberculosis in the family. Denied ever having had syphilis. When he was æt. 9 he had kerato-conjunctivitis of both eyes after scarlatina. The keratitis was cured; the conjunctivitis remained persistent though treated by a specialist. In December, 1899, he began the treatment with half a teaspoonful of the mixture (a) three times a day, and a short time after he took one teaspoonful three times a day. There was at that time a sero-purulent secretion with some redness and œdema of the conjunctivæ of both eyes and very marked blepharitis marginalis with crust-covered ulcerations on the margins of the lids; pain and photophobia were marked, so that he was obliged always to wear smoked spectacles and could only read for a very short time. His general health was not good; he had some emphysema and myocarditis.

A fortnight after commencing the treatment he began to improve; the ulcerations on the margins of the eyelids began to be cleaner, and the pain and photophobia became less pronounced. The improvement went on steadily until February 25th, 1900, when he got a severe attack of influenza and was obliged to cease the treatment for three weeks, during this interval the eyes became worse again, but still not so bad as before the commencement of the treatment. When he had recovered from this attack he took the medicine again, and in June, 1900, the eyes were quite well; the blepharitis had gone, there was no secretion from the conjunctivæ, and neither pain nor photophobia. He no longer wore his dark spectacles and was able to read and write comfortably.

As he began to get a little diarrhoea in July, I stopped the treatment for three months, at the end of this period he began to have a little secretion from the eyes, with a little pain and photophobia, but

these symptoms subsided in the course of a few days on his taking the medicine, but I allowed him to continue to take the medicine for two months. Since then he has not applied to me for any further treatment and the eyes were well the last time I saw him in the spring of 1901.

CASE III. *Tuberculous Glands of the Neck*.—M. S., housekeeper, æt. 45. Nine years ago she was operated upon for tuberculous glandular tumour on the left side of the neck beneath the angle of the jaw; after the operation there remained a fistulous ulcer which only healed six months later.

In the summer of 1900 she noticed a little glandular tumour beneath the angle of the left maxilla, which had not been removed at the previous operation. This began to grow and caused her some discomfort and at the same time her general health began to suffer.

She began the treatment in the usual way in August, 1900. The glandular tumour continued to grow steadily until the end of December, when it was the size of a small hen's egg. As it pained her a good deal, and there were signs of inflammation and suppuration in the tumour it was extirpated on January 1st, 1901. The wound healed in the course of a week and her general health forthwith after the operation improved. She took the medicine for about a month and has remained well ever since.

CASE IV. *Lupus of the Face*.—Girl of the labouring class. No effect whatever.

CASE V. *Tuberculosis of the Intestines. Phthisis Pulmonum*.—A. P., daughter of a labourer, æt. 16. She was unable to tolerate the treatment, which gave rise to intestinal disturbance.

CASE VI. *Tuberculosis of the Intestines. Spondylitis*.—O. N., æt. 8, son of a labourer. Could not take the medicine.

CASE VII. *Coxitis Dextra*.—A. D., æt. 30, typographer. Disease began in his 18th year. Had been operated upon five times. Began treatment at the end of October, 1900. Fistula with a little secretion remained in front of the hip-joints; he had not been able to work for a very long time, and was thin and weak. By October, 1901, the fistula had healed, his natural strength had returned, and he was able to resume work when he had taken the medicine for a short time. He continued the medicine for six months with an interval of four months; after the first four months he had a slight recurrence in the interval, but is now quite well and is at work.

CASE VIII. *Coxitis Dextra*.—I. P., æt. 5, daughter of a shopman. Very tuberculous family. October 31st, 1900. Had been ill for six months. Third stage of coxitis, no pain or tenderness; the process seemed to have come to a standstill. She was emaciated, and had no appetite. She took the medicine (in smaller doses), and in a short time her appetite returned and her general appearance greatly improved, but unhappily I lost sight of her.

CASE IX. *Tuberculosis of both Testes*.—O. I., labourer, æt. 42. Disease began January, 1900, in the left testis. In March, 1900, the testicle was removed. In June, 1900, the disease supervened in the right testicle, and in August, 1900, it was scraped with a sharp spoon. He began to take the medicine on November 14th, 1900. He had then two fistulæ discharging sero-purulent matter on the left side of the scrotum. The right testis and epididymis formed a hard tumefaction as large as a walnut; in the middle of it there was a suppurating fistula. General health good. By April 15th, 1901, two fistulæ had healed. A fistula remained on the left side of the scrotum with very little secretion. The tumefaction in the right half of the scrotum felt softer and the fistula there had healed.

(a) In the treatment of the two cases of conjunctivitis a slight difference was made in the composition of the mixture, the solution of tartrate of potassium being replaced by bromide of potassium.

Clinical Records.

MISCARRIAGE AND DIFFICULT LABOUR AFTER VENTROFIXATION; REMOVAL OF OVARIAN BLOOD CYST; EXTENSIVE ATTACHMENT OF THE UTERUS TO THE ABDOMINAL WALL. (a)

By H. MACNAUGHTON-JONES, M.D., &c.

THE lady, æt. 33, from whom the adnexa exhibited were removed, had been married for two years. The year before her marriage ventrofixation had been performed for bladder symptoms caused by a large and anteverted uterus. This relieved the pain and inconvenience. She miscarried at five months after marriage. Labour at full term occurred in September, 1901. There was a difficult labour with some malposition. At the end of a fortnight she suffered from some puerperal symptoms, but these passed off and the first catamenial period was normal. After this pain commenced in the right side and right leg, which was excessive at the periods, these being profuse with some intermediate discharge. This was followed by tenderness over the left side. On examination an adnexal tumour at the right side was found. At the operation a blood cyst of the ovary about the size of an orange was removed. The uterus was found firmly connected to the abdominal wall by a band of fascia about an inch in width. As after the previous operation, on the third day there were signs of an iodoform eruption, and the dressing was removed from the wound. The patient was subject to attacks of acute rheumatism, and on the fourth day her temperature rose to 103° and an attack of acute rheumatism supervened, attended by swelling and pain in her hands and body generally. Under full doses of salicylic this subsided, but there was a recrudescence on the ninth day. This also yielded to treatment, and the rest of the recovery was uninterrupted.

Dr. Macnaughton-Jones drew special attention to the fixation of the uterus, as indicating the danger of ventrofixation as compared with ventro-suspension, or Olshausen's operation (doubling the round ligaments and attaching them to the peritoneum and sub-peritoneal fascia) during the childbearing period of life. Only in a limited class of case, and after a certain age, was ventrofixation the operation of selection.

COFFEE-GROUND VOMITING WITH HÆMATEMESIS AFTER HYSTERECTOMY. (a)

By H. MACNAUGHTON-JONES, M.D., &c.

IN showing the tumour, which was a large multiple myoma, with sub-peritoneal offshoots, Dr. Macnaughton-Jones said that the case was illustrative of the President's remarks made at the last meeting on the almost universally fatal nature of this class of vomiting. The patient was a woman, æt. 41, unmarried. Her general health had been for some time steadily declining from the combined causes of pain and hæmorrhage. She was not in independent circumstances, and had to work for her support. The following were brief notes of the case:—

The operation, myo-hysterectomy, was completed without any accident, and was practically bloodless. There was a large portion of omentum adherent to the anterior surface of the tumour. On the day of operation there was nothing special to remark. At six o'clock her temperature rose to 100°, and her pulse was 96. Her respirations were 28 per minute. She did not complain of much pain, and had some hours sleep that night. In fact, all through she complained but little of any abdominal pain, and there was no abdominal distension until some hours before death, as she passed flatus from the bowel freely. On the morning of the second day the pulse was 96, the temperature 101·6°, and she complained of some cardiac distress and palpitation. Her temperature at 10 p.m. this day was 100·1°. The note taken at 9.20 p.m. on the second day was, "patient

(a) Brought before the British Gynecological Society, April 10th, 1902.

had a comfortable day, headache better, no palpitation, no sickness." At 9 o'clock the following morning the report was, "passed flatus per rectum, had a comfortable night, sleeping in all nine hours. The temperature at 6 a.m. was 99·4°, and the pulse 96; respirations 20. At 10 a.m. her temperature was 99·8°, her pulse 98, her respirations 22, and she had passed a total of 28 ounces of urine in the twenty-four hours. Up to this time she had been taking nothing save hot water, barley water and milk, some weak tea with milk, and some Brand's and Valentine's essences. Altogether, she had had two hypodermic injections of morphia. Her first complaint of any feeling of sickness was at 6 p.m. on the evening of the third day. That night she had two grains of calomel. She was still passing a quantity of flatus by the rectum. She did not have a comfortable night, and complained a good deal of thirst. At 2 a.m. her temperature was 99·4°, and 99·1° at 6 a.m. When it was taken at 10 o'clock it was subnormal, 97°. The pulse had been steadily rising for the twelve previous hours, and with the fall of temperature had risen from 112 to 136. At the same time she vomited a quantity of typical coffee-ground matter. Strychnine injections and nutrient enemata were resorted to, but the vomiting continued, the pulse becoming more rapid and very feeble. Saline infra-mammary injections were given, and digitalis by the bowel. Thinking there might be some adhesions with the divided omentum, I determined to open the wound. This I did at 3 p.m., but found nothing either in the wound or the appearance of the bowel to account for her condition. She died shortly after. It was a noteworthy coincidence in connection with this case that two of the patient's sisters had died within a few days after their first labour from what the family understood to be called "sudden death."

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, APRIL 10TH, 1902.

J. HALLIDAY CROOM, M.D., President, in the Chair.

DR. MACNAUGHTON-JONES showed an ovarian blood cyst removed from a patient in whom ventrofixation had been followed by miscarriage and difficult labour; and also, as illustrating the President's remarks at a previous meeting, a large multiple myoma removed by hysterectomy, which had been followed by hæmatemesis, typical coffee-ground vomiting.

[Notes of these cases will be found under the heading of "Clinical Records."]

In the discussion of the former case,

Dr. HEYWOOD SMITH asked whether there had been any stretching of the fixation adhesions such as Howard Kelly depicted in his book. He had been dissatisfied with the results of ventrofixation himself, as, though at first efficient, the adhesions had in one case stretched, and the retroflexion had recurred.

Mr. CHARLES RYALL said that though the uterus was intimately adherent to the abdominal wall over an area as large as a shilling, the fact that the woman had gone to full term and borne a healthy child was extremely interesting.

Dr. MACNAUGHTON-JONES, in reply, said that retroflexion had not recurred after any ventrofixation he had himself performed; he considered the operation a perfect cure for such displacement, but not one to be done during childbearing age, as doubling the round ligaments and attaching the uterus by them to the subperitoneal fascia had proved to be much safer.

The President said that though he had done the operation for retroversion, and still oftener for prolapse, he had met with reverses not only from subsequent pregnancy but also from recurrence, and was in sympathy with Dr. Heywood Smith as well as with Dr. Macnaughton-Jones. With regard to the case of hæmatemesis after hysterectomy he had never seen a case in which coffee-ground vomiting occurred which did not end fatally, and was convinced that its occur-

ence was invariably due to septicæmia in some form or other.

The PRESIDENT then read a paper on

DECIDUOMA MALIGNUM,

which we hope to publish in *extenso* in an early number. It was illustrated by diagrams, and a remarkable series of specimens of the primary disease and metastases and microscopical sections from a case, occurring six years after the last-known pregnancy, in which there had been absolutely no uterine hæmorrhage throughout.

Dr. HAYWOOD SMITH said that the chief points suggested by the very instructive paper for which they had to thank their President, and which might be further elucidated by discussion were, the prospects of those affected with this disease, its clinical aspects, and especially those present before the aid of the microscope was available, whether an offensive discharge during or after pregnancy should suggest its presence; how we could distinguish between this disease and carcinoma of the body of the uterus; and generally its differential diagnosis from other forms of malignant disease. Metastatic deposits undoubtedly occurred very early, but we were uninformed as to how soon after impregnation the primary growth might develop. Above all, what were the direct indications for interference? It was a point worth notice that in the case related not only had hæmorrhage been absent but that the introduction of the sound, though it touched friable tissue, caused no appreciable loss of blood as it would have done in carcinoma of the body.

Dr. HERBERT SNOW reminded the Fellows that at the last very well-attended discussion by the Society upon deciduoma malignum the general feeling was that it was very doubtful whether that disease was essentially different from other malignant developments in the uterus, carcinoma, sarcoma, or myxo-sarcoma. He was not aware that any particular form of cell was characteristic of the disease, nor could those seen in the diagrams exhibited be distinguished as in any way different from forms often found in myxoma, and depicted in his own "Treatise on Cancer." Branching nucleated cells were characteristic of the growth of connective tissue which, as in myxoma, was secondarily associated with mucoid degeneration. There was a great similarity between the natural processes of placenta formation and malignant growth, especially in regard to epithelial proliferation and invasion of surrounding tissue.

Dr. MACNAUGHTON-JONES pointed out that fourteen years before Sænger's cases, in 1875, in Virchow's "Archiv," Maier and Hegar had reported on malignant uterine tumours of a decidual origin. There could be no doubt that now the consensus of opinion of the majority, including some of the best living pathologists, is that the special and characteristic features and etiological relations of deciduoma malignum entitle it to a distinct place among the malignant affections of the uterus. The large giant cells were peculiar in their irregular distribution, the absence of intercellular connections, and the existence side by side with these of other proliferating groups of cells of the sarcomatous type, together with the typical neoplastic tissue into which the multinucleated processes extended, producing the vascular degenerations and necrotic areas, were features which differentiated the cellular elements of this affection from those of other sarcomatous growths. That certain pathological features were associated with decidual elements, and occurred in connection with products of gestation, gave the disease its distinct etiological significance. No doubt views vary considerably on some points connected with its pathology, its epithelial or villous origin, and its relation to the syncytium. This was not to be wondered at when we remembered the unsettled views regarding the maternal or foetal origin of the latter, though from more recent researches, especially those of Williams and Salmon, it seems to be now settled that the syncytial cells have a foetal origin. Passing over, however, these divergences as to its pathology, the point for them to consider was rather the practical one of the clinical features of a disease which, when once recognised, indicated removal of the uterus. As Marchand had said, it was a matter of indifference

whether they relegated it to carcinoma or sarcoma. The hæmorrhage, the fœtor, the enlarged, softened and crumbling uterus, doubtless made differential diagnosis a matter of considerable difficulty. The occurrence of pulmonary metastasis had been emphasised by Newmann and Treub, so much so that hæmoptysis in early pregnancy was looked on by these observers with suspicion. With regard to curettage, with clinical symptoms such as those attending upon deciduoma, they were bound to curette and necessarily to have the *débris* carefully examined. If, in addition, the characteristic pathological appearances were present, the only remedy was extirpation. To show how difficult diagnosis might be in cases in which symptoms arose of a nature similar to those occurring in deciduoma, and with an ascertained relation to products of gestation, he would wish to read the notes of a case which will be found under "Clinical Records."

Mr. CHARLES RYALL thought that in the differentiation of deciduoma malignum from other forms of malignant disease two points were of particular importance. In no other type of such disease were metastases encountered so early in distant organs, nor were there the same transplantations in the lower genital tract.

The PRESIDENT, in reply, said the difficulty of diagnosis was, as Dr. Heywood Smith had pointed out, considerable. If, after the removal of a myxomatous mass from the uterus the patient had some hæmorrhage, and on curetting a villus, or even proliferating cells were found in the *débris*, the evidence was not decisive; but in deciduoma the use of the curette generally caused enormous hæmorrhage, which at once aroused suspicion, and if repeated hæmorrhages followed the expulsion of a myxoma, if the uterus were enlarged and there was a plentiful foul and sanious discharge, and corroborative evidence was obtained by the microscope, one might safely conclude that one had to deal with deciduoma malignum. He thought that Dr. Macnaughton-Jones's remarks, with which he entirely concurred, were a sufficient reply to Dr. Snow's doubts as to deciduoma being distinct from other forms of malignant affections of the uterus.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD ON FRIDAY, APRIL 11TH, 1902, AT THE ROYAL COLLEGE OF PHYSICIANS.

SIR CHRISTOPHER NIXON, M.D., President in the Chair.

Dr. J. G. COLEMAN exhibited a case of "sporadic cretinism" in a child, five years of age. The case was particularly well-marked, all the classic symptoms of the disease being present.

Mr. E. F. TOBIN then read his paper on Some Medical Aspects of Four Consecutive Cases of

PERFORATED GASTRIC ULCER

successfully operated on, all of which were together in St. Vincent's Hospital at the opening of the present session. Three of the patients were young domestic servants. In all the cases the position of the ulcer was the same, viz., an inch or two in front of the œsophageal opening. This, he said, was the most common spot for the surgeon to find a perforation. Why was it so? He believed that perforation was the penalty the overworked anæmic class that furnished most cases paid for being obliged to carry themselves upright from early rising to late bed-time. The liver in such patients is not braced up owing to the laxity of tissue, and their being on their legs all day long. The stomach, owing to its fixity to the diaphragm, is being continually drawn through a long range of movement in the breathing that is induced by journeys up and down stairs. Now given congestion of the area under consideration, that which extends from the œsophagus under the liver, it is easy to understand how the pressure and movement referred would in anæmic subjects cause congestion to pass to ulceration, and ulceration to sloughing; also how rest in the recumbent position is

such a healing force in such cases. He referred to the disastrous effects of movement in cases of perforation and laid down the rule that the surgeon should be called to the patient, and that no patient should be moved till the opening had been closed. The convenience of operating in hospital did not cover the loss from transportation. He narrated a case on which he operated successfully with the rudest appliances. Shock should not prevent one operating at once. It is not mere nervous shock where nothing harmful is going on while you wait for the patient to come round. On the contrary, changes are going on that may lead to thrombosis of the mesenteric nerves and render operation useless. As regards prevention, he pointed out that we are constantly advising sufferers of the servant class to rest in the intervals of work, at the same time knowing that in most houses, short of going to bed, there is no means of them properly carrying out the suggestion offered.

Dr. REDMOND thought the great difficulty in such cases was the diagnosis of perforation; there may be little or no shock. In one of his cases, he found the patient sitting in bed leaning forward, supported by two friends and crying out with pain. She had been in excellent health all day and had eaten heartily of mutton at dinner. There was no diminution of the area of liver dulness. He recommended operation; a perforation at the cardiac extremity of the stomach was found and sutured, and the patient made a good recovery.

Mr. H. G. CROLY thought they should all be very grateful to Mr. Tobin for bringing these cases forward, and particularly for his sound advice to them to bring the surgeon to the patient. Gastric ulcer cases do not bear carriage. To convey such a case any distance in a cab, jolting along and having the stomach contents extravasated into the peritoneum was to court death. On the other hand, no cases are so readily dealt with in their own homes. All the surgeon requires is a knife, a forceps, a needle, and a bit of thread. If necessary he would prefer to operate first and convey the patient to hospital afterwards. His advice in all these cases, even in cases where the diagnosis was not absolute, was to operate without delay; a laparotomy will ensure an accurate diagnosis, and, if an ulcer is not present, the incision in no way increases the patient's risk. He thinks Mr. Tobin's paper is full of sound advice and a creditable record of good surgery.

Dr. KENNEDY said that he found the patient he sent to Mr. Tobin, rolling about in bed as if in hysterics. He was with her an hour after perforation, and did not find the shock as severe as the text-books led him to expect. The abdomen was not distended; the abdominal muscles were rigid; there was no vomiting; one hour later she looked as if dying. Three months before seeing this case, he was called to see a similar case, though forty hours had elapsed from the perforation there was no vomiting, an operation was performed and the patient died in a few hours. This girl had been treated for gastric ulcer in St. Vincent's Hospital, from which she had been discharged as well. At the time of the perforation she was at business in a draper's shop, and continued working for an hour after the accident. He recommends home operations.

Dr. WINTER found no diminution of liver dulness in a case which he had observed; there was a complete absence of shock, and no vomiting. Removing the patient from her home to hospital occupied three-quarters of an hour. He would like to hear from Mr. Tobin the after history of his cases, for there was an idea that such cases did not always do well.

Dr. JAMES LITTLE had seen many cases which had all the symptoms of perforation recover without operation. In one case, when called in consultation, he found what might be called a typical case of perforation with the peritonitis of extravasation, yet that patient recovered, and for years past she hunts regularly.

Dr. FINNY looked on the diagnosis of the perforation as the real difficulty in these cases. One of his patients who had all the typical symptoms of perforation, vomiting, tympany, pain, and so forth, was operated on three hours after the onset of the attack, and all the viscera were found to be healthy, there was no ulcer whatever. The abdomen was stitched up and the patient

made a good recovery. He has seen a good many operations for perforating ulcer of the stomach, and he cannot agree that it is so easy a performance as some think, particularly if the perforation occurs on the posterior wall, such an operation could not be successfully carried out with lamp or candle light. Absence of liver dulness is not an essential symptom in the early stage of the disease.

Dr. O'CARROL was of opinion that the sooner the operation is performed after the perforation the better. Some few cases may recover under medical treatment, but he thinks the safer practice is operation. The onset of shock is the call for laparotomy, never postpone interference on account of shock. The gradual and progressive increase of the pulse rate is a valuable sign of perforation in these cases. All the fluid found in the peritoneum should not be looked on as coming from the stomach, the peritoneum itself on the onset of inflammation pours out an abundant secretion. Liver dulness is of little importance as a symptom, and as a rule vomiting occurs more regularly after lesion of other portions of the alimentary canal, than those of the stomach. Symptoms of perforation are very varied; in one of his cases the patient got the symptoms of perforation and recovered; but she developed a systolic bruit, which extended from the epigastrium along the aorta. Five or six weeks afterwards, she returned to hospital and was operated on. The autopsy revealed the presence of an encysted extravasation from a perforating ulcer on the posterior wall of the stomach, which pressed on the aorta.

Dr. PARSONS, whilst warmly congratulating Mr. Tobin on his promptness and successful operations, felt that the physician who was called to a case of sudden illness and recognised a perforation, had a more difficult task than the surgeon who operated, for after all the operation is not a very serious one. In cases of doubt he looks on a diagnostic section of the abdomen as a perfectly justifiable operation. He has found the steady increase in the pulse rate a valuable symptom in these cases, and in his experience the area of liver dulness was diminished, if not at first soon afterwards. The escape of gas found on opening the abdomen he considered one of the most marked signs of perforation. He favoured the removal of the patient to hospital, if the hospital is within reasonable distance and the method of conveyance suitable. The advantages of operation in a properly equipped theatre are enormous. In Dr. Winter's case there was some difficulty in suturing the perforation owing to the sodden condition of the tissues, and eleven days after the patient died of pneumonia. He cannot agree with the suggestion that Trendelenburg's position is a suitable one for the patient suffering from perforation with extravasation, it tends to throw the extravasated material on the lymphatics of the diaphragm and to promote septic poisoning by their absorption.

Sir CHRISTOPHER NIXON, before calling on Mr. TOBIN to reply to the criticism of his interesting and suggestive paper, would just like to say a few words on those cases that leave hospital as cured, as he finds that they are the cases which come back for operation. When being discharged from hospital they have none of the signs or symptoms of the disease, they are practically cured as far as can be made out, yet it is this class that furnishes the surgeon with material. The marvel is, in many of these cases, how they survive the digestion of their food, and that perforation is not more common. A patient came under his care who had lived some years in New York. During that time he had been on several occasions an inmate of the Bellevue Hospital, where he was treated for gastric ulcer. He came to the Mater Hospital very ill and emaciated, vomiting and in pain. As food would not rest on his stomach, he was fed by nutritive enemata and suppositories; after a time he got liquid food. He now craved for a mutton chop and said that it agreed with him in the Bellevue Hospital. He got the chop, eat it with a relish, and the diet was continued. He left the hospital, but soon afterwards came back and died. An ulcer was found near the pylorus, as large as a finger-ring. Why ulcers do not perforate the gastric walls

more frequently, may be explained by the fact that the majority of them are chronic and form adhesions to surrounding tissues; when perforation does occur its site is usually at the cardiac end of the viscus, where the ulcers are acute and speedily perforate the thin walled oesophageal extremity. Gastric ulcers tell us how necessary it is to give patients full and important directions as to their dietary. Of the symptoms discussed, he is of opinion that diminished hepatic dulness is more commonly met with in general peritonitis than in perforation of the stomach.

Mr. TOBIN in reply stated that the object of his paper was to try and induce physicians to bring the surgeon to the patient, not the patient to the surgeon. Not to send a case of perforated gastric ulcer to hospital, but to keep it at home and have it operated on there. He looked on the shock as being occasioned by the extravasation, and to be proportioned to the amount of the extravasation. Of course it may be due to something else, but holding the views he does he thinks the conveyance of a patient to hospital, when all the while more and more matter extravasated is passed into the peritoneum, decidedly injurious. Every one of his cases were diagnosed by the physician in attendance, and he quite agreed that the difficulty in such cases is the diagnosis. He has seen these cases within the past few months and they remain well. The omission of the toilet of the peritoneum was due to the fact that he was addressing the Section of Medicine. In two cases he flushed out the peritoneal cavity with sterilised water, and in one he used a mop of surgical wool on the end of a stick. He looks on the escape of gas on opening the abdomen as a most valuable sign of perforation. An ulcer on the posterior wall of the viscus would, undoubtedly, greatly add to the difficulties, but, happily for us, perforating ulcers are, as a rule, found on the anterior surface. He has operated more than forty hours after perforation had taken place. On admission to hospital, there was a diminution of the area of hepatic dulness in every one of the cases, though the symptom was absent in each one when first examined in their own home. He is in favour of keeping and carrying patients in the Trendelenburg position, when circumstances permit of it.

LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING FRIDAY, APRIL 11TH.

Mr. E. CRESSWELL BABER, President, in the Chair.

Dr. W. H. KELSON showed a case of tumour of the larynx in a woman *æt.* 74, of nine months' duration, apparently springing from the left ventricle. It was rounded and greyish in colour; the cords moved freely. Various members expressed the opinion that it was a cyst.

Dr. ST. CLAIR THOMSON showed a case of Syphilitic Laryngitis, possibly complicated with tuberculosis.

Mr. A. H. CHEATLE brought forward an infant six weeks old with congenital absence of the front of the nose occlusion of the anterior nares. The nasal bones were present, but the framework of the nose in front of the nasal bones was absent. Mr. Cheatle also showed a rhinolith which had been removed from a woman *æt.* 60.

Dr. H. L. LACK showed a new form of laryngeal forceps which were a modification of Mackenzie's well-known instrument. Dr. Lack showed a case of thyrotomy for tuberculosis of the larynx. The operation was performed under the impression that the case was one of epithelioma. The patient was a man, *æt.* 66, in robust health. He was first seen in April, 1901, and on examination an ulcer with raised edges and some surrounding thickening was observed occupying the centre of the right vocal cord. The movements of the cord were considerably impaired. There was a little bronchitis, but no signs of tubercle, and no tubercle bacilli in the sputum. There were no enlarged glands. The diagnosis pointing so strongly to epithelioma thyrotomy was immediately performed, and the patient made a good recovery. Dr. Jobson Horne, after microscopical examination, reported the growth to be tuberculous. Four months later hard, somewhat fixed glands were noticed in the

neck. These were removed, and proved to be tuberculous. The patient had since remained in good health. The removed cord had not been replaced by the usual cicatricial band, and consequently the voice had remained aphonic. Dr. Lack considered the chief points of interest to be (1) the very localised character of the disease with the absence of any signs of tubercle in the sputum or chest; (2) the occurrence of hard enlarged fixed glands in the neck; (3) the good results of the operation, although performed for tuberculosis; (4) the absence even now of signs of phthisis; (5) the absence of the cicatricial band which usually replaced the cord.

Dr. L. H. PEGLER showed a specimen of cystic growth of the septum which had occurred in a male, *æt.* 30. Before removal it was seen occupying the left middle meatus and resembled in appearance a polypus but a distinct attachment to the left side of the septum had been traced by means of the probe. It had been removed by a Mackenzie's snare without difficulty, and proved to be a cyst with a short, hollow pedicle. Three days later the patient wrote saying he had a bad influenza cold, and could not attend hospital. Eight days after the operation he had called in a medical man on account of shivering, pains in the limbs and headache, which symptoms were thought to be due to influenza. Two days later symptoms of meningitis developed, and the patient died fifteen days after the operation. The question naturally arose whether the tumour could possibly have been a meningocele. The specimen had been submitted to Mr. Bland-Burton, who considered that the source of the cyst was a matter of conjecture. Dr. Pegler, supported by Dr. Wyatt Wingrave, thought that the microscopic sections strongly pointed to the fact that the cyst was not a meningocele. The Society, with Dr. Pegler's cordial concurrence, referred the specimen and sections to the Morbid Growths Committee.

Dr. W. HILL showed a case of epidermolysis bullosa with lesions in the mouth and throat, occurring in a woman, *æt.* 87.

Dr. J. DONELAN showed a case of tumour of the right vocal cord, which had formed during an attack of influenza in a man, *æt.* 50.

Dr. ST. CLAIR THOMSON thought it was probably tuberculous.

Dr. FITZGERALD POWELL showed a specimen of a large fibroma removed by intra-nasal methods from the left maxillary antrum in a male, *æt.* 18.

Dr. W. PERMEWAN showed a specimen of laryngeal growth.

Dr. DUNDAS GRANT showed a case of malignant growth in the nose in a male, *æt.* 61, probably of the nature of alveolar epithelioma, microscopic sections of which were exhibited. The question being raised whether the growth might not be one of sarcoma, the sections were referred to the Morbid Growths Committee.

Dr. WYATT WINGRAVE showed a case of paralysis of the left vocal cord in a female, *æt.* 27, and also a case of bulbar paralysis in a female, *æt.* 23.

LIVERPOOL MEDICAL INSTITUTION.

RUSHTON PARKER, B.S., F.R.C.S., President, in the Chair.

MEETING HELD THURSDAY, APRIL 10TH, 1902.

Dr. ARTHUR WALLACE related

TWO CASES OF CÆSAREAN OPERATION

which he had performed on two consecutive days. The first patient was a primipara, *æt.* 39, who had multiple fibro-myomata, one of which, seven inches in diameter occupied the right broad ligament. The pelvis was flattened, its conjugate measuring 2½ inches. The patient's condition did not permit immediate supra-vaginal amputation of the uterus, but this was successfully carried out six months later when patient was two months pregnant. The second patient, *æt.* 27, suffered from syphilis and was also a primipara. The pelvis was flattened and generally contracted as the result of hip disease in childhood; its true conjugate measured 2½

inches. A layer of greenish tenacious material lay between the membranes and the uterus, presumably diseased decidua. The feeble infant developed pemphigus on the sixth day and survived three months. The patient is again pregnant and has elected to have a second examination.

Dr. C. J. MACALISTER read a paper entitled

"A CRITICISM OF THE SANATORIUM TREATMENT OF PHTHISIS,"

in which he emphasised the necessity for inquiry into the after-histories of cases in order to obtain data concerning the permanence of the benefits undoubtedly derived by the majority of patients while under treatment. In his own experience a large number of patients had relapsed after periods varying from months to a few years. His impression from this fact and from the statistics of the German Imperial Health Bureau, was that, while the immediate results were good, the ultimate results were disappointing. He considered that in order to establish permanent benefits to the large majority, who evidently relapse and swell the percentage of those who become incapacitated and die, a percentage which grows in a direct ratio to the number of months succeeding their dismissal from the sanatoria, it would be necessary for them to live in conditions and surroundings similar to those to which they were subjected while under treatment.

Mr. ROBERT JONES read a paper on the

TREATMENT OF INFANTILE SPASTIC PARALYSIS.

The symptoms and pathology of the affection were discussed, and the subject divided into clinical types having reference to the suitability or otherwise of treatment. He maintained that the affection was strictly surgical, and that in suitable cases very marked improvement followed operative measures. In the hemiplegia variety the hand and arm were more seriously involved than the lower limb. If the paralysis was complete, and voluntary relaxation of the spasm impossible, treatment was futile. If the fingers of the affected hand could only be moved in conjunction with those of the opposite side, the results were generally discouraging. Wherever any degree of voluntary relaxation was possible, apart from associated movement on the opposite side treatment was strongly urged. Tenotomy, tendon transplantation, and hyperextension of contracted muscles combined with, and followed by, special exercises were the indications. For the limbs in spastic paraplegia ensections of portions of the adductor longus and brevis, the horizontal fibres of the adductor magnus, the gracilis, and any other structures opposed to free abduction should be practised. Ensections or division of portions of the hamstrings and each tendo-Achillis were necessary. The limbs were then kept in extreme abduction for three months. Mr. Jones described at length the nature of the exercises to be subsequently prescribed, and the methods in which walking should be attempted. A very large number of cases had been operated upon, varying in age from twelve months to twenty years. The benefit resulting was very great, and most children could be made to walk steadily without spasm and for long distances in from twelve months to two years. The classes outside remedial art were the idiot, the microcephalic and the irritable diplegic with incontinence of urine. Immediate paralysis of hands deprived the patient of an essential aid to walking. The effects of tenotomy and mechanical restraint in checking spasm and athetosis were discussed. The treatment of spastic paralysis should resolve itself into a system. It involved operative, mechanical and educational stages. Operations not followed by careful and prolonged after-cure were disappointing. Division of tendons followed merely by massage and electricity was worse than useless. In conclusion, Mr. Jones advocated scholastic institutes for the paralytic children of the well-to-do, where both mind and body could be developed under the scientific auspices of specially trained instructors.

The PRESIDENT noted the laborious character of the treatment, which would demand special hospitals, and specially trained nurses.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD THURSDAY, APRIL 10TH, 1902.

The President, Dr. C. H. WILLEY, in the Chair.

MR. SNELL related particulars of third nerve palsy coming on in a baby when seven weeks old. At birth nothing wrong had been noticed. The child was first seen when the palsy had been present for two weeks.

Dr. JOHN W. MARTIN showed, as specimens, (a) a solid fibroma of the ovary, and (b) a large cystic fibro-myoma taken from a young woman, *et. 24*. These specimens were shown at the meeting of the North of England Obstetrical and Gynecological Society, held at Sheffield, March 21st, and the notes of the cases are given in the report of that meeting published in THE MEDICAL PRESS and CIRCULAR, April 9th, 1902, page 379.

Mr. FAVELL showed a large ovarian tumour, and related a case of hysterectomy for fibroid of uterus.

Dr. WILKINSON read a paper on "Fractures of the Leg," and described a new method of applying a plaster-of-Paris case.

Mr. CONNELL showed specimens illustrating the conditions present in appendicitis, and made remarks on the histology and morbid anatomy of the affection.

Mr. FYE-SMITH opened a discussion on the

TREATMENT OF INFLAMMATION OF THE APPENDIX,

and maintained that the safest course in nearly all cases, whether mild or severe, was to operate as soon as the diagnosis could be made. He thought diagnosis could generally be made within twenty-four hours, whereas prognosis at that stage was very uncertain. Perforation rarely took place before the end of the second day, and abscess did not form till later still, so that by operating during the first twenty-four hours perforation and abscess were forestalled. On the other hand, mild cases were nearly as safely operated on at a very early stage as in the later quiescent stage, and if early operation were the rule we should not meet with the difficult dissections that are now often encountered in operating during the quiescent stage. Nearly all surgeons agree in recommending operation during an attack in severe cases, and after a single attack (if not during it) in mild cases, so that the adoption of the rule of early operation in all cases would involve scarcely any extra operations. The operation, which would almost invariably consist of excision of the appendix, would be a preventive one, and the general result of this early medical treatment would almost certainly be a saving of life and health. Almost the only contra-indications would be the impossibility of obtaining efficient assistance or the presence of such conditions as hæmophilia or severe cardiac or other disease.

Special Article.

INTERNATIONAL CONFERENCE OF THE MEDICAL PRESS.

THE International Conference of the Medical Press, which met in Paris in July, 1900, was intended to be the prelude to periodical congresses having for object to bring the members of the medical press throughout the world into touch with each other. So comprehensive a scheme requires considerable powers of organisation to make it a success, and subsequent events rendered it desirable to arrange for a meeting of delegates before proceeding further. Great difficulty was experienced in defining the precise objects of the association, and a very pronounced divergence of views made itself manifest, so much so, indeed, that at one time the project seemed likely to fall through. Thanks to the energy of a group of foreign pressmen it has escaped shipwreck, and a meeting of delegates was convened and actually took place at Monaco early this month under the patronage of the Prince of Monaco, who is well known as an enthusiastic supporter of scientific and literary movements. There exists in the Principality a medical society which is itself a sort of international association, since the medical men practising there belong to many different

nationalities. The President, Dr. V. Godineau, is a Belgian; the Vice-President, Dr. B. Price Mitchell, is an Englishman; and the General Secretary, Dr. H. Guimbail, is a Frenchman, while the other members comprise representatives of the Italian, Swiss, German and Austrian nationalities. The Prince offered every facility for the meeting, and contributed generously to make it both practical and entertaining. The object of the meeting of delegates was to ascertain whether a sufficient common ground of agreement could be found so as to establish definitely an International Medical Press Association, to elaborate a scheme for such an association, and to arrange for a general congress at which the draft scheme could be discussed and confirmed. These various objects have been attained. A set of rules was adopted, and it was decided to arrange for an International Congress of the Medical Press to be held a few days previous to the meeting of the International Medical Congress which is to assemble at Madrid in April of next year. Full details of the debates and resolutions will be published in the course of a few weeks, when those who are interested in the movement will be enabled to take cognisance thereof, and to decide upon their course of action. The delegates seem to have had a very good time of it, thanks to the hospitality of Prince Albert, whose domain lends itself so admirably to the festive side of such meetings, and the delegates availed themselves of the opportunity afforded them of inspecting the Oceanographic Museum and the various apparatus and appliances devised by his Highness for carrying on the marine investigations with which his name is intimately associated.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, April 20th, 1902.

HUMAN ACTINOMYCOSIS IN FRANCE.

At the Académie de Médecine, M. Poncet read a paper on actinomycosis in man, in France, in which he said that within the last few months he was able to collect twenty-one new cases published by different authors. The affection was met with in nearly every case (eighteen) on the face or the neck. In each case the clinical diagnosis was confirmed by the microscopical examination of the pus. To these twenty-one cases he would add eight others, noted by a friend of his in Paris, which, added to all those published, gave a total 146 cases of human actinomycosis known up to the present in France, of which seventy-nine were localised in the face and neck and sixty-seven in the viscera.

As regarded the prognosis of that affection, M. Duvaun, a military surgeon, was able to procure information on the final lot of 257 patients, both at home and abroad. By these documents it was found that the mortality, which was only from 2 to 3 per cent. in the cutaneous forms and 10 per cent. in the cervico-facial forms, rose to 30 per cent. when the malady was deeply situated in the temporo-maxillary region, to 65 per cent. in abdominal actinomycosis of intestinal origin, to 85 per cent. when localised in the thorax, and 100 per cent. when the liver or cerebro-spinal system were attacked. The gravity of the visceral forms arose from the difficulty of treating due to the extended infiltration of the malady.

ETHER v. CHLOROFORM.

M. Renaut, in alluding to the recent discussion on the administration of chloroform in cases where the patients were suffering from a cardiac lesion, said that chloroform affected the kidneys, and where these organs were diseased, as was frequently the case in cardiac affections,

ether, which had no action on the renal bodies, should be preferred. All points considered, the latter anæsthetic was always inoffensive, and should be substituted for chloroform generally.

HYPERTROPHY OF THE PROSTATE.

At the meeting of the Société de Clinique M. Potheral read a report on the treatment of hypertrophy of the prostate by resection of the vas deferens. Of four patients treated, one succumbed a few days after the operation, two were much relieved, while the fourth remained in *statu quo*. In his opinion the operation had but little efficacy against hypertrophy of the prostate.

M. Leguen considered that the operation procured only a temporary improvement, and that prostatectomy was much superior.

THE GRIPPE.

Dr. Bourget treats with constant success influenza by the following aromatic liniment:—

Salicylic acid, 3ij;
Salicylate of methyl, 3ij;
Ess. of eucalyptus, 3j;
Ess. of sage, 3ss;
Camphorated oil, 3j;
Spirit of juniper, 3iv.

The liniment is rubbed into the chest of the patient and on the back, after which the bedclothes are drawn up to the chin. The heat of the bed facilitates the evaporation of the aromatic ingredients and the absorption of the salicylic acid, which can be found in the urine at the end of half-an-hour. A considerable improvement in the condition of the patient rapidly follows.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, April 19th, 1902.

At the Dermatological Society, March 4th, Hr. Lessen reported a case of

SEVERE POISONING AFTER INJECTIONS OF SALICYLATE OF MERCURY.

The patient was a woman, æt. 36, who, having undoubted syphilis, had received three injections of solution of mercury salicylate at intervals of about five days. As a precaution the surgeon had injected at first only 0.05 gramme, and afterwards 0.1 gramme, the usual dose. As diarrhoea supervened no further injections were given and opium was administered. Three weeks after the injections a typical mercurial rash appeared. The patient was then sent into the Charité Hospital. The exanthem healed with exfoliation of large scales. The diarrhoea ceased after enemata of starch and tannin. The urine showed $\frac{1}{2}$ per cent. of albumin. On February 27th (about three weeks later) a large necrotic piece was expelled from the vagina, which was proved to be the whole mucous surface of the uterus and vagina. It appeared that there was a wide communication between the rectum and the vagina. At the time of reporting the patient's condition was so bad that an unfavourable prognosis must be given. The patient must have had an idiosyncrasy in regard to mercury. He thought in future that smaller doses should be administered.

Hr. Lippmann uttered a warning against the use of insoluble salts of mercury.

Hr. Jaffa reported a fatality after a second injection

of salicylate of mercury. After the second injection bloody stools appeared and the patient died. It appeared that intoxication had taken place for the reason that, on account of paralysis the patient could not get rid of the mercury excreted. In mercurial diarrhoea no efforts should be made to check it.

The *Berl. Kl. Woch.*, 5/02, has a report on an

ARTIFICIAL ŒSOPHAGUS,

by Dr. Speigel. The apparatus consists of a tube connected above with an opening in the œsophagus above the stricture and below with the gastric fistula. A small roller glides over the tube, so that on downward movement the tube is pressed flat, and by upward movement the flattened tube again opens out. By downward movement a vacuum is created in the tube through which nourishment is sucked downwards. By repetition of these upward and downward movements the food that the patient has masticated, tasted and swallowed is passed into the stomach. Such an apparatus will find its use mostly in cases of stricture from swallowing of caustics, and not in cases of carcinoma.

At the Medical Society Hr. Rosenheim spoke on

IDIOPATHIC DILATATION OF THE ŒSOPHAGUS.

He said the affection was much commoner than was supposed. He had seen nine cases, five during the last two years. Recognition of the disease was very important, as when it had existed for long it was incurable, but if treated early enough it could at least be materially improved. As far as his observation went the sufferers were mostly young men. Trauma was given as the original cause, a blow on the chest, or the swallowing of too hot or too large mouthfuls. It was certain that for the affection to arise two disturbances of innervation were very important: (1) atony of the œsophagus itself, and (2) cardio-spasm. Whether both together were necessary was at present doubtful, but he believed that either by itself might lead to the condition in question.

The diagnosis was at first difficult for the reason that the disease began with ill-defined gastric symptoms, lasting for years and defying all treatment until finally the difficulty in deglutition attracted attention to the œsophagus. Three patients complained for years of gastric cramps, even when both stomach and œsophagus were empty. Occasionally attacks of shortness of breath came on which were not necessarily in immediate connection with the condition of the sac as to fulness, but came on even when it was only moderately full and remained absent when it was quite full. In any case the only means of cutting the attack short is to wash out the sac. Patients are frequently disturbed in the night by shortness of breath and coughing; as in the horizontal position the contents of the sac run over and pass into the larynx, but this might happen even when the position is erect. There are also fetid belching, heartburn, eructations, nausea, vomiting, and similar ill-defined symptoms. In passing a sound the condition is sometimes determined by feeling the sound to move unusually freely in the œsophagus, but it is more typical when fluid escapes even before the tube has reached the stomach, the material containing no hydrochloric acid and no products of digestion. The differential diagnosis between diverticulum and dilatation is difficult, but of no practical therapeutical importance. The prognosis as to complete restoration is, in the case of a large sac, unfavour-

able. If the disease is not of long standing, not more than one or two years, a good deal of improvement may be hoped for.

In treatment it must be borne in mind that the sufferers are mostly exhausted, neurasthenic people, that the disease is, therefore, a partial symptom of the neurasthenia.

Treatment is symptomatic, but, properly carried out, of unmistakable benefit to the condition. Emptying and washing out of the sac are important. Washing out with carbonic acid acts favourably on the atony. Of medicaments that act as deodorants or disinfectants, nitrate of silver was the best, either by washing out with a 1 or 2 per cent. solution, or swabbing the walls of the sac with a 10 per cent. solution. As regarded diet only general hints were given. In cases of cardio-spasm it was dangerous to force the sound through. Rest in bed, opium, and regulation of the diet were better. In case of narrowing of the cardia a fine sound was to be introduced, with a hollow ball at the end. When through, this should be filled with water and withdrawn. When this was done a few times, further progress could then be made.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, April 19th, 1902.

COSMETIC TREATMENT OF SADDLE NOSE.

At the "Gesellschaft der Aerzte" Fein exhibited a case of saddle nose which he had dealt with by Gersuny's method of injecting paraffin subcutaneously. Fein recommends the commercial paraffin known as white vaseline, melting at 40° Cent. or 104° Fahr. It should be injected in neither too fluid nor in too hot a state, and, as in the present case, at intervals of five or six or eight or ten days each. It may be injected at the root of the nose in the middle line or at the tip.

Matzenauer remarked that this was only a temporary device, the improvement not lasting more than two years when it had to be repeated.

Ehrman thought that recurrence of the flattening might be prevented if the injections were rigidly kept to the middle line subcutaneously, and not under the muscle as was sometimes practised.

Weil said he had always obtained excellent results from paraffin melting at 40° Cent.

VOLVULUS.

Büdinger exhibited a young woman, æt. 24, on whom he had performed laparotomy, last January, for an unusual twisting of the bowel. About the beginning of November she had an abortion after heavy stair cleaning. About the middle of November great pain in the bowel, with cramp and vomiting set in, which continued to the middle of January. The diagnosis was pelvi-peritonitis with volvulus. Laparotomy confirmed the diagnosis, as the small bowel was twisted 180 degrees, causing the left tube to adhere to the base of the mesentery. After dividing all bands and replacing the gut she recovered rapidly.

MALFORMATION OF LEFT TROCHANTER.

Neurath showed a child, æt. 9 months, with a congenital defect in the upper part of the left femur. The Röntgen rays showed absence of the trochanter and neck of the femur, the epiphysis of the head of the bone

being directly implanted in the diaphysis. He considered this malformation to be amniotic in origin.

Weinlechner was inclined to attribute the malformation to premature adhesion of the epiphysis.

TRANSPLANTED KIDNEY.

Ullmanshowed a dog (which he had already shown at a previous meeting) with the kidney totally transplanted into the animal's neck, and the animal appeared to be in excellent health.

TALMA'S OPERATION FOR HEPATIC CIRRHOSIS.

Kretz showed several preparations of the liver which he had injected, showing degenerated areas in the parenchyma, while capillary anastomosis was maintained with the vena cava. Bielka's experiments on dogs, and Eck's fistula teach us that death may ensue when the normal liver is operated on, death being probably due to poison from the bowel.

Talma's operation is contra-indicated where there is slight icterus, alimentary glycosuria, reduction in the urinary constituents or an insufficiency of resistance in the liver. On the other hand, the best results can be obtained by removing the sclerosed area of the liver by operation.

PHYSICAL TREATMENT OF SKIN DISEASES.

At the "Doctoren-Collegium" Schiff read a long paper on the more recent methods of treating skin diseases and he exhibited a large number of cases to demonstrate his point. The first series were "cosmetic," or epilation for hypertrichosis, which can also be done by the Röntgen rays. Epithelioma and lupus could now be treated as cases in which an operation was impossible. He showed a case of favus that had persisted for two years, and another of acne follicularis faciei ulcerosa that he had treated by the Röntgen rays and unipolar static electricity.

The advantages of the Röntgen rays over Finsen's treatment are:—(1) Finsen's apparatus is expensive; (2) Röntgen rays require a shorter time of application—ten to fifteen minutes—while Finsen's requires one to two hours. The whole duration of the treatment under the Röntgen rays does not exceed two months, while Finsen's treatment covered as many years, even with eighty ampères. He is inclined to recognise three factors in the Röntgen treatment, neither of which will by itself effect a cure:—(1) physiological, (2) the action of the glass, (3) the electro-chemical action in the production of ozone. To prevent loss it is better to enclose the tube in a box lined with lead, with one side open to emit the rays. This isolation is an economical method of using the rays.

Franklinisation is a form of electricity with a double kind of action according to which side of the jar is discharged, and is thus described as the "unipolar" form of treatment. A discharge from the inner surface causes hyperæmia, and therefore hyperæsthesia; while the discharge from the external surface produces anæmia and therefore hyperæsthesia, and often relieves the pain associated with many skin diseases and the intolerable itching caused by many cutaneous affections. He related a painful case of hæmorrhoids in which he operated with the most beneficial results by the simple application of the electrode to the anus. According to several French authors, ozone is freely liberated and believing that this gas is one of the factors in the treatment of all cutaneous diseases, he has devised an

apparatus whereby this gas is mixed with carbonic acid gas and applied with the current through a trumpet shaped electrode.

BACTERIA AND RONTGEN RAYS.

Rieder finds that twenty to eighty minutes are necessary to kill microbes by Röntgen rays; but when reset in an inflamed tissue, they disappear in a much shorter time.

The Operating Theatres.

FRENCH HOSPITAL AND DISPENSARY.

OPERATION ON THE PREPUCE.—Mr. DE MERIC operated on a man, *st.* about 25, who, about seven weeks previously, had contracted syphilis. The patient had been first treated at another hospital where the prepuce had been freely slit up, as, from his description, the foreskin had been very tight, and a considerable amount of discharge had come away through it. When seen at the French Hospital the penis presented a very unsightly condition, the two halves into which the prepuce had been divided being very much hypertrophied, and hanging on each side and below the glans penis. On the inner side of the right mass was a very typical primary sore in a state of cicatrisation; the sore was slightly raised above the skin and mucous membrane, and presented an even, flat surface, which secreted a very slight discharge. The glands in the groin felt like marbles, and there was a secondary rash on the abdomen, chest and arms. Mercury, of course, was administered in the form of the green iodide; after the sore had nearly cicatrised, presenting a surface of less than the size of a threepenny-piece, the man was put under an anæsthetic, and Mr. de Méric trimmed up the prepuce, excising the two pendulous masses with forceps and scissors, the sore being necessarily included. After doing this he brought the mucous membrane and skin into apposition by means of sutures. Mr. de Méric said that the case was interesting because it demonstrated that there was no danger in slitting up the prepuce if the surgeon can be absolutely sure that the sore under it is a syphilitic and not a soft chancre, there being in the former a certainty that the edges of the wound will not take on the characters of the sore, and become themselves sores, which would be the case were the slight operation to be performed when simple (or soft) chancres were present. He pointed out that in the present case the prepuce had been slit up at another hospital, owing to the extreme tension produced probably by the infiltration and hardness of the sore with, in all likelihood, a co-existing balanitis, but whoever slit up the foreskin on that occasion must have felt a considerable uncertainty with regard to diagnosis, for, if a syphilitic sore, as it evidently was, had been diagnosed, no harm could have resulted in performing complete circumcision, indeed it might have gone towards demonstrating the fallacy of imagining that if a syphilitic sore be excised, no secondary symptoms will appear, but the foreskin had evidently been left as it was on the supposition that perhaps the single chancre exposed was a soft sore, which was very improbable. M. de Méric added that under the circumstances he waited till the sore had nearly healed, as he could then cut wide of it, and not irritate it.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d. Half Page 22 10s. 0d., Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 23, 1902.

A MEDICAL DEGREE FOR DIPLOMATES OF THE LONDON CONJOINT BOARD.

THE much-debated question of enabling the diplomates of the London Conjoint Board to assume the title of "doctor" has entered upon a new and interesting phase. The Committee of Delegates, having fully considered the subject as presented to them by a memorial signed by upwards of six hundred teachers, practitioners, and students in medicine, advocating the amalgamation of the two Colleges into one Royal College of Medicine for the purpose of granting degrees in medicine and surgery, unanimously passed resolutions approving the idea and affirming that the curriculum of study and the examinations required for the conjoint diploma are equal to those of most Universities, and the Committee add that, should the two Colleges approve these resolutions, means could be found for giving effect thereto. This is news indeed! It may be assumed that the Committee, which is composed of delegates in close touch with the corporations they represent, feel reasonably certain of the reception likely to be accorded to these resolutions so that we may look forward to the realisation of this project. The immediate effect of the *mise en vigueur* of the project will unquestionably be a depreciation of the esteem in which, with more or less reason, degrees in medicine have hitherto been held by the public. Admitting that the medical curriculum of the Colleges is fully equal to that of all but a few degree-conferring bodies, the fact remains that from the point of view of general and scientific education no such equality exists, and nothing is mentioned of any intention to improve on the present standard at present required by the Colleges. Unless this be done we should positively regret to see this unblushing instance of down-

ward competition pass into the domain of accomplished fact. Moreover, the example set by the London Colleges is certain to be followed by the other licensing corporations, and there is no obvious reason why the licentiates of the Society of Apothecaries, in London, and of Apothecaries' Hall, in Dublin, should be left out in the cold. Their curricula, at any rate, are equal to those of the Universities in so far as medicine is concerned, and their preliminary examinations are virtually the same as for the London Colleges. It comes to this, that should this scheme be realised the doctorate of medicine will become the "pass" degree, and not, as previously, the presumptive indication of a higher degree of culture. True, the source of the degree will remain to enable the curious to distinguish between the various titles, and that is a point worth bearing in mind. It must be admitted, on the other hand, that the diplomates of the various licensing corporations have come to occupy an invidious position in the medical world. They are, as one might say, neither fish, flesh, nor fowl. The public have never reached that standard of intellectual development which would enable them to distinguish between a medical practitioner and an M.D., consequently all medical men alike, not to speak of chemists and dentists, are universally dubbed "Dr." by their patients and their patients' friends. Moreover they have suffered in temper and dignity by the superiority affected by graduates of Universities even such as ought not, in conscience, to arrogate to themselves any such claim. Lastly, there is much to be said in favour of uniformity of medical title, though we should prefer to see the licensing bodies level upwards and not downwards in any changes initiated by them.

THE "DANGEROUS" OCCUPATION OF BARMAIDS.

A RECENT decision of the Glasgow authorities henceforth to abolish female labour at public-house bars has aroused a good deal of comment throughout the United Kingdom. As the matter is one of considerable importance to a large industrial class its health aspects are to that extent worthy of consideration in the columns of a medical journal. The ill consequences attached to the occupation in question are clearly of two kinds, namely, moral and physical. With the moral aspect of the calling we are not directly concerned, and it may safely be left in the hands of the philanthropist; but the physical results appear to merit consideration from more points of view than one. Barmaids are, for the most part, young women who are employed in a quasi-domestic capacity, which places them outside any of the ordinary rules as to length of hours of labour. In other words, they represent an unorganised branch of female labour, and are consequently at the mercy of their employers in much the same way as shop girls and domestic servants. The long hours of labour to which the average barmaid is subjected constitute a standing disgrace

to the manner in which the retail drink traffic of the United Kingdom is conducted. On all hands the tendency is to shorten the hours of labour, and the "Eight Hours' Bill" for miners has now come well within the purview of practical politics. There is no Eight Hours Bill for domestic servants, who are often on duty for sixteen hours daily for weeks together. The barmaid is on precisely the same footing, except that her work is even more laborious, inasmuch as it frequently involves standing for twelve or fourteen hours out of the twenty-four. To this may be added the fact that the sleeping accommodation is in most instances very imperfect, and the food none of the best. The result of this incessant strain and unwholesome environment upon young women must necessarily be bad, and the tale of damaged health is often recorded in unmistakable characters upon the anæmic and prematurely aged faces of girls engaged in this "dangerous" occupation. Indeed, it has always been a matter of surprise that nothing should have been attempted in the direction of regulating the labour of those engaged in this branch of commerce, both men and women. This, in truth, should occupy a prominent place in the much-needed reform of the drink traffic in this country. The principles involved are simple. It is alleged, on evidence that may be readily collected and examined, that there exists a class of workpeople whose health is damaged by the onerous and unfair conditions of the trade in which they are engaged. In the case of women workers in the potteries and in the match trade Parliament has interfered to protect them from the terrible effects of lead and of phosphorus poisoning. It may be questioned whether the total loss of life and damage to health is a whit greater in the two trades mentioned than it is among the barmaids by reason of the stress of occupation and associations. Barmaids are nearly all young women, presumably because personal attractiveness has a commercial value to the employer. It would be interesting to learn what becomes of barmaids in later life. Indeed, there is pressing need of authentic information bearing upon all the facts connected with this class of domestic service. A Royal Commission might be occupied with matters of less practical importance, and whatever the result of its inquiries, an investigation of that kind could not fail to provide valuable data for future guidance. Members of the medical profession would be able to afford a mass of testimony as to the sickness and mortality prevalent among this particular section of the community. A perfunctory examination of the hospital records of any great town would certainly furnish material for serious reflection by demonstrating to some extent the relative sickness and mortality statistics of barmaids as a class who had come under treatment. The alternative to female labour clearly suggests the question why men should preferably be subjected to such unwholesome conditions of labour. Under existing circumstances men would doubtless sustain less harm than women, but the fact remains that radical alterations are imperatively called

for at the hands of the Legislature with the object of regulating the hours of labour of all persons employed in public-houses, regardless of sex. The mortality amongst publicans' servants is simply appalling, and it is the duty of preventive medicine to inform the mind of the progressive legislator on all such points. The movement in Glasgow is to be commended inasmuch as it has drawn public attention to the disabilities and the sufferings of an important class of female workers.

Notes on Current Topics.

The Hairpin in Surgery.

THE humble but not always inoffensive hairpin appears to be a surgical implement with a wide sphere of usefulness in the hands of the dexterous surgeon who relies more upon his skill than upon the perfection of his armamentarium. Dr. Torrance Rugb, of Philadelphia (a) waxes eloquent in respect of the numerous purposes to which the hairpin can be applied. It is always at hand, it is of convenient size for manipulation, it is readily sterilised, and it can, in virtue of its flexibility, be twisted to any desired shape. It can be had in a practically unlimited number of forms, in regard to size, shape, stoutness, flexibility, rigidity and so on, and each variety is adapted for particular operative conditions. In its natural shape the finer varieties can be used for pinning on gauze dressings, to remove concretions, or foreign bodies from a sinus, natural canal or opening, and as a blunt curette for the removal of superabundant granulation tissue, &c. For diagnostic purposes its points, being adjustable by bending, can be turned to account as an æsthesiometer, for measuring the acuity of tactile sensation, and when that has been done the same instrument, turned upside down, may take the place of a catheter for the female bladder. Obviously, the hairpin lends itself admirably for passing beneath a wounded artery with the object of making the base of a figure-of-eight ligature, or by placing the vessel between the prongs it can be made secure merely by twisting them to the required degree. Straightened out, the hairpin makes a very good substitute for a probe, and if a little cotton be twisted round one end medicinal applications can be made to diseased surfaces. With it we can wire bones together in the absence of silver or platinum wire; heated, it can be used for the actual cautery, either punctate or linear, or on the flat. As a harelip pin it "yields to none," and it has even been made use of as a sound for detecting vesical calculus in children. A hairpin is capable of rendering invaluable service in the removal of foreign bodies from the ear, nose, &c., by using the curved end, and, when suitably bent, also as a tenaculum. When bent or twisted the number of things for which the hairpin can be used is limitless—as a retractor, as an aneurism needle, *vice* a tracheotomy tube, and to promote drainage. The edges of a wound can be approximated and kept in apposition

(a) *American Medicine*, April 5th, 1902.

by placing the hairpin so that the prongs on either side are parallel with each edge. Obviously it would be preferable to employ the instrument *ad hoc* were it to hand, but the best surgeon is unquestionably the most resourceful, and as the hairpin appears to be capable of replacing every instrument save the scissors and the scalpel there is likely to be a "slump" in dressing-cases.

The Illness of the Queen of Holland.

THE position of the physician who finds himself in charge of an illustrious patient in the early stage of typhoid fever is necessarily a trying one. He may suspect the nature of the disease from the outset; indeed, after the first two or three days he may regard it as approximately certain, but, in the absence of the characteristic symptoms, prudence obliges him to abstain from even a tentative diagnosis. This trying and anxious stage lasted some days before the physicians in attendance on the young Queen of Holland could venture on a positive diagnosis, but this became possible towards the end of last week. History shows that the highest social position affords no protection against typhoid infection although it is pre-eminently a preventable disease. The crisis through which our own King, then Prince of Wales, passed, now a quarter of a century or more ago, proved that wealth and position do not ensure attention to certain elementary hygienic precautions, in the absence of which infection is rendered possible. So far, there is nothing in the published reports of a nature to excite anxiety, but some time must elapse before any trustworthy opinion can be formulated as to the probable severity of the attack. This young and interesting sovereign will have the heartfelt sympathy of all, and we only voice the general hope that her youth and normally strong constitution will enable her to withstand the attack.

The Medical Inspection of Board Schools.

SIGNS of the times are not wanting to point to the coming of the daily medical inspection of all Board schools. The most powerful agency at work has, in all probability, been the immense spread of diphtheria during recent years, a disastrous wave that can be satisfactorily explained only by the increased aggregation of the children of the community following the development of the School Board system. Sooner or later the whole question must be handled decisively by the school authorities in all parts of the United Kingdom. Partial medical control has been established in a few places, but for the most part there is absolutely no system whatever aiming at the exclusion of infectious scholars from contact with the healthy school children. It is obvious that a few casual visits of a medical inspector would be of little use. What is wanted is a daily visit by an experienced man who would be prepared to devote several hours to the medical examination of all scholars noticed to be ailing or whose parents desired an inspection. In this way many cases of diphtheria, scarlet fever, measles, and other communicable

maladies might be excluded. Many infectious eye diseases would also be detected, to say nothing of ringworm, which is now simply flourishing in the Board schools as weeds spread in a neglected garden. Mr. Balfour's new Education Acts would deserve more support at the hands of the medical profession if they made some attempt to deal with the hygienic aspects of school life.

Street Music and Seaside Invalids.

IT seems extraordinary how any health resort can in its own interests permit piano-organs and other itinerant music to parade their streets. Take, for instance, a place like St. Leonards, which is more or less full of invalids all the year round, and where street music seems to have an equally evergreen season. Quiet and restfulness are often more than half the battle, not only in the actual combat with disease, but also during the slow and tedious stages of recovery. How are those healing and most invaluable therapeutic conditions to be secured? They are not to be bought at the chemist's, but can be to a great extent provided by prudent bye-laws excluding the whole race of roving musicians from the neighbourhood. From St. Leonards a medical correspondent writes telling of two patients who were disturbed daily by the sudden discordant outburst of a piano-organ. In one case the illness was of a critical nature, and recovery might have been said to hinge almost entirely upon procuring a good allowance of sleep. Of what use is it for the anxious physician to prescribe narcotics as a last resort if his patient, having sunk to sleep, is liable to be awakened any moment by a grinning Italian mendicant? At Bexhill, which is close to St. Leonards, they have been wise enough to exclude all street musicians, and to confine their musical entertainments to a band in the winter garden. Surely the whole question is worthy of careful consideration at all seaside and other places where invalids do congregate. In many such towns, however, the interests of the visitors appears to be the last thing that are looked after by the Corporations. That is shown by the bad drainage and bad water supply often found at the seaside, to say nothing of the inadequate provision for isolation and disinfection in infectious diseases.

An Ingenious Fraud on Medical Men.

THERE seems no limit to the ingenuity of misguided persons in their endeavours to obtain money, or its equivalent, from confiding medical men. The last bid for unpopularity in this direction is for a person to cycle to the house of a well-known practitioner, ostensibly for the purpose of engaging him to attend the wife at her confinement, and then to raise a small loan in the absence of the purse which has inadvertently been left at home "on the piano." It has been suggested by a newspaper commentator that any medical man who recognises this delinquent might, before handing him over to justice, invite him with simulated cordiality to partake of some light refreshment, which in the present state of medical science

it would not be difficult to render offensive. The only drawback to the experiment is that magistrates are apt to regard it as of the nature and quality of an assault, indeed, we can recall the disagreeable adventure of a practitioner in the west of London some years ago who, having succeeded in laying hands upon a small but sinful youth who had, with malice aforethought, rung the surgery bell, gave him the option of swallowing a nauseous powder or being handed over to the police. The youth chose the former alternative, but his inappreciative parents summoned the practitioner, who was fined for assault, and the magistrate added injury to indignity by refusing a summons against the lad for assaulting the doctor's door bell.

Spectacles and Failing Vision.

A POPULAR French lecturer, referring to his experience in the United States, observed that he regretted to have remarked so many of his audience wearing spectacles, adding that they had evidently worked their eyes so hard as to cause their sight to fail, and he concluded by urging that they should not allow their love for knowledge to damage their vision. The lecturer, with all his acumen, only re-edited a popular fallacy. We are familiar with the reluctance which many people manifest to resorting to spectacles at a time when age has rendered their use necessary to comfort, under pretext that it makes it impossible to do without them. It is obvious, or should be, even to the non-medical mind, that spectacles are aids to vision and by reducing the strain on the organs of sight tend to maintain and prolong functional activity. Refusal to make use of glasses does not modify or improve imperfect vision, and such refusal is based on mere prejudice. The fact that the more studious nations make most use of spectacles is due to the fact that it is not until the eyes are employed persistently for near objects that any defect is perceived to the extent of becoming uncomfortable. Eyes which are serviceable enough to guide a plough or sweep a street may prove inadequate to close study or fine manual labour. It is a pity that intelligent men should thus lend their influence to bolster up a prejudice which in the long run is productive of much discomfort and no small amount of mischief.

Hospital Statistics.

OUR contemporary, *American Medicine*, makes some interesting observations on the figures published by the State Board of Charities bearing on the number of in-patients at a particular institution therein referred to. It is stated that during the year 1900 this hospital admitted no less than 9,308 new patients. Now, the total bed accommodation for patients in that institution happens to be 292, and the average number of beds occupied during the year was 194. Taking the average stay in hospital of each patient to be eighteen days, an estimate which some pains have been taken to verify, the figures seem to show that at least 5,636 persons must have slept two in a bed; indeed, if, instead of the total bed capacity, we take the

average of bed days, as reported, it will be seen that a large number of patients must have slept three in a bed! Our contemporary naturally asks how this can have come to pass and suggests the following alternative explanations—either the average stay in hospital must have been less than eighteen days, although in other hospitals the average varied from twelve to twenty-one days, or the figures must have been falsified in order to influence the allocation of State funds. As the latter hypothesis is, of course, inadmissible we are thrown back upon the supposition that several persons must have slept in a bed. If so it may be remarked that disease, like poverty, makes strange bedfellows. It would be interesting to apply this method of investigation to some of our own statistics, and perhaps those of our readers with a taste for calculations will undertake the task and communicate to us the results.

The Cost of Revaccination.

As we anticipated, boards of guardians are growing restive at the formidable bills which they are called upon to pay for the services of public vaccinators, owing to the "rush" for revaccination which has taken place in consequence of the prevalence of small-pox. It must be admitted that the figures are calculated to make the mouths of other than public vaccinators water; witness one quarterly bill for nearly £1,500 and others varying from £500 to £700. Of course, if properly considered, these amounts are in no wise excessive. The fact is that public vaccinators have been making up for lost time and have had to catch up the arrears of twenty years and more in the short space of a few months. They have had to work early and late, and have in many instances broken down in health under the strain. Although we cannot help thinking that public vaccination might be better carried out by some other than the present system, and although public vaccinators have caused much heartburning by the unjustifiable way in which they have pushed themselves on public notice, to the detriment of the general practitioner, we cannot honestly say that they have not earned their harvest of fees, or that the sums paid for vaccination are other than reasonable.

Disinfection a Farce at Brynmawr.

THE Official Report of the Local Government Board inspector upon the pollution of Llanelly and neighbouring villages by the Brynmawr Urban District Council's sewage works, has recently been issued. The document discloses wholesale pollution of the water supply of a district with a population of 3,077 persons, among whom enteric fever has been prevalent for many years. The Commissioners recommend proper drainage and water supply to the various villages and that the Council's sewer should be made watertight. They add the caustic and scathing comment that the fact has been brought home to them in the course of their inquiry that, had the recommendations made by Dr. Gwynne Harris in

1872 been carried out, "many deaths and much suffering would in all probability have been prevented." They point out that the only attempt made at disinfection is a "farce." In one house where a woman lay sick of typhoid fever some similar fluid had been supplied in a bottle labelled "Scotch Whiskey." There was nothing to indicate that the bottle contained a disinfectant, or that the liquid was not intended for internal use. To place chemical disinfectants without distinctive labels in the hands of a rural population is clearly to court calamity. It appears that in this modern plague-spot no attempt is made to abate obvious nuisances existing on premises where infectious disease exists or has existed. All this reads like the description of some mediæval village where sanitation was unknown and filth diseases rampant. It is surely time that the Brynmawr local authorities were brought sternly and sharply to a sense of their responsibility in dealing with the lives of the population under their care.

The Seasonable Clothing of Children.

THE clothing of children is at all times a matter of prime importance in the region of domestic medicine. It may perhaps be to some extent doubted whether medical men, as a class, are sufficiently alive to the bearing of this detail of environment when called upon to advise in the care and management of children. In a climate so treacherous and variable as that which prevails in these northern islands the proper adjustment of the clothing of children to the variations of season really becomes a fine art. The first warm day in spring is only too often the signal for throwing off the warm winter clothing and letting the child go forth arrayed in muslins and other summer finery. The usual result is contact with an east wind round some sharp corner, and the familiar "cold" which, thus started, may last for many weeks or even lay the foundation for more serious mischief. A knowledge of matters of this kind is simply invaluable to every medical man who is called upon to deal with children. The principles of the food and the clothing of children might well be taught in our medical schools, where a short course of lectures by a competent lady expert would be of infinitely more value to the future practitioner than many an advanced course of practical physiology, or of other erudite subjects which can be of no practical use to him in after life. To be able to apply delicate physical tests to disorganised nerves may be interesting to the medical attendant, but the patient's friends would naturally prefer some information as to the underlying cause of the trouble, which, in the case of children, may often be traced to errors in diet or in clothing.

THE death is announced of Dr. Alexander McGregor, formerly of Aberdeen, but lately of Queen Street, Berkeley Square, Physician to the North London Hospital for Consumption and Diseases of the Chest. Death was sudden, and is attributed to angina pectoris.

Professor Whitla's Gift to the Ulster Medical Society.

THE members of the medical profession who live in Belfast or in other places throughout Ulster are at the present moment, and will be for many future generations, under a very considerable debt of gratitude to Professor Whitla for his generosity in presenting to them the proposed Ulster Medical Institute, the foundation stone of which was laid on April 13th. The great advantage which such an institute will offer to medical men does not require to be demonstrated. It will—as a speaker at the foundation ceremony said—prove of value not only to the medical profession at large, but indirectly to the poorest member of the general public, inasmuch as it will afford opportunities for the interchange of ideas, and consequently tend to the promotion of the higher intellectual standard which constant intercourse with our fellow-men brings about. Might we venture to hope that its foundation will also lead to the creation of a more cosmopolitan spirit in the Ulster Medical Society, and of a spirit which will lead it into a more open communication with the extra-Belfast members of the medical profession. It always appears to us to be the greatest pity that the Ulster Medical Society does not bring itself more into prominence. At present, an occasional odd quarter-column notice in a contemporary is the only link between it and the general body of the profession, and we do not think that the society can attribute this to lack of opportunity. Ireland is a small country, but it has always been well in the van in the advance of medical science. Why, then, should the Ulster Medical Society not only hide their light under a bushel, but even repel all attempts to lift the veil with which the bushel is covered.

An Indecent Advertisement.

A SHORT time ago a most extraordinary advertisement appeared in the pages of a well-known medical journal, published in America, in which two female nude figures were portrayed. One of these represented a case of elephantiasis; the other was that of a well-made woman of attractive appearance. If the pictorial part of the advertisement was objectionable, not less so was the letterpress which accompanied it. We do not intend to convey the impression that the wording of the notice was intentionally such as to allow of suggestiveness or indelicacy. That the advertisement appeared to many to be so indelicate and improper as to lead them to severely criticise it, indicates that the pictures alone were not the only or indeed the principal cause of complaint. They would have called for no adverse criticism had they appeared in the body of the paper in connection with medical description. We are glad to see that in the current issue of this journal an apology to the medical profession appears in place of the advertisement. It is ample, and is surrounded by a heavy black line suggestive of mourning. The terms of the apology, however, make it appear that the advertisers have

been led to believe that their notice was objected to on account of the manner in which it was illustrated. In all probability this would not have given rise to so much unfavourable comment, had the letterpress connected with them been more carefully drawn up.

A Fresh Source of Infection.

It is becoming difficult to know what any ordinary individual may do without running the risk of infection. Danger seems to lurk everywhere—indoor there are the many risks of dust-laden air, and outdoor, whether walking, cycling or driving, risks attend our every action. Now we learn from a German contemporary that for some forms of bacilli ordinary writing ink is little more than a cultivation fluid, and that the mouth and tongue troubles of early life, which are usually considered as brought about by dyspepsia, are in reality due to ink bacilli that the child gets from sucking its pen. Truly the inkpot has become as the flash of Cleophas. It was bad enough when it gave forth envy, malice, and scandal, but until now we never suspected it of adding a torture to childhood.

A Case of Curious Congenital Deformity.

THE lay public have always taken a lively and speculative interest in the study or, at any rate, the inspection of human congenital deformity or abnormality. Paragraphs in the lay press descriptive of such cases are eagerly scanned, and particular points noted for comment and reiteration in the tramcar, club, or home. The news of the definite conclusion of a treaty of peace between two belligerent nations can scarcely be more rapidly or industriously spread abroad than was the account of the surgical procedures which recently effected the separation of "Siamese" twins abroad. Few more interesting subjects can engage the mind of the scientific surgeon than that of congenital deformity. One of the most recent cases published is that of a lad fourteen years of age, who possessed three perfectly formed legs, two of which were used ordinarily in walking, but the three could be used together in standing. Beside perfectly developed male genitals, there was between the middle and third legs a well-developed penis with a non-patulous urethra, also two full-sized descended testicles, and a cleft scrotum, the cleft apparently leading to a bladder, which was quite independent of the normally situated bladder.

The William Smyth Memorial Fund.

THE fund for the family of the gallant Dr. William Smyth, who, as our readers will remember, contracted typhus fever while attending fever-stricken patients and transporting them in a boat from the island of Arranmore to the mainland, has been finally closed. The total amount collected is £7,629 1s. 7d., towards which the Dublin collection supplied £3,636 17s. 9d.; the Belfast collection, £1,705 10s. 8d.; the Londonderry collection, £1,507 13s. 2d.; and the London collection, £779—£7,629 1s. 7d. This sum has been lodged in the Bank of Ireland to the credit of the trustees to the

fund; and the terms of the trust deed assign the interest on one-half the whole sum to Mrs. Smyth for her life. The interest on the other half is assigned for the present to the maintenance of the children, while the trustees have the power to utilise a proportion of the capital sum for the further advancement of the children, as they may from time to time deem advisable. We rejoice to hear that so substantial a sum has been collected, and congratulate the treasurers of the Fund most heartily on their success. Dr. Smyth's gallant action will be long remembered both by the general public and by the medical profession, whose traditions of self-sacrifice and devotion to duty he so nobly maintained.

Second-Hand Clothes.

THE trade in second-hand clothes is a flourishing one as can readily be ascertained by a visit to the markets where they form the staple article of commerce, to say nothing of the thousand and one "wardrobe dealers" who eke out what is by no means invariably a precarious living by finding customers for articles of attire which, for some reason, have ceased to please their original proprietors. The odour of these derelict garments of itself is suggestive of infectious possibilities and the circumstances under which they have come into the market would doubtless, if we could only ascertain them, confirm the uneasy suspicion that in many instances such articles must be the means of disseminating infectious disease. These garments are often those discarded by persons who have gone to their long home as the result of acute disease, and in a certain but unascertainable proportion, no doubt, of infectious disease. Unfortunately, the premises of the second-hand clothes dealer are *ultra vires* so far as sanitary officials are concerned, and no means have yet been devised by which this danger can be removed or even minimised. Short of the impossible step of forbidding dealings in such articles, it is not easy to suggest a method of ensuring their freedom from infection. Beggars, we know, must not be choosers, but it is hard that to the indignity of wearing these borrowed plumes the unhappy customer should also be exposed to the risk of contracting disease, a risk the reality whereof has been amply demonstrated.

Small-pox in London.

THE outbreak of small-pox in the Metropolis continues at about the same figures that marked the slight diminution of the previous week. On Friday last the total number of cases under treatment in the Asylums Board hospitals was 1,446. The amount of decrease can be accurately estimated from the fact that the hospital admissions for the past fortnight numbered 605 as against 792 during the previous two weeks. It is necessary to impress upon the public the fact that the decline is due to seasonal influences, merely, and that it by no means entails any diminution of the necessity to be revaccinated. A very large

unvaccinated residuum among the inhabitants of London still leaves ample pabulum for the disease when, with change of season, it again comes to the fore, as, according to precedents, it is likely to do when summer gives place to the lower autumnal temperature. We insist upon this point because a tendency has already made itself manifest in sundry quarters to relax the pressure in favour of general re-vaccination. The total number of metropolitan and extra-metropolitan admissions were 7,145 since the beginning of the outbreak, and of that number 1,108 have died. The Essex County Council still continue their objection to the hospital ships moored on the Thames within their jurisdiction. Although it is unfortunately impossible to doubt that a good many small-pox cases have been contracted from the ships, yet it seems equally clear that the Metropolitan Asylums Board must find some place of refuge for small-pox cases. Isolation on a great river appears to afford the best and most reasonable means of obtaining the sort of accommodation needed. The body of the patient who escaped from one of the hospital ships in a delirious condition has been found in the Thames. The latest returns of small-pox have been: On Sunday 29 fresh cases.

Reunion of Obstetricians and Gynæcologists.

SPECIAL arrangements have been made for a meeting in London of obstetricians and gynæcologists of the Empire during Coronation Week. There will be a reception, followed by a dinner, at which Sir John Williams, Bart., will preside. All medical practitioners from the United Kingdom and British Colonies and Dependencies will be welcomed. Further details will be found in our advertising columns. Details of the reception will be published later.

The Registrar-General on Vaccination.

THE recently-issued report of the Registrar-General confirms in the most conclusive way the conclusions already forecast by the fragmentary statistics hitherto available in regard to the present epidemic of small-pox. The returns show that of 398 cases in which death occurred in unvaccinated persons, 56 were of infants under twelve months of age, 112 between the age of one and five years, 58 between five and ten, and 37 between ten and fifteen. Of persons not vaccinated since infancy 158 died between forty and sixty years of age, and no less than 260 between twenty and forty. Not a single death occurred among those vaccinated in infancy under the age of ten, and there were only 5 between ten and fifteen. If these statistics are not conclusive it is difficult to suggest by what process of reasoning waverers are to be convinced.

Birmingham Consultants and the Working Classes.

DR. ROBERT SAUNDBY forwards us a long correspondence, for which we are unable to find space, but which shows how baseless are the statements made

in the Press to the effect that the Birmingham consultants have shown themselves indifferent to the desire of working men to be allowed to pay half-a-guinea for a "consulting advice" rather than resort to hospitals. As a matter of fact, as this correspondence shows, the consultants have shown every willingness to accede to this reasonable request, although, of course, precautions have had to be taken to avoid the abuse of a concession which is restricted to the *bona-fide* wage-earning working man. A list of fifty-three consultants and specialists willing to further grant this concession has been drawn up and placed at the disposal of friendly societies and similar bodies.

PERSONAL.

DR. W. J. COLLINS, L.C.C., has been elected President of the newly-constituted Medico-Legal Society.

DR. LAIRD, Assistant Medical Officer of Health for Lanark, has been appointed Medical Officer of Health for Crewe.

MR. J. TELFER THOMAS, L.R.C.P., M.R.C.S., of Penven, Camborne, has been sworn in as a Justice of the Peace for the County of Cornwall.

DR. G. B. FERGUSON, Surgeon to the Cheltenham General Hospital, has been elected a Fellow of the Royal College of Surgeons of England.

DR. JAMES CRAUFORD DUNLOP has been appointed Inspector of Certified Inebriate Reformatories in Scotland and Inspector of Licensed Retreats.

THE LORD MAYOR OF LONDON, Sir Joseph Dimsdale, M.P., will preside at the sixty-sixth annual dinner of St. Mark's Hospital, City Road, which is to take place on the 24th inst.

MR. C. T. RITCHIE, M.P., will be the Unionist candidate for the Lord Rectorship of the University of Aberdeen, in opposition to Mr. Asquith, who is the Liberal candidate.

DR. GEO. P. O'CONNOR, late of Chatteris, Cambridge, who has held the office of District Surgeon in Natal South Africa, has been appointed Justice of the Peace for the Alfeld Division, during the pleasure of His Excellency the Governor.

DR. DUNCAN McDONALD, late Medical Officer of Mull, has been presented with a purse containing a hundred guineas on the occasion of his leaving the district for Oban. As Dr. McDonald had only been in the parish for a little over six years he had evidently lost no time in ingratiating himself with the inhabitants.

THE vacancies which have existed for some time among the Surgeons-General have been filled by the appointment of Colonels Burnett, Townsend, McNamara and Sir Thomas Gallwey. The claims of a large number of senior Colonels for promotion have been passed over because they are of an age which would preclude their putting in the regulation period of three years as Surgeons-General.

PRESENTATIONS AT THE LEVEE.

The following members of the profession had the honour of presentation to the King on Monday last, the 21st inst.:—Captain John Allison, M.D., Captain J. W. Bennett, R.A.M.C., Dr. John Broadbent, Lieut. L. Cotterill, R.A.M.C., Surgeon-Lieut.-Col. D. Cowie, M.B., Lieut. B. A. Craig, R.A.M.C., Lieut. H. S. Collier, R.A.M.C., Lieut. Thomas F. Devane, R.A.M.C.; Deputy-Inspector-General A. G. Delmage, M.D., on his appointment as Honorary Surgeon to the King; Dr. G. B. Ferguson, President of the British Medical Association; Lieut. A. J. M. Cuddon-Fletcher, R.A.M.C., Staff Surgeon Wm. E. Home, M.D., Lieut. W. J. S. Harvey, R.A.M.C., Lieut.-Col. H. E. B. James, R.A.M.C., Surgeon-Major C. E. Kilkelly, C.M.G., Lieut. P. S. Lelean, R.A.M.C., Lieut.-Col. C. A. MacMunn, R.A.M.C., Surg.-Lieut. J. M. B. McKie, Surg.-Lieut. L. J. H. Oldmeadow, M.D., Dr. Henry Owen, Major S. E. Prall, Indian Medical Staff, Staff Surgeon E. B. Pickthorn, R.N., Surgeon-Lieut. B. Roche, Surgeon-Lieut. Charters J. Symonds, M.D., Lieut. B. H. Smith, R.A.M.C., Lieut. H. Fulham-Turner, R.A.M.C. (Vols.), Lieut. T. Barton Unwin, R.A.M.C., and Dr. Whitelegge.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

NATALITY IN GREAT BRITAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—“Neoplasm’s” letter seems permeated with the pessimism of the day, and is so far interesting. Few, however, will agree with him that “a decreasing birth-rate is merely an indication of (national) senility.” The nations which seem started on a course leading surely to destruction would be better described as only just reaching the adult intellectual age. For the first time in history science has advanced to a point which gives mankind the conscious control of their physical and moral future. Ancient dead peoples—the Egyptians, the Greeks, the Romans—had learning, philosophy, and poetry, but virtually no science; they as nations committed what “Neoplasm” calls “automatic suicide,” but they did it blindly. Civilised nations of the present age if they destroy themselves will do it with their eyes open, or at least with the full comprehension of their act by all those who have mental eyes to see. To avert physical degeneration and decay the eradication of preventable disease would seem the first step called for. Not only is the birth-rate low in France, but the preventable destruction of infantile life is enormous. If this were put an end to the population would be no longer shrinking, whilst the physical standard of the nation would probably be raised all round. For it must be remembered that high juvenile mortality means damaged constitutions in a large proportion of the survivors; they escape with their lives, but sorely wounded. If the nations would put their sanitary institutions on a level with science most of the diseases which tend to deterioration of the species might be done away with. Tuberculosis, in all its phases, syphilis, rickets, typhoid fever, and most, if not all other zymotic diseases might be made within comparatively a few years in civilised lands as rare as the plague. A properly arranged system of emigration would carry the surplus populations to colonies crying out for them, and with territories wide enough to support countless myriads. Western civilisation—peace, law, and human freedom—would thus in time dominate the habitable globe. At least all that would be further needed to ensure such an approach towards the Millennium would be an advance with equal steps in moral improvement. Every nation will decay when its members as a body lose the capacity for self-sacrifice, when their highest ideal becomes mere egoism—a life free from toil, strife, and pain, and of renunciation for the good of the family, the community, the State, and posterity. In teaching and proving these truths science here comes to the aid of

religion. The nations which reject such teachings are surely doomed.

I am, Sir, yours truly,
April 16th, 1902.

LATENT PNEUMONIA AND BAD WHISKY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In looking over a very interesting article in the *Edinburgh Medical Journal* for April, on fatal cases of latent pneumonia, appreciation of the statistical tables of the cases lead me to offer a few suggestions. Some two years since, I went to Manchester on the outbreak of the beer-poisoning cases, and visited the infirmary there to see the patients, and was shown that the symptoms and fatalities were due to arsenic contained in that intoxicant. It seems to me, then, that these cases of fatal latent pneumonia might probably come under much the same category here in Edinburgh as in Manchester, and might be the result of poisonous whisky imbibed by the victims of intoxication, and not the result of alcoholism simply.

About two months ago a full detailed article appeared in the *Scotsman* on the “Analysis of Modern New Whisky,” which showed that it consisted not of pure grain spirit, but of a mixture of aldehydes, fusel oil, ferfusel, naphtha, beryl, &c., and some had been distilled with glucose. This concoction could not be termed Scotch whisky, but more appropriately German whisky, and may therefore prove deleterious to the native stomach and constitution, and may have other poisonous ingredients in it yet undiscovered. I might therefore suggest that in future well authenticated fatal cases that samples of the whisky that had been used as a regular intoxicant by the party might be got and analysed for deleterious ingredients suspected. It is of common repute that the vile new whisky used by the slumming classes now tends to incite to violence and rioting and it may therefore be well imagined that this effect might be due to irritant poisons contained in its course of manufacture.

One peculiarity of this latent pneumonia about Edinburgh seems to consist in its ingravescent character, the gradual invasion of consolidation of the lungs, without reflex cough and dyspnoea or sanguineous expectoration, till the circulation comes to a stop, and a fatal issue takes place by collapse.

Yours very truly,

W. G. BLACK, F.R.C.S.E., S.M.
2, George Square, Edinburgh.

THE MANIPULATION OF MILK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a London daily newspaper of the 10th inst. is published some remarks about milk with the heading “Pure Milk is Coming,” but on reading the effusion to the end I find it really explains that more drugged milk is coming; milk drugged by the infusion of manufactured oxygen into its nature. Now if such milk keeps for six months, as it is stated to do, the editor of an English paper is encouraging the probable importation of more stale milk produced and (incorrectly) preserved in France and other Continental countries, under no sort whatever of early British control as to cleanliness, purity, or safety of production, by the process and treatment of what they assume to be a French invention! In their writing up of this imaginatively wonderful process they seem to forget, or to be unaware (1) that oxygen exists in all pure air to the extent of 23 per cent.; (2) that there is excellent pure air at English milk-supplying farms wherewith to purify and aerate the warm milk of the cow quickly after being milked; and (3) plenty of portable, handy, and automatic appliances for the purpose in existence for use at farms that can not only aerate but cool the milk, with the aid of ice, or intensely cold water, down to a non-fermenting temperature; (4) that such milk can be conveyed so cooled to the consumers’ doors absolutely free of ferment or germs, in a natural sterile condition—fresh, pure and sweet; while (5) it may be that this new French invention will be found to infringe an American patent, now in use for

some time, for preserving milk in syphons and bottles by the process of natural aeration in a pure atmosphere with Nature's oxygen versus the manufactured article! It seems to me that they have acted very imprudently and unguardedly in announcing, advertising and encouraging this French invention for artificially preserving milk, and, with due respect to their further mistaken teaching, in direct opposition to the conclusions of the Expert Committee of your Local Government Board for investigating these matters of drugging milk, who finally, and correctly, decide and publish in the Blue Book of your country, that "it is idle to pronounce it impossible to supply London with milk not artificially preserved." Yet, in the face of this, that journal has the audacity to recommend a French system of drugging milk by the "artificial" process of infusing manufactured gas into its nature. It is truly most astonishing how peculiar and thoughtlessly inconsiderate English people can possibly prove themselves to be. Englishmen should remember that the French systems of Pasteur they hang on to so unwisely are all plans for the late curing of evil in milk, that the word "prevention" does not apply, but that all of them alter and impair its nature. This latest fad, however, of drugging milk with gas should open the eyes of the British farmers and public to the folly they are being led into, like a ringed-nosed bull led by a Frenchman's chain! Prevention of evil in milk by early purification and effective refrigeration—as an improvement upon, and development of, current methods of mere cooling—is all that is wanted. You in England are already on the right tack and principle, all that is required is its betterment by the aid of ice, proper appliances, conveyances, and cold storage. Chuck the Frenchmen and all belonging to them, and support M. A. Robinson (the most unselfish, best, and truest friend the English dairy industry has ever possessed) and me in our endeavours to substitute a supply of sound versus unwholesome and impaired milk throughout the British Empire. Prevention is better than cure.

I am, Sir, yours truly,

L. J. SEERIN, A.E., State Agricultural Expert.
Mont-sur-Marchienne, Charleroi (Belgium),
April 19th, 1902.

THE HOSPITAL OF ST. FRANCIS.—AN ANTI-VACCINATIONIST HOSPITAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The attention of the Council having been drawn to an article in your issue of April 9th, in which you criticise the remarks made from the chair at our Annual Court held on March 25th I am instructed to say that we have communicated with the gentleman who occupied the chair, and that he has in reply written to us "I am solely and entirely responsible for the views I expressed."

In these circumstances it is manifestly unfair to attribute to the Council or staff the views and opinions for which the chairman himself states that he alone is responsible. I enclose a copy of the rules under which the hospital is conducted, in which you will observe that the particular views you complain of find no place.

I am sir, yours truly,

HARRY COCKING, Secretary.
Hospital of St. Francis, New Kent Road, S.E.,
April 21st, 1902.

[Either the views expressed by the chairman are endorsed by his colleagues on the Board or they are not, and in the latter case we would suggest that it is incumbent upon them and on the medical staff to disassociate themselves from views so absurd and indefensible.—Ed.]

An Extraordinary Death.

A CURIOUS incident is reported to have taken place a few days since at the South Devon and East Cornwall Hospital. A man who had come for an injury to the head while under the influence of acute alcoholism found his way into a ward and swallowed the contents of the medicine stock bottles with promptly fatal results. A verdict of death by misadventure was returned at the inquest.

Obituary.

THOMAS MORE MADDEN, M.D., M.R.C.P.I.,
F.R.C.S. Edin., J.P.

It is with sincere regret that we announce the death of Dr. Thomas More Madden, which took place on Monday, the 14th inst., at his country residence, Tynede, co. Wicklow. By his death one of the few remaining links with the past is severed. It is more than half a century since his apprenticeship to that great surgeon, James Cusack commenced. He knew all the mer. who gave the Dublin school a European reputation. He was born in the island of Cuba, in the thirties, at which time his father, Dr. E. B. Madden, was British Commissioner at the International Congress for the Abolition of the Slave Trade, and he ever referred with pride to the part his father took in carrying out Stanley's Emancipation Act. Born at such a time, whilst as yet the world echoed with the voices of Johnson, Freeman, Wilberforce, and Buxton, and learning, at his father's knee of Grenville Sharp and others, Madden commenced life with the high ideas of an heroic and philanthropic age, which were strengthened by his being named after the author of "Utopia." As a boy he learned Spanish, and throughout life it remained dear to him. The last time the writer heard his voice, it was the *muy gracias* of the sonorous Spanish for some slight favour shown him. His early studies ran down his health, and in 1859, after obtaining his first qualifications, he commenced travelling for health sake. He, however, returned in time to stand amongst the little crowd that saw and admired Marion Sims' first operation, when that great Southerner demonstrated his operation for vesico-vaginal fistula. He spent a session at the Montpellier School of Medicine, and sought out the site of lecture theatre of Albinus and the room of the "*Anglin lumen*," Sydenham. He rambled throughout Spain and studied the Moorish architecture, and visited the ruins of the old medical schools, in some of which medical instruction was still carried on in the sixteenth century manner. From Spain he journeyed through Northern Africa, from Morocco to Egypt, and hence he went to Australia. These journeyings were not without result, and on his return he published "Change of Climate," "The Spas of Germany, France and Italy," and "Health Resorts of Europe."

He finally decided on commencing practice in Dublin, became assistant to the Master of the Rotunda Hospital, gynaecologist to the Mater Misericordia Hospital, consulting physician to St. Joseph's Hospital for Children, and consultant obstetrician to the National Lying-in Hospital, Halles Street. On the outbreak of the Franco-Prussian War, Dr. Madden organised an Irish ambulance company, which he accompanied to Paris and offered his and their services to the French. For his services on this occasion the Republic conferred on him the decoration of the Bronze Cross. At the termination of the war he returned, and was soon afterwards elected an examiner in obstetrics in the Q.U.I. For his writings on gynaecology he was accorded a gold medal by the Associazione die Benemeriti Italiani. He was honorary President of the first International Congress of Obstetrics and Gynaecology at Brussels in 1872.

From the commencement of his professional career to its end Dr. Madden was an industrious and facile writer. It is almost forty years since he became a contributor to the MEDICAL PRESS AND CIRCULAR, since then his articles appear in almost every volume, and are to be counted by the hundred. As might be expected, in later years his papers were principally devoted to questions connected with his own speciality. Occasionally, however, he dealt with matter outside it, as in his papers on the "Medical Lore of the Early Irish," and his address on "Irish Medical Schools," delivered some years since at the Mater Misericordia Hospital, on which occasion he was complimented by Mr. Justice William O'Brien as "one in whom eloquence was hereditary, and like a river the current flowed more full and strong as it passed onwards."

He was a constant attendant at the gynaecological meetings of the R.A. of M. in Ireland, and the Transac-

tions from their first number bear evidence of his industry as a writer, his acumen as a practitioner, and his grasp of the scientific knowledge of his profession. As a man, Dr. Madden was courteous to all, tenacious of his rights, withal punctilious in recognising the rights of others, of decided opinions, and a passionate lover of his country. His likes and dislikes were strong, and once he gave his friendship he was ever afterwards a trustworthy friend. There are many who will grieve that they will see his face no more.

ALEXANDER MACGREGOR, M.D. Aberd., M.R.C.P.
London.

THE sudden and altogether unexpected death of Dr. MacGregor has come to his friends and colleagues as a great shock. Dr. MacGregor was a man of active habits, vigorous intellect, charming personality, an able physician, and a true friend. In Aberdeen he filled several important posts with distinction, and was at one time candidate for the Chair of Medicine. As one of the physicians to the Mount Vernon Hospital for Consumption he was enthusiastic in the study and treatment of phthisis, and greatly respected by his patients. To pass from an active and useful career at the early age of 48 leaves life's work unsatisfied. Much sympathy will be extended to the widow and her infant daughter.

INSPECTOR GENERAL ALEX. WATSON, R.N.,
M.D.

THIS gentleman, who died at his residence, at West Derby, Liverpool, last week, was a graduate of Edinburgh University. Having obtained his M.D. degree in 1847, he entered the Naval service the year following, and was engaged as Assistant Surgeon of the *Highflyer* in the Black Sea during the Russian War, and was present at the principal operations, receiving for his services the Crimean and Turkish Medals, with Sebastopol clasp. He was Surgeon of the *Cormorant* on the China Station, and was again mentioned in despatches for services rendered at the capture of the Peiho Forts in May, 1858. In the following year he was wounded, and his vessel sunk in action at the second attack on the same forts. He was subsequently in medical charge of the seriously wounded till their arrival in England, for which he had the China medal with clasp for Taku. As Staff Surgeon of the *Challenger* on the Australian station, he was present at the attempted assassination of the late Duke of Edinburgh at Sydney in 1868, and extracted the bullet from, and was in constant attendance upon, his Royal Highness till his recovery. He was a third time mentioned in despatches, and was specially promoted to be Fleet Surgeon in July, 1868. He subsequently served as Fleet Surgeon in the *Galatea* and on the staff of the Duke of Edinburgh on his visit to India, China, and Japan, and as Fleet Surgeon in the *Serapis* with the King, when as Prince of Wales he visited India in 1876-7. In 1881 he retired on promotion, with the honorary title of Inspector General of Hospitals and Fleets.

Literature.

GRAY'S ANATOMY. (a).

EVERYONE will have a hearty welcome for the fifteenth edition of the friend of their youth—the celebrated Gray's "Anatomy." It has served as the teacher of generations of students, and will in all probability, serve as the teacher of generations more. In the present edition the entire work has undergone a careful revision. The section on Embryology particularly has been improved by the introduction of some sixty additional illustrations after his and others. We confess that we

should like to see a still further revision of the illustrations in a few instances. Figure 563, representing a vertical median section of the female pelvis, does not ornament the pages of a standard work on anatomy. It is incorrect in its anatomical representations, and is besides by no means on a par with the other illustrations when viewed from the standpoint of the artist. Such illustrations however are entirely exceptional, and the editors and their assistants must be congratulated on the manner in which they have discharged what must have been a most difficult and laborious task. In the sixteenth edition we shall look forward to seeing a chapter on the anatomy of the human body as determined by skiagraphy, an innovation which must sooner or later find its way into works on anatomy.

Medical News.

A Medical Witness's Fees Disputed.

DR. GEORGE R. LORIMER, of Burton, was the plaintiff in a recent County Court action, in which he sought to recover the sum of £25 12s., being his fees as witness in a Chancery action in reference to the will of a deceased patient. The sum comprised five guineas for preparing the case and five guineas a day for attendance, exclusive of travelling and other expenses. The defence urged that Dr. Lorimer was merely a witness as to fact and not an expert and offered £8 8s. in settlement. The Judge held that the plaintiff was called as an expert witness, adding that his time was certainly worth more than the fee charged, and he gave judgment accordingly.

A Meeting of Philosophers at Carlsbad.

THE seventy-fourth annual congress of the Association of Natural Philosophers and Physicians will take place at Carlsbad in the last week of September. It is officially announced that the meeting is for purely scientific purposes, and there will consequently be no "social side." It speaks volumes for the popularity of natural science that some 8,000 persons from all parts of the world have already intimated their intention of being present.

Sleeping Sickness in Central Africa.

A MEDICAL Commission is shortly to proceed to Uganda to investigate the epidemic of sleeping sickness, which has broken out in the Protectorate, and on some of the islands and country places in Uganda it has carried off hundreds of victims. The disease is characterised by a gradually increasing drowsiness, with prostration, and no authentic case of recovery from the disease has yet been recorded.

Mortality in Foreign Cities.

ACCORDING to official returns supplied to the Registrar-General, the death-rate of the various populations per thousand for the latest week to hand was: In Calcutta 42, Bombay 112, Madras 44, Paris 22, Brussels 16, Amsterdam 18, Copenhagen 18, Stockholm 19, Christiania 12, St. Petersburg 24, Moscow 24, Hamburg 15, Munich 20, Vienna 23, Prague 24, Budapesth 20, Trieste 30, Rome 23, Venice 27, Cairo 26, Alexandria 32, New York 19, Philadelphia 19.

Meath Hospital.

AT the annual meeting of the Governors of the Meath Hospital held on April 14th, Mr. Arthur Andrews, J.P., in the chair, the Secretary presented the 148th annual report, which showed that at the commencement of the financial year there was a debit balance of £1,171 10s. 9d. The total expenditure was £5,991 19s. 4d., and the ordinary income £5,542 13s. 10d., thus showing a deficiency on the year of £449 5s. 6d., and leaving at the close a balance against the hospital of £1,620 16s. 3d. The Committee much regret this unsatisfactory condition, which has been occasioned by their desire and efforts to meet to the utmost the great demand made by the sick poor who daily seek admission. There were in the wards on April 1st, 1901, 113 patients, 1,312 were admitted during the year, making 1,425; of

(a) "Anatomy, Descriptive and Surgical." By Henry Gray, F.R.S., F.R.C.S., Lecturer on Anatomy at St. George's Hospital Medical School. Fifteenth edition, edited by Pickering Pick, F.R.C.S., Consulting Surgeon to St. George's Hospital, &c., and Robert Howden, M.A., M.B., Professor of Anatomy in the University of Durham, &c. Pp. xliii. (148) and 1096. London: Longmans, Green and Co., 1901.

these 1,248 were discharged, cured or relieved, 66 died, and 111 remained on March 31st, 1902. The mortality was 5.02 per cent. on the total treated to a termination. There were also 5,177 accident cases treated as out-patients, and the dispensary cases numbered 18,009. There was, therefore, a total of 19,611 persons who received medical or surgical treatment during the year. The report concluded with an earnest appeal for funds. The medical report was presented by Dr. Lennon and the surgical by Mr. R. Lane Joynt, F.R.C.S., both of which were of a very satisfactory character.

In a return issued by the Hospital Sunday Fund, the total expenditure per bed per year was given in the case of six hospitals. In five of these the figures were £83 6s., £80 5s., £83 8s., £83 3s., and £79 10s. In the sixth hospital, the Meath, the return was only £53 16s. It might be said that their economy consisted in starving their patients, but from the figures published by the fund they would see that in the hospital which cost £83 per bed per year provisions cost £13 15s. 11d., whereas in the Meath Hospital, with an expenditure of £53 16s., the provisions cost £16 0s. 6d., which supported the contention of the managers that its economies were effected in other directions. The hospital was stated to be in a thoroughly efficient condition, and the report was, on the motion of Dr. Craig, adopted unanimously, and after the transaction of the remaining business the meeting terminated.

The New Ulster Medical Institute.

ON April 12th last the foundation-stone of an institute in connection with the Ulster Medical Society was laid by Professor Redfern, M.D., F.R.C.S. The Society, though in existence for a considerable number of years, has had no regular meeting-place of its own, and the need of such a building, where the members could assemble, either for professional or educational purposes, was keenly felt. Professor Whittle, M.D., J.P., who is well known to his professional brethren, came to the rescue, and at the last annual dinner of the Ulster Medical Society, of which he is the president, he signified his intention of erecting and equipping an institute. A site for the building has been leased from the governors of the Royal Belfast Academical Institution, and, when erected, the new institute will be fitted up in the most complete manner with all necessary requisites. The front of the building facing College Square North is designed in Perpendicular Gothic work, and consists of Scarbo rock faced ashlar and Dumfries red sandstone dressings. It presents a frontage of 45 feet to the street, by about 46 feet high to the top of the parapet, with a gable in the centre. It is expected that the building, which will cost about £6,500, will be ready for opening before the end of the present year.

University of London.

In the list of medical schools of the University and of hospitals and institutions recognised by the Senate of London University for the complete course of medical education, including clinical medicine and surgery, appears the University of Birmingham, with the General Hospital, or Queen's Hospital, as well as the University College of South Wales, with the Cardiff Infirmary (for first three years only), and the University College, Bristol, with the Royal Infirmary or General Hospital. These are in List I., while List II.—which is that of hospitals recognised for the attendance on medical and surgical practice required for the degrees of M.D. and M.S.—includes among the general hospitals unconnected with medical schools the Wolverhampton and Staffordshire General Hospital, the North Staffordshire Infirmary, Stoke-upon-Trent, and the Cardiff Infirmary.

Royal College of Surgeons in Ireland.

THE annual dinner will be held at the College on Saturday, May 10, at 7.45 p.m. His Excellency the Lord-Lieutenant, K.G., has graciously accepted the invitation of the President and Council to be present. The President and Council having voted the Honorary Fellowship of the College to Surgeon-Captain Thomas Joseph Crean, V.C., for his distinguished services in

South Africa, the formal presentation to him will take place at 7.30. As the accommodation will of necessity be limited Fellows desirous of being present at the dinner should send their names and those of any guest they may wish invited to Mr. G. F. Blake, Registrar, Royal College of Surgeons, before May 1st, 1902.

A Vaccination Scare.

A RUMOUR having gained currency that the children attending the elementary schools at Newhall, Burton, were to be vaccinated one morning of last week, very few scholars put in an appearance, and the schools were besieged by angry or tearful parents. The school had to be closed for want of pupils, and other schools, some miles distant, had likewise to be closed on account of the threatening attitude of the crowds. This occurrence shows to what a degree the pernicious influence of the mendacious statements, distributed broadcast by the anti-vaccinists have inflamed the minds of the ignorant and unreasoning.

Strange Misadventure.

A CABMAN was admitted to the Hôpital Dubois one day last week complaining of intense gastralgia. No diagnosis could be made, and it was decided to perform an exploratory operation, but before this could be done he had a violent fit of vomiting, which resulted in the ejection of a piece of rubber tubing. He died on the following day, and it is asserted by his friends that the tubing was left in the stomach by his medical man after a lavage.

War Medals.

WE are informed by the War Office that South African medals are now ready to be issued to those members of the Medical, Staff, Rhodesian Field Force, and Cape Stretcher Bearers attached thereto who are entitled to them. Applications for these medals by men of this corps who are resident in this country must be accompanied by the applicant's discharge certificate or other papers of identity, and addressed to the Director-General, Army Medical Service, 18, Victoria Street, London, S.W.

Death under Chloroform.

A MAN, aged 38, who was about to be operated upon for varicose veins at the Royal Albert Hospital, Devonport, became violent and died after only five minutes' inhalation, the explanation being "spasm of the respiratory muscles, due to chloroform," a new symptom in chloroform narcosis! The stereotyped verdict was returned, and no reference is made in the report to the quantity used or the mode of administration.

Royal College of Surgeons, Ireland.—Election of Examiners.

A MEETING of Fellows will be held on Tuesday, May 6th, in order to elect the following Examiners:—Two Examiners in Anatomy, to examine in Surgery when directed. Two Examiners in Surgery, to examine in Anatomy when directed. Two Examiners in Physiology and Histology. Two Examiners in Ophthalmology. One Examiner in Pathology and Bacteriology. One Examiner in Pathology. One Examiner in Midwifery and Gynaecology. One Examiner in Biology. One Examiner in Sanitary Law and Vital Statistics. One Examiner in Engineering and Architecture. Two Examiners in Chemistry and Physics. Two Examiners in Dental Surgery and Pathology. Two Examiners in Mechanical Dentistry. One Examiner (not being a Fellow or Licentiate of the College) in Languages. One Examiner (not being a Fellow or Licentiate of the College) in Mathematics, Physics, Dictation, and English Essay. Candidates must lodge their applications with the Registrar, at the College, on or before Tuesday, April 29th, at 10 a.m.

The following is the prize list for the winter session 1901-1902:—

Stoney Memorial Gold Medal in Anatomy.—J. J. Connolly. Descriptive Anatomy.—Junior: W. St. L. Moorhead, first prize (£2) and medal; L. Lucas second prize (£1) and certificate; senior: E. Bury, first prize (£2) and medal; I. Allaun, second prize (£1) and certifi

cate. Practical Anatomy.—First year: J. B. Kelly, first prize (£2) and medal; J. Prendiville, second prize (£1) and certificate; second year: E. Bury, first prize (£2) and medal; R. A. Brown, second prize (£1) and certificate; third year: J. J. Connolly, A. N. Crawford, and J. Parker (equal first prize (£1) and medal. Practice of Medicine.—M. Lochrin, first prize (£2) and medal; J. S. Sheill, second prize (£1) and certificate. Surgery.—J. S. Sheill, first prize (£2) and medal; W. R. Ormsby, second prize (£1) and certificate. Midwifery.—J. J. Connolly, first prize (£2) and medal; F. O'D. Fawcett, second prize (£1) and certificate. Physiology.—R. A. Brown, first prize (£2) and medal; E. Smith, second prize (£1) and certificate. Chemistry.—L. Lucas, first prize (£2) and medal; E. F. Ward, second prize (£1) and certificate. Pathology.—R. W. Burkitt, first prize (£2) and medal; W. R. Ormsby, second prize (£1) and certificate. Physics.—L. Lucas, first prize (£2) and medal; E. W. Greene, second prize (£1) and certificate.

Pass Lists.

University of Birmingham.

The following candidates have passed the first and second examinations for the degree of Bachelor of Medicine and Bachelor of Surgery during April:—

First Examination.—Class I.: Herbert Charles Horace Bracey.

Class II.: John Staines Austin, Henry Neville Crowe, Lionel Chattock Hayes, Richard Stuart Wathen Hunt, G. Frederick Jotham, Walter Rowland Southall Roberts, Spencer Graham Walker, Edmund Stanley Whitcombe.

Second Examination.—Class II.: Fred Thomas Holloway Davies, Fred Newton Walsh, Herbert Henry Warren. Royal College of Physicians, Edinburgh, Royal College of Surgeons, Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

TRIPLE QUALIFICATION.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on April 8th, with the following results:—

First Examination, four years' course.—The following two candidates passed the examination: James Henry Allan and Isa Charan.

First Examination, five years' course.—Of twenty-four candidates entered, the following eleven passed the examination: Ernest Averell, Hector Graham Gordon Mackenzie, Herbert Bower, Henry Albert Pascoe, William Wallace Dunlop, James Sullivan, Robert James Martin, Elizabeth Mary Cardozo, Daniel Kennedy, Patrick Raoul Eskell, and James Noonan. Three passed in Physics and three in Chemistry.

Second Examination, four years' course.—Of seven candidates entered the following five passed the examination: Isa Charan, Robert Gibson, Lewis Pemberton Anderson, Alexander Wood, and Ernest Arthur John Eraser; and one passed in Anatomy and Physiology.

Second Examination, five years' course.—Of twenty-seven candidates entered the following sixteen passed the examination: John James Gillis, Gideon Hendrik van Egl, Alexander Douglas Fox, James Watson, Ernest Saunt, Martin Arnold Gibbs, James Grieve Cormack (with distinction), James Wilson, Maurice Michael Fitzgerald, Elizabeth Mary Cardozo, Robert Murray Fraser, James Augustus Robertson, George Waller Meade, Ernest Howard Edward Coghlan, Edward Herrick Knowles, and Emile Reboul; and one passed in Anatomy.

Third Examination, five years' course.—Of thirty-five candidates entered the following twenty-six passed the examination: Fritz George Heyer, Donald Cameron, William Ernest O'Hara, Archibald Monteath Laurie, Leonard Bushby Hopper, Michael King, William John Morton, John Archibald Turnbull, William Black Andry, Joseph van Someren Taylor, William James Arves, Thomas McMaster Glen, Terence Owens, Patrick Law, Mutyala Sriramulu Naidu, James Cullen, Leo Ferdinand Bianchi, Andrew Malachy Walsh, Minnie

Green, George Alexander Paulin, William Charles Maasy Burnside, Thomas Russell, Behram Burjorjee Bharucha, Everard Clave, Eileen Fitzgerald, and Kaikursroo Jehangir Bhangara.

Final Examination.—Of sixty-eight candidates entered, the following thirty-eight passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. & S.G.:—Alice Esther Gilford, Wilfred Edwyne Knight, Frank Edward McGee, Hastings Footman Everett, Henry Ayrton Chaplin, James Linton Johnston, John William Cross, Elisha Preston Mead, Alan Leslie Fielding, Philip Henry Mules, Robert Walter Joseph Pearson, Martin Francis Cusack, Arthur Thomas Hoskins Linton, Farris Nusser Jaboor, Howard Horace Homer Hurdman, David Patrick Johnstone, Alfred Lambré White, Leonard Bushby Hopper, John Quin Donald, Thomas Albert Mendes, Robert Methuselah Stimpson, Reginald Herbert Brierley, Wilfred Albert Wilson, Thomas Roberts Griffiths, Daniel Randolph Gonsalves, Roger Llewellyn Williams, Sylvester Lawson Clindinin, Valiant Galfred Ffrost, Evan Bidie, Edith Boomgardt, Lionel Walpole Thomson, Thomas Longmore Ashforth, Thomas Glasbrook Davies, Debendranath Banerji, Thomas Jones Evans, Timothy Francis Heas, Donald Burrows, and John Anthony Freeman Hatch; and three passed in the division of Medicine and Therapeutics, two in Surgery and Surgical Anatomy, seven in Midwifery, and eleven in Medical Jurisprudence.

Conjoint Examinations in Ireland.

The following candidates have passed the first professional examination:—

A. Honours in order of merit.—I. I. Hogan, L. Lucas, T. P. Byrne, M. I. Coyne.

B. Passed in all subjects; alphabetically.—A. Hipwell, P. F. J. Leyland, R. Martin, E. Punch, P. J. Rooney.

C. Completed the examination.—B. N. Blood, C. Gordon, E. J. Higgins, R. V. Murphy, N. E. Sampey.

Preliminary Examination.—B. Bassett, W. J. Berne, P. Blake, F. G. Blood-Smyth, T. A. Buchanan, P. J. Cleary, J. D'Alton, T. Fitzgerald, B. Foley, H. D. Gilmore, W. J. Kennealy, W. Owens, C. W. C. Robinson, G. F. Shepherd, D. McC. Smith, J. F. Walsh, A. E. Weinstock.

Society of Apothecaries of London, April, 1902.

The following candidates passed in:—

Surgery.—W. Ball, B. M. Dunstan, J. W. Elliott, A. F. Heald, A. Holroyde, E. A. Houchin, W. St. A. F. Hubbard, G. R. Lucas, S. A. Rowley, T. Scatchard, P. Southan, J. A. W. Webster.

Medicine.—A. H. Bell, G. F. G. De Laubenque, A. Holroyde, E. A. Houchin, T. G. Miles, O. Millauro, G. Roper, C. J. Taylor, H. C. S. Woodward.

Forensic Medicine.—G. F. G. De Laubenque, A. Holroyde, T. Scatchard, C. S. Scott, C. J. Taylor, W. H. Tomlinson.

Midwifery.—G. R. Hannon, E. A. Houchin, W. St. A. F. Hubbard, A. H. Hughes, P. C. W. Laws, C. H. Osmond, A. L. Walters.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—A. H. Bell, A. Holroyde, W. St. A. F. Hubbard, G. R. Lucas, and P. Southan.

Pharmaceutical Society of Ireland.

The following have passed the Pharmaceutical Licence Examinations:—A. N. Yoxall, H. I. Gorman, B. Connolly, H. N. Forsythe, H. C. Thackeray, H. J. Owgan, H. Todd, H. I. Grubb, P. L. Doyle. Fourteen candidates were rejected.

Registered Druggist Examinations.—A. M. Gamble, T. Hanna, W. H. Howe, D. O. Perry, R. Verner passed. Four candidates were rejected.

Pharmaceutical Assistant Examination.—G. H. Batt, H. T. Grindley, J. Hunter passed. One candidate was rejected.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

A. B.—We regret the information came too late to be utilised. A note has been made, however, for future reference.

LINCOLN.—The book was not sent us for review or we should have spoken very plainly as to its nature. Our attention was drawn to it by a patient, hence the editorial reference in our last.

MR. CROLY ON THE LIGATION OF THE EXTERNAL ILIAC ARTERY.

We regret that owing to delay in the post the corrected proof of Mr. Croly's interesting paper on "The Ligation of the External Iliac Artery for Aneurysm, &c.," did not reach us until subsequent to the publication of the issue in which it appeared, and that consequently a couple of obvious errors in it escaped correction. In connection with this, we would impress on all contributors the necessity for returning corrected proofs sufficiently early to enable them to reach our office on or before the Monday prior to the date of issue. Otherwise it is impossible to ensure absolute accuracy.

Meetings of the Societies, &c.

LONDON.

THURSDAY, APRIL 24TH.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover Square, W.).—5 p.m.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Mr. R. Johnson: Some Points in the Treatment of Tuberculous Disease of the Knee. Dr. L. Guthrie: Congenital Hereditary Hematuria. Clinical Cases.

FRIDAY, APRIL 25TH.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 p.m. to 9 p.m.

EPIDEMIOLOGICAL SOCIETY (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Dr. Thresh: Small-pox Hospitals and the Spread of Infection.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—Demonstrations will be given at 4 p.m. as follows:—Monday, skin; Tuesday, medical; Wednesday, surgical; Thursday, surgical; Friday, throat.

DUBLIN.

WEDNESDAY, APRIL 23RD.

ROYAL UNIVERSITY, IRELAND.—Second Examination in medicine.

THURSDAY, APRIL 24TH.

ROYAL UNIVERSITY, IRELAND.—M.B., B.Ch., B.A.O. Exams. commence.

FRIDAY, APRIL 25TH.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of State Medicine. Royal College of Physicians.—8.30 p.m. Papers:—Dr. Maitley: On a Case of Lead Poisoning. Prof. E. J. McWeeney: Concluding Remarks on the Infectivity of the Milk of Cows, which react to the Tuberculin Test but are not Clinically Tuberculous. Sir C. A. Cameron, C.B.: Inspection of Dairy Herds.

Appointments.

BRANDON, B. J., M.D., C.M. Manitoba, Clinical Assistant to the Chelsea Hospital for Women.

CARLESS, ALBERT, M.B., M.S. Lond., F.R.C.S., Consulting Surgeon to St. John's Hospital, Twickenham; and Honorary Consulting Operative Surgeon to the Ealing Cottage Hospital.

DASHWOOD, HOWARD A., B.A. Cantab., M.D. Brux., M.B.C.S., L.R.C.P. Lond., Public Vaccinator for the Parish of Hampton Hill by the Kingston Board of Guardians.

DUNLOP, JAMES CRAUFURD, M.D. Edin., Inspector of Certified Inebriate Reformatories in Scotland under the provisions of the Inebriates Acts, 1879 to 1900; and also Inspector of Retreats licensed under these Acts in Scotland.

HARVEY, FRANK, M.B.C.S., L.S.A., Medical Officer of the Padstow (Cornwall) Fort Sanitary Authority.

HORN, MATTHEW, M.A., M.B., B.C. Cantab., M.B.C.S., L.R.C.P. Lond., Assistant Anaesthetist to the National Orthopaedic Hospital, Great Portland Street, W.

HUNTER, JESSIE B. M.B. Glasg., Assistant Medical Officer to the Lawn Hospital for the Insane, Lincoln.

LARWILL, JOHN, L.R.C.P., & S. Edin., Medical Officer at Boonal, Queensland.

LOGAN, R. B. W., M.B.C.S., L.S.A., Certifying Surgeon under the Factory Acts for the Ashby-de-la-Zouch District of Leicestershire.

MATSON, J. A., B.A., M.D. Dub., L.R.C.P. Irel., Assistant Physician to the Richmond, Whitworth, and Hardwicke Hospital.

PURNELL, RICHARD, M.D. St. And., M.B.C.S., L.S.A., Medical Officer of Health of Wells (Somerset) for three years.

SODHI, BABA M. SINGH, M.B., Ch.B. Edin., Assistant Medical Officer at the Borough Asylum, Portsmouth.

TAYLOR, F. E. M.B., Ch.B. Vict., M.A., M.Sc., M.B.C.S., L.R.C.P. Lond., Pathologist to the Chelsea Hospital for Women.

TUKE, G. M., M.B.C.S., Medical Officer of Health to the Hollingbourne Rural District Council.

Vacancies.

Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer. Salary £130 per annum, with board, lodging, &c. Applications to the Medical Superintendent.

Down County Infirmary.—House Surgeon. Salary £60 per annum, with apartments, &c. Immediate application to Dr. Tate, Downpatrick. (See Advt.)

Durham County Asylum.—Junior Assistant Medical Officer. Salary commences at £150, with board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Durham County Hospital.—House Surgeon. Salary £120, with board and lodging. Applications to Wm. B. Wilson, Secretary, 68, Sadler Street, Durham.

Fisherton Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to Dr. Finch, Salisbury.

Greenwich Union Infirmary.—Second Assistant Medical Officer. Salary £100 per annum, with board, lodging, washing, and attendance in the Infirmary. Applications to Samuel Saw, Clerk to the Guardians, Union Offices, Greenwich, S.E.

Metropolitan Asylums Board, Caterham, Surrey.—Assistant Medical Officer. Salary £150 per annum, with rations, lodging, attendance, and washing.

Sir Patrick Dun's Hospital.—Assistant Physician. Applications to Secretary of the Medical Board. (See Advt.)

Wallasey Dispensary and Victoria Central Hospital, Liscard.—House Surgeon. Salary £100 and board. Applications to Mr. Andrew Lindsay, Newbold, Liscard, Liverpool.

West Norfolk and Lynn Hospital, King's Lynn.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications immediately to the Chairman of the Weekly Board.

Births.

THOMSON.—On April 14th, at 14, Coates Crescent, Edinburgh, the wife of John Thomson, M.D., F.R.C.P. Edin., of a daughter.

SELLORS.—On April 7th, at 14, Emmanuel Road, Balham, the wife of T. B. Sellors, L.E.C.S., L.S.A., of a son.

WISE.—On April 15th, at 23, Plumstead Road, Woolwich, the wife of Harry M. Wise, M.B., of a daughter.

Marriages.

ADDISON—STUTFIELD.—On April 12th, at St. Lawrence, Wormley. Hugh Cecil Addison, M.B.C.S. Eng., L.R.C.P. Lond., of Bedford, only son of William Addison, of Broxbourne, to Margaret Mary, eldest daughter of the late Barton Stutfield, of Wormley.

DAY—COCHRANE.—At St. Peter's Church, Dublin, by the Rev. S. Robinson, M.A., Lieutenant-Colonel J. D. Day, late R.A.M.C., son of the late A. M. Day, Dublin, to Margaret Louise, daughter of Sir Henry Cochrane, D.L., Woodbrook, co. Dublin.

GRINDROD—HIGGINSON.—On April 15th, at St. Peter's Church, Rock Ferry, Cyril John Grindrod, Vicar of Alne, Yorkshire, and of the late Rev. W. Grindrod, to Emily Bingham, daughter of H. B. Higginson, of Rock Ferry, Cheshire.

JAMES—BURNABY.—On April 17th, at St. Stephen's Church, Fiddington, Arthur James, M.D., D.P.H., of 69, Gloucester Terrace, Hyde Park, son of the late John James, of Plymouth, to Gertrude Hilda, daughter of the Rev. Henry Fowke Burnaby, of 29, Kensington Gardens Square.

PISSO—MOORE.—On April 17th, at Holy Trinity, Bournemouth, Ernest Douglas Pisso, M.B.C.S., L.R.C.P., of Langford, Somerset, younger son of Francis Pisso, of London, to Emma Elizabeth (Elsie) Moore, elder daughter of Joseph Moore, Melford Lodge, Bournemouth.

Deaths.

ANDERSON.—On April 12th, at Lochengair, Stonehaven, N.B., John Hector Anderson, M.D. Aberd., aged 48.

FELL.—On April 2nd, at Bibiana, Ashantee, in his thirty-first year, William George Fell, M.B., B.S. Durham, eldest son of John Fell, 5, Eslington Road, Newcastle-on-Tyne.

MACGREGOR.—On April 12th, suddenly, at 8, Queen Street, Berkeley Square, London, Alexander MacGregor, M.D. Aberd., M.B.C.P. Lond., J.P.

MAYO.—On April 7th, at Spitalgate House, Grantham, Eleanor, wife of A. C. Mayo, St. George's Park House, Great Yarmouth, aged 59 years.

SHELLSWELL.—On April 13th, at Alkerton, William Arthur Shellswell, M.B.C.S., L.R.C.P. Lond., formerly of Shenington, aged 39 years.

WILLIAMS.—On April 10th, at Hill House, Clay Cross, in his thirty-ninth year, Evan James Williams, L.R.C.P., M.B.C.S., youngest son of the late James Williams, Esq., J.P., Cardigan.

Paris Clinical Lecture.

THE

ETIOLOGY AND TREATMENT OF OBESITY.

By PROFESSOR DE BOVE,
Physician to the Paris Hospitals.

[SPECIALLY TRANSLATED FOR "THE MEDICAL
PRESS AND CIRCULAR."]

We have on various occasions discussed the treatment of adiposis or obesity in connection with the case of a man who, at the time of his admission, weighed 147 kilogrammes, but under a specially devised regimen lost fifty-three kilogrammes in less than a year. I will not dwell upon his history, which I laid before the Academy of Medicine last year, and which was published in detail.

I think it well, however, to draw your attention once again to the problems which are raised by the study of obesity, especially in respect of its pathogenesis and treatment. An opportunity is afforded me by a patient whom I have been treating for nearly a year, whose clinical history I will first of all lay before you.

The patient, a man, *æt.* 44, was predisposed to obesity by his hereditary antecedents; his father was gouty, his mother and grandfather were obese. Lastly, a great-grandmother on the maternal side was obese to such a degree that towards the end of her life she could not enter any public vehicle, and did not dare to go out because everyone turned round to look at her. With such antecedents the man required a strictly moderate diet and a great deal of exercise to escape obesity. He, however, ate freely. He himself described his appetite as good, and passed for a high liver. He had a special predilection for fat meats, farinaceous food, macaroni, pudding, pastry, sweetmeats, &c., not to mention bread, of which he consumed large quantities.

The results of this mode of living were the more serious since the patient, whose profession was of a sedentary character, took very little physical exercise. He married early and passed most of his time at his own fireside, rarely going out. I am of opinion that to this laziness, due to his constitution, is due in great measure his regularity of conduct. Rather delicate in his youth, he only commenced to grow corpulent towards his eighteenth year, at which period his obesity was not remarkable. Corpulency in infants is generally due to special causes which do not concern us at the present moment. As he was not regularly weighed I cannot trace his progressive increase in weight; but when I saw him in March, 1900, his corpulency had become very embarrassing.

He weighed 147 kilos, a weight too great for his waist, which measured 1 m. 66, and which only ought to support about 66 kilos; thus he weighed 51 kilos beyond the normal.

This degree of obesity not only affects the agility and external shape but also and above all causes functional disturbance in the various systems. More especially obesity obscures the mental faculties.

Those suffering from obesity had not a good name in the time of the Lacedemonians, who thought them wanting in intelligence and memory, and who excluded them from all positions in the State. Shakespeare did not think any better of them when he wrote—

"Fat paunches have lean pates."

Our patient had not fallen as low as this, although he was a victim of marked intellectual apathy, and suffered from attacks of genuine narcolepsia. Retiring to bed at 10.30 p.m., he sleeps till 2 a.m.; from this time his rest is usually disturbed, and he gets up four or five times an hour; he ultimately leaves his bed at 6 a.m., but a few minutes after he is seized by uncontrollable drowsiness, and goes to sleep for several hours on the sofa.

During the day, whilst writing, he is often seized by an irresistible desire to sleep, from which he is aroused by his pen falling from his hand. It is not unusual for him to fall into deep sleep in the middle of a conversation, his friends being obliged to pinch him or slap him on the shoulder to awaken him.

It even happened occasionally that he went to sleep standing and fell down. Some of these falls had serious results; once he broke a pane of glass against which he was leaning; another time he fell down stairs and sustained a contused wound, of which he still bears the marks.

The cerebral troubles which worried him, and his family even more, were not the only source of anxiety. The least movement became troublesome, and caused genuine fatigue; it was very hard work for him to have to go up to his room on the fifth floor. Other actions calling for much less energy had become fatiguing; for instance, he could no longer lift his arms up, and it was only with great difficulty that he could wash his neck; whenever he went into a urinal he was obliged to lean against the walls. The respiratory movements were performed very inadequately, and the least effort provoked dyspnoea.

The fat had doubtless invaded the heart as it had invaded the muscles of external movement and the respiratory muscles, for the pulse was soft, compressible, and slightly quickened; the fatty overcharge of the heart was probably, to a certain extent, the cause of the dyspnoea under slight provocation. Digestion was slow and accompanied by gaseous fermentation, which obliged the patient to loosen his waistband during the period of digestion.

As to the sexual functions it is hardly necessary to speak of them; you know the proverb, "A good cock is never fat"; the Latins, speaking of corpulent people, say they are "*... in venerem segnes nocturnaque bella.*"

Hippocrates had already noticed that among the complaints caused by too pronounced corpulency must be mentioned sterility. This is a fact applicable to the females of all other species of animals as well as to the human species. The distended skin had become very thin and was readily irritated; the patient had a very pronounced intertrigo of the genital folds and of the gluteal folds, and some patches of eczema on his legs. The urine contained neither sugar nor albumin.

Thus our patient presented in a marked degree all the symptoms of obesity and all the disturbances known to arise from the fatty invasion of the various tissues a

difficulty in the external movements, shallow respiratory movements and defective peripheral circulation with cerebral troubles.

This abnormal adiposity had a predisposing cause—heredity; there had been several members of the family who had suffered from obesity. The precipitating causes were too copious nutrition and insufficient exercise; the patient accumulated fatty reserves, his income being much larger than his expenditure within the organism.

The real, determining cause had up to now always escaped us, for though we can always make a fat man lose flesh, we cannot make a thin man gain in weight. I have seen many thin patients resist all sorts of treatment, having for object to make them grow fatter. We do not know, therefore, what it is that makes a man obese, although we know that the tendency is transmitted by heredity. That, indeed, is the extent of our knowledge.

We are prone to mask our ignorance of causes by emitting theories. Theories, indeed are, admittedly, indispensable to the progress of science; I will mention one of them; it does not pretend to be definitive—no theory can be—it is sufficient that it accounts for the clinical facts observed in this connection.

To my mind, it is due to a peculiar state of the nervous system, by which I mean that the quantity of nourishment that we ingest every day is not exactly proportionate to our wants. When we overstep the maintenance ration, a certain portion of the food absorbed is destroyed by a series of changes and oxidations. If it were otherwise, a person who overstepped, however little, his daily maintenance ration, would increase in weight indefinitely. There is, however, a regulating apparatus which brings about the destruction of substances absorbed in excess of requirements, and which moderates combustion during the periods of fasting, so as to maintain the equilibrium of nutrition. Now every regulating apparatus, in whatever way it performs its function, belongs to the nervous system; therefore it is the nervous mechanism that is disturbed in corpulent people.

The influence of the nervous system over nutrition is established by observations so numerous that our only difficulty is to make our choice.

We have seen hysterical subjects completely deprived of nourishment who could reduce their oxidation to a minimum, eliminating only seven grammes of urea per day and only losing 4,300 grammes weight in fifteen days. In opposition to this, I have known a woman, the prey of a violent grief, who took food every day at each meal-time, small in amount it is true, and who lost 15 lbs. in two weeks, thus losing more than a patient on starvation diet. The first observation proves that under the influence of the nervous system the expenditure may be reduced to a minimum; the second that under the same influence denutrition may be produced, followed by rapid emaciation.

Thus there is a nervous apparatus which regulates the processes of combustion, either accelerating or slackening them, which causes the oxidation of the absorbed aliments or provokes their deposition in the form of fat.

That which I attribute to a nervous trouble, M. Bouchard describes as due to mere slowing down of nutrition. From his theory to mine is but a step, or more exactly, it is the same theory formulated in another way. Obesity is always due to a slowing down of nutrition. But we must, I think, to explain this slowing down, take into consideration the nervous trouble, the nervous system being, as I have pointed out, the ultimate regulator of nutrition.

This nervous trouble is primary and secondary; primary when it appears under the influence of an unknown cause, secondary when it appears as the result of an easily determined cause, such as gout, diabetes, chlorosis, the menopause, arrest of the development of the testicles, myxœdema, &c.

If obesity be due to a disturbance of the regulating apparatus of combustion, its treatment will comprise two periods. I will call the first the period of insufficient nourishment, the second, the period of voluntary regulation. In order to make a patient lose

weight he must be put on a low diet; his income must be cut down so as to compel him to use up the reserves which he has accumulated by a sort of exaggerated economy. But what is a low diet? Evidently one which is not sufficient to cover the output of the organism; and this leads us to estimate of income and expenditure.

The food which we take sustains the body, enables it to grow, maintains animal heat, in addition to voluntary expenditure of energy.

We will dismiss growth, which only takes place at certain ages. We will assume that we are dealing with adults. The quantity of nourishment necessary for the physical maintenance of the tissues is really rather small and may even be dismissed from consideration in certain cases. Most of the food is employed in the production of heat and muscular energy. You are aware that heat and energy are identical terms, therefore it follows that the value of a food is represented by its thermic value and the maintenance ration can be represented by a given number of heat units. This is reckoned as 43 units per kilogramme for a man at rest, and a quarter more, that is to say, 54 units, in the case of a man doing hard work.

Thus nutrition is insufficient when it is obviously below 43 units per kilogramme of body weight. I say "obviously" below because there is a certain degree of automatic adjustment. A person who is receiving less nourishment diminishes automatically his combustion, just as a man whose income grows smaller can still maintain the equilibrium of his budget by reducing his expenses.

Thus the nutritive value of a substance may be expressed by a thermic formula. Now the number of units furnished by 1 gramme of a nutritive substance is, for carbo-hydrates and albuminoids from 4 units, and for fatty substances from 9 units. All foods can take the place of each other in isodynamic proportions, and whatever be their nature, are apt to give rise to the formation of fat.

There are nutritive substances which cannot directly produce fat and yet cause fattening; as an example I will mention alcohol, which has a high thermic value, for the combustion of 1 gramme of alcohol produces 7 units. But a man who takes alcohol fattens, because in burning the alcohol which furnishes the units necessary to his maintenance, he does not burn the other food stuffs, which therefore remain in excess, and are used up in the formation of fatty deposits in the tissues.

This makes it easy for you to appreciate the nutritive value, or if you prefer it, the calorific or "fattening" value (excuse this barbarism) of the various foods, by referring to one of the tables, among others that of König, which indicate the chemical composition of each foodstuff.

By remembering that the maintenance ration is from 43 units per kilogramme at rest, it is very easy, if you know the thermic value of a food and the weight of the subject, to calculate his maintenance ration.

Take, for example, a man who weighs 70 kilogrammes. His maintenance ration is $70 \times 43 = 3,010$ units. Suppose a man is fed on milk which contains per 100 grammes 3.50 grammes of albuminoids, 4.90 grammes of carbon and 3.70 grammes of fat. We can take the albuminoids and carbo-hydrates together since they possess the same calorific value (4.1), which makes 3.50 grammes + 4.90 grammes = 8.40 grammes. Their combustion will furnish 8.40×4.1 grains = 34.44 units. The combustion of fatty matters will give a further $3.70 \times 9.3 = 34.41$ units.

Adding up these two quantities we find $34.44 + 34.41 = 68.85$ units, that is to say, the combustion of 100 grammes of milk furnishes 68.85 units.

Since 3,010 units constitute the full ration of a man weighing 70 kilogrammes, by an easy calculation it will be seen that he requires to take rather more than 4 litres of milk a day.

Remember also that the combustion of the fat in milk on the one hand and the albuminoid constituents and carbo-hydrates on the other, represents very nearly the same number of units; thus the skimming which takes away the fat diminishes by one-half the nutritive value of milk, and skimmed milk is, therefore, an ex-

cellent nourishment for the cure of obesity. If the milk is not skimmed a man of 70 kilogrammes would have to take less than 4 litres in order to get thin.

A calculation might easily be made for all kinds of food on similar lines. You need only refer to König's table and determine the thermic value of the ingested nourishment.

These calculations were necessary in order to establish the theory; but in practice it is not necessary to work it out on every occasion.

In order that a person may lose weight he must be put on an insufficient diet, without, however, allowing him to suffer from hunger or indeed from even the slightest constitutional disturbance. To assuage hunger whilst on an insufficient diet, all we have to do is to resort to aliments possessed of low thermic value, even when given in large quantities. I usually order milk, preferably skimmed, mixed with water or tea, green vegetables (cabbage, spinach, salads), and fresh fruit.

A peculiarity to which I wish to draw your attention without being able to explain it, is that persons who feed on fresh vegetables, raw meat, &c., in fact, on what I may call living substances, are much better able to support an insufficient diet than others.

I allow the patients to drink as much as they wish, and this for several reasons. The pangs of hunger are not very painful, but those of thirst are frightful. When patients are restricted as to eating, it is necessary to let them drink as much as they wish. Since water washes away the products of organic combustion we cannot with impunity, by reducing the intake of water, reduce the secretion of urine, in certain subjects.

Privation of drink may provoke attacks of nephritic colic, to which obese people are specially predisposed. Moreover, drink does not fatten (I am speaking of water, and not of alcoholic drinks). Observations carried out on a hysterical subject and on one of ourselves, showed that equilibrium of weight having been obtained, it was not disturbed by variations in the quantity of water ingested.

This statement appears to be in contradiction with what one observes in persons put on a dry diet. These lose weight, it is true, but this is because when deprived of drink they eat less. Place an obese person before an appetising meal, allow him to eat as much as he wishes of each dish but forbid him to drink, and you will find that he will not do justice to the food. The privation of drink, therefore, acts indirectly by diminishing the appetite.

Great care should also be taken to keep the bowels freely open. The cure is accelerated by the use of mild laxatives, which get rid of a part of the surplus food, for a person is not fattened by what he swallows but by what he digests, and purgatives provoke slight indigestions which cause the stools to eject all that is not already digested.

Having enunciated these principles, we will now proceed to see how they apply to the patient. When he was first put under treatment on March 21st, 1900, he weighed about 235 lbs. He refused milk, which he loathed, and took as much fruit and greens as he cared to. When he was hungry he ate an orange or a banana, and drank weak tea. Before each meal he took 10 drops of tincture of aloes to keep the bowels free. Between March 21st and April 23rd he lost 22 lbs. in weight.

At this stage I allowed bouillon freed from fat, and coffee, after lunch. The treatment was continued till June 30th, by which time the patient only weighed 189 lbs. From June 30th to August 10th the treatment was relaxed owing to his going into the country; but even then, on his return to Paris, his weight had further fallen to 178 lbs. Although from this time the treatment was never strictly followed, his weight had fallen to 159 lbs. by December 9th, to 157 lbs. by December 14th. Since then it has risen to 163 lbs. Thus our patient lost 72 lbs. in nine months, i.e., nearly a third of his weight, or more than 125 grammes a day. The loss was more rapid at the commencement, as it always is.

These results are similar to those obtained in the case of the first patient, whose case I alluded to earlier. He discontinued all treatment, and has only increased a few pounds in weight. His actual weight

is still 50 kilogrammes less than his weight at the time when he came under treatment.

I could relate many more observations. I will, however, only relate one observation made by a doctor, *et. 39*, on himself. He belonged to an obese and gouty family. Under the influence of a restricted diet he lost more than 30 kilogrammes in fourteen months; weighing at the commencement 119.5 kilogrammes, he now weighs 89.4 kilogrammes.

Breakfast.—A cup of tea with milk.

Lunch.—One or two slices of meat, a little vegetable, 100 to 150 grammes of bread, a little cheese, as much fruit as he wished, and a cup of black coffee without sugar.

Dinner.—Half a litre of sweetened hot milk, 30 to 50 grammes of bread, and as much fruit as he desired.

The loss in weight was borne without fatigue. The only inconveniences caused were five or six violent attacks of gastric acidity, and these were overcome by chalk and bicarbonate of soda. There was at no period any constipation; on the contrary, after the milk at night there was moderate diarrhoea.

The treatment was not difficult to follow. The patient himself affirmed that he followed it with pleasure; the marked improvement observed at the end of ten days encouraged him greatly, and he affirms that he never experienced either lassitude or repulsion.

The majority of people are not so easy to treat, and satisfactory results are only obtained under certain conditions. One of the first is to compel the patient to eat by himself, for it is painful to be restricted when surrounded by people who are eating their fill. It is also preferable, when possible, to place the patient in an institution; he will not be exposed to temptation and banter.

As to the permanence of the results, this depends on the subject. Once the loss in weight obtained, the patient ought to follow a modified treatment, based on the weighings. His nervous regulating apparatus no longer acting normally he must substitute voluntary regulation for automatic regulation.

I know of no drawbacks to this treatment. Certain patients complain of disagreeable sensations, the more so in proportion to their lack of will power.

I ought, perhaps, to refer to physical exercise. This often gives very unexpected results. Theoretically, exercise stimulates combustion, but it is not unusual for the appetite of corpulent people to increase after prescribed exercise; and a more copious nourishment is followed by a further increase of weight. To cause loss of weight exercise would have to be pushed to the point of exhaustion, and this can never be advised.

Now, as to the thyroid treatment. This certainly causes certain people to grow thinner, but the marvellous results obtained by it in certain cases all occurred in individuals whose obesity was in direct proportion to the inadequacy of the thyroid functions, and represented a sort of mild myxœdema. The thyroid treatment, therefore, is indicated in but few cases of obesity; in fact, it is dangerous, because it sometimes gives rise to grave cardiac disturbances; it has even caused death when incautiously resorted to.

The patient whose history I have given in detail, had two years previously tried the thyroid treatment. He followed the treatment for eight days, but he was attacked by palpitation, his pulse rose to 100 and even 110 and on the advice of his doctor he discontinued the treatment. The acceleration of the pulse continued for a further eight days. The loss in weight caused by this treatment would at most have been 2 or 3 lbs. per week. Lastly, even if successful, when the thyroid treatment is discontinued the obesity infallibly returns.

By conforming to the rules which I have just laid down, you will assuredly be successful in curing obesity, but do not forget that this success depends much less on you than on the determination of the patient. There are some who will never be cured, because they will not make up their minds. This is what happened with a patient of mine who declared that she would not follow my treatment because she got fat on it and that as a matter of fact, the less she ate the fatter she became. With such patients nothing can be done.

RHEUMATIC NODOSITY IN INFANTS. (a)

By HERBERT JOSIAS, M.D.,

Physician to the Bretonneau Hospital, Paris.

THERE are two varieties of rheumatic nodosity: the first is dependent on chronic rheumatism, and is, as a rule, independent of articular inflammation; the second is an epiphenomenon of acute articular rheumatism, and forms with chorea one of the most curious sequelæ of infantile rheumatism. This latter form has been fully described, in France, by Professor Jacoud, and vaguely written of in Germany by Froriep (1863), more clearly in England by Hillier (1868). But the first clinician to clearly demonstrate that the nodosities were of rheumatic origin was Meynet, of Lyons (1875). Afterwards Rehn (1878), Davaine (1879), Hirschsprung, Troisier and Brocq (1881), Briessaud (1886), Barlow and Warner (1887) contributed papers supporting Meynet's theory.

Two cases of the disease were admitted to the Bretonneau Hospital. The disease is not common, and we, therefore, thought the clinical notes worth printing.

The first case: D. Albert, æt. 1½, was admitted on May 8th, 1901. The patient's father enjoys good health; the mother is in good health, but she is nervous, and occasionally suffers from joint-pains. He has one brother, who enjoys good health.

At eight years of age the patient had an attack of measles. He has had no other sickness; but he is nervous, impressionable, and sensitive to a fault. The present illness commenced suddenly, one month prior to his entering hospital. The child was seized with a sore throat, with a high fever, and a swelling of the maxillary and sub-maxillary regions which extended to the ears. Two days afterwards an eruption followed which, commencing at the face, spread to the neck, trunk, and the whole body. It consisted of reddish-copper-coloured plates, which did not run together but were separate, each patch being surrounded by a ring of healthy skin. The eruption was associated with an intense itebiness of the skin; and though the rash continued on the body for eight days the individual patches appeared, blurred and faded more than once during that time. Eight days after the total disappearance of the rash the pains in the joints commenced. They commenced in the arms, beginning in the elbow-joints and then attacking the shoulders. Shortly after the knees and the ankles became the seat of pain. These pains were unaccompanied by redness, swelling or movement of the joint. He now complains of palpitation of the heart, and of a pain in his præcordial region.

Eight days before coming into hospital it was noticed that his movements were irregular, choreiform, and he complained of a pain over the seventh cervical vertebra of a very severe character, intensified by pressure. The pain was well marked all over the cervical spines, and the least movement of the head caused agony. This spinal pain caused the physician in attendance to suspect Pott's disease.

The choreiform movements were intense, so much so that there was considerable difficulty in feeding this child. The arms were more affected than the legs, withal the patient could not walk. His speech was also affected, so that it was with difficulty he pronounced his words. At this time the parents noticed little knot-like bodies under the skin, and a peculiarity of the child's hands. The four outer fingers were firmly flexed on the palm of each hand.

On admission the little patient was found to be greatly emaciated, weighing only 26 kilos; his skin was of a uniform brown colour without any rash. His parents said the child's skin was always dark-coloured. The head and the superior and inferior limbs are in a continuous state of choreiform movement. His head was constantly moving from side to side and the muscles of the face ever twitching in irregular grimaces, which

greatly distorted his features. The arms were always moving, alternating pronation and supination. The shoulders were being shrugged up and down. It is with difficulty a glass can be carried to his mouth, or a drink be given to him.

The movements of the legs are not so violent or incessant. Resting unobserved the movements are continued, but they become worse when he sees he is noticed. Under no circumstances do they cease, and the child is deprived of sleep by them. He speaks in monosyllables. Deglutition is not affected. Both hands are flexed strongly, phalanges on phalanges, and even the metacarpals are in a position of flexion. The thumb on being drawn out will remain in the normal position for some time. On attempting to draw out the other fingers the action is resisted by a force resembling that of an elastic band. Any attempt to overcome this resistance causes a choreic crisis and great pain. No deformity of the phalangeal articulations is to be found. On opening the hands nothing abnormal is to be seen, the joints of the whole body move freely without crepitation, swelling, or redness. A careful examination will, however, detect slight nodosities at the extremities of the members.

All these nodosities appear over the skin, which, however, moves freely over them; their deep attachment seems to be to the tendons, or fibrous sheaths, or to the periosteum.

In the first group of these the nodosities move freely, moving with the tendon of the finger; in the other cases they appeared to move more with the bone. Slightly painful on pressure, these nodosities varied in size from that of a grain of hemp seed to that of a lentil, though at the seventh cervical spine two were found that were as big as a small hazel nut. The colour of the skin immediately over them is normal, but when stretched they appear under it as small white patches or points. In number they are very considerable, fully 250 being present; in the neck they in some places have formed masses of nodosities from the union of their margins.

Their distribution is as follows:—Face, none; phalangeal articulations, right side, 2 to 4; left side, 2 to 3; metacarpo-phalangeal articulations of the thumb, right side, 4; left side, 4 to 8; the metacarpo-phalangeal articulation of the index finger, of the right side, 8; of the left side, 4 to 8; the metacarpo-phalangeal articulation of the other digits, on the right side, 4 to 5; on the left side, 4 to 8; at the extremity of the metacarpal bones on the tendon of the common extensor of the fingers, on the right side, 5 to 6; on the left side none; at the level of the metacarpal extremities on the exterior indices, on the left side, 15; on the site of the long abductor on the metacarpals of the right side from 5 to 6. In short, there are 60 to 70 nodosities found on the upper extremity of the right side, and some 80 on the left side. On the inferior extremities there were 60 on the right side and 70 on the left side. Some 5 or 6 were found in the helix; in the temporal, the temporo-parietal and temporo-occipital regions, nodosities, resembling grains of shot, were found; at the great occipital protuberance two nodosities that had attained the size of a small hazel nut.

A few other nodosities were found on the vertebral column and at the points of the pelvis. The lymphatic ganglia are not increased in volume.

An examination of the child further showed the following:—

The apex beat of the heart was felt in the fourth intercostal space, with a purring tremor, and a great blowing sound as if a jet of steam was blown out; this was heard in the back of the chest. The pulse was 80, full and regular.

The tongue is slightly furred, there is loss of appetite, the bowels are regular. The liver and the spleen are normal in size. There is nothing special to note regarding the lungs.

Prior to the present the child never suffered from any nerve troubles. The corneal and pharyngeal reflexes are absent; there are no hyostrogenetic points nor troubles of sensibility. The urine containing neither sugar nor albumin. The temperature which on the child's admission was 104°F., fell to normal, at which it has remained.

(a) A paper read before the National Congress of Obstetrics and Pediatrics at Nantes.

TREATMENT.

The Treatment consisted of thirty grain doses of the salicylate of soda and seven and a half-grain doses of bromide of potassium. May 13th.—The patient is better, the choreiform movements are less marked. The child is able to feed himself, but he is not able to walk. The abnormal flexion of the fingers continues; complete extension is possible, but very painful. The general condition is good. The nodosities remain as described. May 20th.—Complete cessation of the choreic movements. The patient is able to rise up from his bed and walk alone. He is in good spirits. The flexion of the fingers is less marked.

The nodosities which existed on the tendons of the flexor muscles of the fore-arm in the position of the wrist are notably less in size.

The treatment now consists of small doses of arsenite of sodium, and a discontinuance of the salicylate of sodium.

May 28th.—The choreic movements have ceased, and the boy passes the day playing with his companions. The nodosities are disappearing. We cannot find any on the palmar tendons, or those of the fore-arm. The nodosities found at the digital articulations have passed away, those at the elbow still remain. At the cervical prominence the nodosities are still numerous, but they are more easily moved. The two large nodosities on the occiput are in no way lessened; those on the ear are less prominent. The fingers are extended more easily. Cardiac trouble persists; weight, 28 kilos.

June 2nd.—There are not one-tenth of the number of the nodosities on the superior extremity. A fresh one, however, was found on the wrist.

The nodosities on the inferior extremities now number 7 or 8 on the right and 10 on the left side. The nodosities of the ear have disappeared. On the occiput the two nut-like nodosities have not lost bulk, but they are less adherent to the bone. In the temporo-parietal and temporo-occipital regions the few nodules seem to have increased so much that these regions are studded with them.

The general condition continues good. On June 5th we ablated one of the occipital nodes. On raising it we found the consistence of the node to be soft, although it felt, before cutting through the skin, of bony consistence. June 18th.—The nodosities have disappeared from the skull, and those of the extremities are almost all gone. A fresh nodosity has appeared at the base of the right thumb eminence; it is as large as a pea. The pathological condition of flexion of the fingers has altogether ceased.

July 6th.—A fresh crop of nodules has appeared; they number some 20, and are found at the metacarpophalangeal articulations, on the elbows and on the knee-pans. The heart trouble persists. The general health of the child is good, and to-day he quits the hospital.

Second case: F. M., set. 13, entered hospital on June 29th, 1901. His father enjoys good health and never had an attack of rheumatism. His mother died of tuberculosis. His maternal uncles are living and are healthy. The infant had good health for the first two years of his life, when he had a severe attack of rheumatism, which became localised in the wrists, elbows, and knees. The child was confined for eight days to bed, but the pain did not disappear for four months. One month after the beginning of the rheumatic attack the patient had a crop of nodosities at the points of his elbows and knees, and as he now presents, they remained for two months and then they faded away. Five months after the attack the little patient had a fresh one, the severe pains being most marked in the ankles, knees, wrists and elbows. The articulations were neither red nor swollen, and the child continued to walk about. Fifteen days afterwards there appeared a crop of small nodosities. Two months after he had an eruption of red plaques at the groin, followed by shortness of breath.

On admission the child was found to be very anæmic, emaciated, and on his chest and belly a circinate erythema, which appeared to be fading. At the fold of the groin there were taches, purple and red, apparently of different ages. An examination of the joints showed the

presence of numerous nodosities. Their size varied from that of a grain of hemp seed to that of a lentil. They are subcutaneous, easily movable, and attached to the deeper tissues. They are not at all painful on pressure. The child complains of pains in the knees when he has walked for some time. The joints are neither red nor swollen, and passive movement gives no pain.

A general examination gave the following results:—Tongue moist and red, appetite good, bowels regular, lungs normal. Heart apex beat in the fourth intercostal space, a finger-width beyond the left nipple. The apex stroke strong and free of any purring sensation. On auscultation a double bruit was found, the first is prolonged to the second sound and is badly masked; the second is heard best at the base and is continued in the direction of the aorta. The pulse is full, bounding, 80 in the minute, and the papillary pulse is very clearly marked on the nails. Temperature normal. Urine free from albumin. Treatment, thirty grains of the salicylate of sodium.

July 10th.—The nodosities lessening in number and size.

August 18th.—The child convalescent and all nodosities disappeared.

Histological examination of the occipital node excised from the first patient:—A fragment of the node was fixed by the liquid of Muller and then mounted in collodion, coloured by eosine and hematein.

A section through the thickest part of the nodosity showed that the structure was not uniform throughout. Certain parts consisted of a lax areolar tissue of a rose colour, and others of a dense tissue of a dark colour. Elsewhere we found the cells of the same type ranged in series and separated by very fine fibres. The intercellular tissue in places appeared homogeneous, and in others slightly fibrillar. In the midst of the fibrous tissue of the different varieties we found:—

1. Islets of cells irregularly disposed, some in strings, others in circles, regularly irregular.

2. Numerous vessels found permeating the cell masses: arterioles with one wall greatly thickened and their lumen almost occluded. In no part of the tissue did we find necrosed cells, and cartilaginous tissue was absent. At one point in the substance red cells distended the meshes of the tissue.

BACTERIOLOGICAL EXAMINATION.

A fragment of the nodosity, fixed and mounted in paraffin, was examined bacteriologically. Our results were negative. The specimens were coloured with thionine, by the gentian violet dissolved by the method of Gram. Of the 75 cases published of nodosity of the joints, 60 occurred in subjects under 20 years of age, and the greater number of them occurred in girls. Seldom do the nodosities appear during the first attack of rheumatism, as in our first case. They usually make their appearance in the second or some succeeding attack.

The following table, which we borrow from Garrod, gives the points of selection of the nodosities in 50 cases:—About the elbow in 37 cases; hand, 30; knee, 20; ankle, 16; spine, 10; head, 10; shoulders, 9; shoulder blades, 6; pelvis, 7; clavicles, 5.

Our first patient had nodosities on the pinna of the ear. This position is unusual, we find it mentioned once only (M.M. Trosier and Brocq). The nodosities are neither adherent to the skin nor to the deep part; their connection to the periosteum is not close enough to consider them of exostotic genesis. In size they range from the size of a head of a pin to that of a hazel nut. Occasionally they attain the size of an almond or of a walnut. The very largest are very easily moved about. In consistence they are firm, elastic, and sometimes truly bony. Nodosities nevertheless sometimes consist of a soft substance which offers little resistance to the pressure of the finger. This difference in the character of the nodosity is principally due to the growth or otherwise of vessels in its substance and the thickening of its walls. The number of the nodosities in any given case is very variable. In our first case the number was large, in the second there were not nearly

as many. Indeed, on the extremities in the first case we counted 250.

The first of these cases had on the pinna of the ear two nodosities. This localisation is unusual; we found only one such case recorded, that of M.M. Trosier and Brocq. The nodosities were not adherent to the skin nor to the deeper tissues; all their attachments were too loose to justify them being considered as exostoses. Their size ranged from that of a head of a pin to that of a hazel nut. Occasionally, however, they attain to the size of a sweet almond or that of a walnut.

The largest of them are readily moved to and fro; they give on palpation a sense of containing semi-fluid contents, which is not present in those of a small size. Their consistence is firm, elastic, and sometimes feels as if osseous. This firm feel of the nodule prior to its excision is principally due to the thick walls. In number they usually average thirty. On our first patient we found more than 250 on the extremities alone. At the cervical prominence they were so numerous that they became confluent; a very exceptional condition. In one case, that of Fletcher, there were 140.

The nodosities may appear when the joint pains are dying away, or they may not appear until convalescence. The case of Meyer is not an exception to this rule; the nodosities, it is true, preceded the rheumatic attack by twenty days, but before they came the patient had suffered from joint pains. Nodosities appear suddenly in a good large crop, which from time to time is succeeded by smaller crops which appear irregularly. The duration of the nodosity is very variable, some come and go so quickly as to be named ephemeral. Others remain a long time, eighteen months in some cases, and in one case, Duckworth's, they lasted for thirty months. As a rule they persist for one or two months. Those which remain a long time, finally fade away without leaving any trace, and they never undergo suppuration.

The articular phenomena which precede nodosities are, as a rule, slight, the acute form is the exception. Sometimes there are muscular pains and no joint pains, and occasionally they co-exist with rheumatic phenomena. Cutaneous eruptions are frequently present. They consist generally of polymorphic erythema. In our cases urticaria and purpura were present.

The flexion of the phalanges on the phalanges and on the metacarpal bones, which was so marked a feature in our first case, is noted by three authors as having occurred in their experience. Chorea is a more frequent complication; it has been noted in five cases. In general it assumes a grave form and may precede or follow the eruption of the nodosities.

In our two cases the heart was affected; in one with mitral insufficiency, and in the other with aortic insufficiency. This frequency of cardiac lesions in cases of nodosities has not escaped the notice of authors who have written on the subject. Cardiac troubles seem to occur during infancy only; they were found in everyone of the sixty recorded cases in patients under twenty years of age; but in those over twenty years of age the cardiac lesions were found but four times only.

This correlation of the attack of nodosities with cardiac disease during infancy requires of the physician a careful examination of the heart in every case of the disease. Hirschsprung cites a case in point. A patient, *et. 9*, was brought to hospital for a tenotomy of the tendon Achillis. He happened to observe a nodosity, about the size of a pea, over the fourth dorsal vertebra of the child, and at once auscultated the heart, where he found a marked case of mitral insufficiency.

Endocarditis is the most common form of cardiac lesion found in these cases, its usual site being the mitral valves. Pericarditis is unusual, it occurred in six cases only. Endo-pericarditis is still more infrequent. Weilh and Galavardin report a good example of interstitial myocarditis. This association of cardiac disease with nodosities ever darkens the prognosis in infancy.

Cheadle did not hesitate to say:—"I regard an eruption of nodosities as almost equivalent to a sentence of death. It tells of an affection of the heart against which we are powerless, one which is infallibly going to a fatal termination."

The cardiac affections are not always quickly fatal; in fourteen cases of the sixty reported in childhood death did not take place for a considerable time. Our cases go to shew that Cheadle takes too gloomy a view of the prognosis.

Histological examination of the nodosity is too often neglected. The authors who found them to contain some hyaline cartilage interspersed among the fibrous tissue are Angel Money, and Grawitz. Masses of necrotic cells were found by Bang and Nepveu. In our cases the characteristics were the many thick-walled vessels, the groups of young cells, and a great nest of vividly coloured cells. Our bacteriological examination of the nodosal contents gave negative results.

Nepveu is said to have found in one case bacilli and micrococci, but his observations were made on a patient who at the time was suffering from acute endocarditis, and are therefore of little value as to the bacteriology of nodosities.

The most plausible hypothesis of the disease is that which likens the subcutaneous nodosity to the nodosity found on the mitral valves in endocarditis. In both cases the cellular proliferation is due to the same cause. It is, however, strange that the appearance of the endocardial nodosities and of the subcutaneous ones does not synchronise. Endocardial nodosities may exist without any subcutaneous ones appearing. But subcutaneous nodosities are never present without a similar condition co-existing in the endocardium.

The intimate association of endocarditis in youth with chorea has long been known, and in three of the reported cases of nodosities chorea appeared as a complication.

TWO CASES OF MULTIPLE TELANGIECTASES ASSOCIATED WITH RECURRING EPISTAXIS.

By R. H. KENNAN, M.D., M.Ch.,

Assistant Surgeon to Sir Patrick Dun's Hospital.

Two patients, John D. and Maggie D., twins, *et. 10*, were brought by their aunt to the Out-patient Department of Sir P. Dun's Hospital last autumn suffering from a mild attack of influenza. Multiple telangiectases on the faces of both children were at once noticed, and, replying to inquiry regarding them, the children's aunt stated that this condition was first observed about four years before, immediately after the children had had measles and had returned from the fever hospital. The little *nævi* were scattered thickly over the face without forming any definite pattern in their arrangement. Each group of capillaries formed a spot as a rule distinct from neighbouring groups. The spots were of various sizes. They formed no elevation, they seemed to have avoided the cutaneous margins of the eyelids, openings of the anterior nares and the ears. They presented no similarity to the common *nævus araneus*, the central vein which is usually such a conspicuous feature of these was not present in any, nor were the venules so definitely arranged in a radial direction. The boy had a "capillary" *nævus* behind his left ear measuring about half an inch by three-quarters of an inch area, and a larger one on his back in the sacral region; these had been noticed immediately after birth, and were then of about the same size as at present. Their aunt did not think that any fresh spots had appeared during the last four years, but it had been observed that they became more evident at times, particularly when the children were indisposed.

Opportunity has arisen since they came under observation of proving the truth of this, but the difference in appearance seems to be due to the more marked contrast afforded by the intervening areas

becoming paler rather than any great tendency on the part of the nævi to become brighter. In a few places small pigmented areas were detected by Dr. Walter Smith, who kindly saw the cases with me, chiefly on the face of the boy, lying among the telangiectases; they varied among themselves in depth of brown coloration. It was stated that the boy's nose frequently bled, and that he was constantly "picking" it. Examination of the nose revealed no areas of marked abnormal vascularity. A few spots were seen on the mucous membrane of the lower lips of both children.

While these cases were under treatment a paper by Professor Osler in the *Bulletin of the Johns Hopkins Hospital* for November, 1901, entitled "On a Family Form of Recurring Epistaxis, associated with Multiple Telangiectases of the Skin and Mucous Membranes," came under my notice. In the opening paragraph it is stated that "The association here described is rare, as, after a careful search through the literature, I can find but one reference to a similar case." Subsequent to reading Professor Osler's very interesting account, inquiry was made as to the occurrence of epistaxis and telangiectases in relatives of these children. It was found there was no history of the occurrence of telangiectases in any of them, but their father, æt. 43, has bled occasionally from the nose all his life. He has three brothers, each of whom bleeds frequently from the nose, but his sister has never done so. The patient's father is the only one of his family who has had children. His wife died shortly after the birth of the last child. Nothing is known by the children's aunt of their mother or her relatives as regards their medical history. There are six children in the family: Michael and Mary, twins, æt. 15. The boy has frequently had epistaxis. Jane, æt. 14, has frequent epistaxis. Lizzie, æt. 12, has occasional epistaxis. The patients Maggie and John, twins, æt. 10. The girl has, since coming under observation, suffered from epistaxis; the boy frequently, during the last four years, since the nævi were noticed on his face. In none of these cases has bleeding occurred from anywhere except the nose, and all enjoy excellent health except John, who is described as "delicate" by his aunt, though no organic lesion can be found apart from those already mentioned.

Clinical Records.

ST. GEORGE'S HOSPITAL.

A Case of Chronic Nephritis treated by "Drainage and Feeding." (a)

By WILLIAM EWART, M.D., F.R.C.P.,

Senior Physician to St. George's Hospital and to the Belgrave Hospital for Children.

A. P., æt. 31, single, cook, temperate, and otherwise healthy, had suffered for twelve months from recurring attacks of renal œdema. No definite cause for the nephritis could be made out. When admitted to St. George's Hospital on August 3rd, 1901, there was moderate urinary output, 30 to 40 ozs., sp. gr. 1010, and albuminuria 1.45 per cent., with slight puffiness and anasarca. The pulse was rather tense, the breath heavy; there was debility, anorexia, malaise, and some headache. A milk diet and purgatives were prescribed with some general improvement; but no great change took place in the albuminuria. Towards the end of August, whilst still in bed, she had another unexplained nephritic attack, and the œdema of the legs became considerable. The "drainage and feeding treatment" being now available, both feet were incised on August 31st, and a liberal diet was allowed. The right leg was again incised, at the ankle, on December 5th, as the previous incision had ceased to run a few days before.

(a) Patient exhibited before the Medical Society of London on April 14th, 1902.

The usual improvement was obtained as regards general strength, appetite, and digestion. The albuminuria was lessened, but did not disappear. The pulse became softer, and the body weight and the complexion improved. Massage was subsequently added to the treatment, and she was allowed to walk about the ward, fluid still discharging from the incisions.

Importance attaches to the case in connection with the long persistence of the œdema, and the long duration of the drainage from the legs (from August 31st, 1901, to January 14th, 1902, a period of four and a-half months). During that time, whilst the kidney function remained inadequate, as clearly shown by the persistent œdema, the patient was steadily improving instead of degenerating, and it is not improbable that the nutrition of the kidney may also have improved. At any rate, she is much better instead of worse than six months ago, and better able to meet the strain of a fresh attack if it should occur. She is still able to take the same liberal mixed diet, and this is encouraging, my experience being that where little secreting substance remains, a generous diet quickly leads to uræmic symptoms after the vicarious relief of artificial drainage has ceased. At the present time the albuminuria persists (about 0.5 per cent.) and slight œdema also persists, fluctuating in its degree. She is now taking, in rotation, mercury with iron, arsenic with strychnine, and an alkaline stomachic with nux vomica. Under this treatment she is gaining strength, and she declares that she is feeling quite well, although it is obvious that the condition is one of improvement only, not of recovery.

The principles of this treatment were first published four years ago before the Royal Medical and Chirurgical Society (a), where they were somewhat adversely criticised. The patients submitted to it are, however, conscious of its value. Prior to its publication others, including Dr. Hale White (b), had advocated an abundant and mixed dietary. I believe that in bad cases this cannot be carried out without the protection afforded by drainage. Unfortunately, the benefits of this treatment are limited to those cases in which chronic nephritis is accompanied with anasarca.

Case of Peculiar Pigmentation of the Oral Surface of the Lower Lip. (c)

By H. D. ROLLESTON, M.D., F.R.C.P. Lond.,
Physician to St. George's Hospital, London, W.

THE patient, a man, æt. 40, was admitted under my care in St. George's Hospital with abdominal pain, constipation, and some tenderness over the right iliac fossa. When the lower lip was turned down vertical lines of black pigment were seen running in the same direction as, but superficial to, the blood vessels. Pressure on the pigmented streaks did not remove the discoloration, so although at first sight the appearance resembled that of varicose vessels, it cannot be explained in this simple manner. The pigmentation was best marked around some raised and somewhat enlarged buccal glands, and was strictly limited to that part of the lower lip opposed to the lower incisor teeth, which were loose, very foul, and coated with much tartar. At the margin of the receding gums of these teeth there was a blackish blue line resembling a "blue line"; my colleague, Mr. H. L. Albert, who kindly saw the patient with me was inclined to doubt whether it was a true blue line due to lead. In the upper lip which opposed a toothless maxilla there was no pigmentation. There was no pigmentation elsewhere in the mouth or palate, an abnormality seen in Lascars, and there was no reason to believe that the patient was the subject of Addison's disease.

Remarks as to the Nature of the Pigmentation.—The most plausible explanation seemed to be that the black

(c) A case shown at the Medical Society of London on April 14th, 1902.

pigmentation was due to sulphide of lead deposited in the mucous membrane, and that it was the outcome of the action of sulphuretted hydrogen, derived from the tartar on the adjacent incisor teeth, on lead carried by the capillaries to the mucous membrane. It may be mentioned that, according to Dr. T. Oliver (a), the black granules of sulphide of lead are in the deeper cells of the epidermis and not, as Fagge taught, in the small blood vessels. There was, however, no clear history of lead poisoning. The patient was a french polisher, and to his knowledge was not exposed to the action of lead, though he admitted to drinking beer at public-houses in the early morning. Moreover, he had never had wrist-drop, or gout, and though anæmic and subject to constipation and abdominal pain had no increased arterial tension or abnormality in his urine or heart. His urine was kindly examined chemically by Mr. F. T. Addyman, who reported that after most careful examination by various methods no trace of lead could be found.

It is difficult to exclude lead absolutely as a factor in this pigmentation, but at the same time it may, as was suggested at the meeting by Dr. Poynton, be due to mechanical infiltration with some extraneous body, such as Bismarck brown, which is used by French polishers in the ordinary course of their work.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

CLINICAL EVENING.

MEETING HELD FRIDAY, APRIL 25TH, 1902.

MR. HOWARD MARSH, F.R.C.S., President, in the Chair.

Left Parietal Meningocele or Cephalhydrocele.—MR. H. BARNARD showed a male infant, 2 weeks old, with a swelling on his head, which was noticed two days after birth, and had not increased in size. It was about the size and shape of half a small egg, and situated on the upper and posterior part of the left parietal bone, distinct from the anterior and posterior fontanelles and the sagittal suture. A bony edge can be felt around its site on the skull. It fluctuates, and becomes more tense on crying and coughing. An attempt to reduce it led to cessation of respiration and pallor.

Multiple Chondromata or Osteomata, with Synostosis of the Lower Epiphyses of both Ulnæ and Fibulæ.—MR. BARNARD also showed a lad who presented numerous tumours projecting from the ribs, scapulae, clavicles, and femora, &c. These are bony, hard, knob-like, and firmly fixed to the bones. The epiphyses are for the most part enlarged. The lower epiphysis of the ulna has undergone early synostosis on both sides, leading to ulnar displacement of the hand at the wrist-joint. The fibulæ are in the same condition. The internal malleolus is on the same level or a little lower than the external, and the foot is displaced outward as in talipes valgus. For this condition the patient has to wear irons. He suffered from severe rickets when an infant.

Tumour of Abdominal Wall.—MR. BARNARD showed another very interesting case—that of a woman, æt. 45, who had a large tumour of her abdominal wall of many years' standing. It had undergone no recent change. It is the size of a large orange, lobulated, very hard, uniform in consistency, and situated to the right of the umbilicus. When the patient raises her shoulders from the couch the tumour becomes partly fixed and more prominent. She had also an umbilical hernia.

Delayed Growth and Development.—MR. HASTINGS GILFORD showed a male dwarf, æt. 28, who came of a healthy and well-grown family. It was first noticed that he was not growing when he was between one and two years old. When first seen, just five years ago, he was three feet six inches in height, and has since grown about three-quarters of an inch. His height and proportions resemble those of a boy of between six and seven. A radiogram of the hand shows that the ossification is no farther advanced than is usual at the age of

ten, while the dentition is like that of a child of the same age, though the teeth are crowded and irregular. The contour of the body and the appearance of the head and face are all childish. But the sexual organs are the most backward in development, for the testes have not descended, and the external genitals are infantile. There is no hair on the body or face. The intelligence is good, but his behaviour and conversation are more like those of a child than of an adult. The voice is more treble than that of an adult, though it is not quite childish in tone and pitch. The thyroid gland can be felt. The imperfect development does not appear to be due to heart disease, syphilis, or defective action of the thyroid gland, or hypoplasia of the sexual organs. The condition is certainly not one of normal infantilism.

A Case of Ethmoidal Mucocoele.—MR. ANTHONY BOWLEY showed a man, æt. 28, who when five years old suffered from "an abscess in the left eye." This condition lasted for thirteen months, and was followed by a persistent swelling in the region of the upper part of the nose on the left side, remaining constant in size and free from pain. The swelling in the inner side of the right orbit he remembers to have had in its present state for the last ten to fifteen years, he has suffered no inconvenience from it whatever. On March 10th, 1902, he first noticed that he was unable to breathe through his left nostril, and at the same time he experienced pain at the inner side of his left eye, and noticed the swelling there to be increasing in size. Since then this swelling has progressively increased in size, become more tender, and accompanied by greater pain. He has never had headache, vomiting, or diplopia, and sees as well with one eye as the other.

Case of Congenital Absence of Nose and Anterior Nares, with Deficiency of Hard and Soft Palate.—DR. BECK WYNTER was represented by a female infant, 6 weeks old, the first child of healthy parents, who showed this very unusual deformity without "harelip" or deficiency of premaxilla. The child suffers from difficulty in feeding and respiration.

A Case of Probable Congenital Atelectasis.—SIR HUGH BENYON, Bart., showed a single woman, æt. 22, whose heart was on the right side, the apex or maximum impulse being in third axillary interspace. The right lung appears to have upper lobe almost solid, the bronchi not being patent, and the breath-sounds being almost absent. No previous illness from birth. A double coloboma of iris and developmental changes visible in lens and retina suggested that the case might be one of congenital atelectasis of lung or apneumotosis.

Excision of the Right Wrist for Tuberculous Disease by a Posterior Median Incision.—DR. W. G. SPENCER showed patient, æt. 26, who three years ago was suffering from tuberculous disease of the right wrist, which had already broken down, the wrist-joint, the carpus, and the tendon sheaths of the lower forearm being involved. Excision of the wrist-joint and carpus by a posterior median incision was done in April, 1899. In March, 1900, some sinuses in the right forearm were scraped, and arthrectomy of the left knee performed. Since then the patient has remained in good health.

A Case of Congenital Morbus Cordis, with Extreme Clubbing of Fingers and Toes.—DR. J. WALTER CARE showed a girl, æt. 10, who had always suffered from cyanosis and much dyspnoea on exertion, and feels the cold so much that she has only been able to attend school in the summer. There has never been any œdema. She is fairly well developed and well nourished, but shows a high degree of cyanosis, notably of the fingers, toes, cheeks, lips, and tongue. Clubbing of the finger-ends is excessively marked; the toes, especially the great toes, are also clubbed, though to a less extent than the fingers. The heart is considerably enlarged transversely, mainly to the right, but the exact nature of the lesion is obscure, as the only murmur heard is a very faint systolic one over the left border of the sternum, and most distinctly heard at the inner end of the second and third spaces. The heart intermits irregularly at times. The other organs appear to be normal.

Arthropathy in a Case of Pulmonary Tuberculosis.—

(a) T. Oliver, "Allbutt's System of Medicine," vol. ii., p. 972.

Dr. PERCY KIDD showed a man suffering from pulmonary tuberculosis who also exhibited swelling of both hands and feet, the enlargement affecting the fingers and toes, as well as the various joints. He states that he has had "gout."

A Case of Urticaria Pigmentosa.—Dr. BEVAN (introduced by Dr. Archibald Garrod) showed a child, the skin of whose trunk and limbs was covered with brown maculae, pinkish in some parts, which do not disappear on pressure. No irritation. Especially on the back, the spots become raised if the skin is rubbed briskly. No pigmentation of mucous membrane; no induration of skin; no blood change; no eosinophilia; no sign of visceral disease.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD AT THE ROYAL COLLEGE OF PHYSICIANS, ON FRIDAY, APRIL 18TH, 1902.

Dr. W. J. SMYLY, President of the Section, in the Chair.

BEFORE the business of the meeting commenced, Dr. PUREFOY, Master of the Rotunda Hospital, proposed a vote of condolence and sympathy with the family of the late Dr. Thomas More Madden, a foundation Fellow of the Academy, and for many years one of its most regular attendants. His contributions to the Obstetrical Section were numerous and valuable, and his pathological exhibits were among the most interesting. For some years past, ill-health prevented his attendance at their meetings, a distinct loss to their discussions. In his death, the Academy has lost one of its most accomplished and literary members, and an able and judicious obstetrician and gynaecologist.

Dr. GEORGE FOY having seconded the resolution, which was supported by Dr. W. J. SMYLY, it was passed in silence.

Dr. PUREFOY exhibited a large fibroid polypus uteri, and a uterus removed by pan-hysterectomy.

Dr. E. H. TWEEDY exhibited a large myoma removed by abdominal hysterectomy.

Dr. PUREFOY congratulated Dr. Tweedy on his successful operation; he would like to know if it would have been possible to excise the tumour from the uterus?

Dr. E. H. TWEEDY, in reply, stated that the tumour had no pedicle, but sat so down in the tissues of the broad ligament as to make either myectomy or enucleation impossible.

ROTUNDA HOSPITAL REPORT.

Dr. MACAN then opened the discussion on the Rotunda Hospital Report for 1901, and congratulated Dr. Purefoy on the satisfactory nature of the report, comparatively far more in the putting together of it than in the facts. There were some few points in the report which he thought called for observation. In Table III, he found that of 286 abortions it was thought necessary to curette 200. This is a very large proportion—two out of three cases. What were the indications that justified so many? To-day, the danger from plugging is almost nil, thanks to our antiseptic measures. Curetting is attended with danger in the puerperium; he has seen the principal assistant in the Munich clinic perforate the uterus at the very beginning of the operation. The application of the forceps in the extern maternity has the low proportion of 1 in 57.2 cases. Personal considerations enter so largely into the greater or less proportion of cases in which they should be used that we cannot say much on the question. But he cannot understand why it was necessary to have such a high proportion as one in 24.5 of the forceps for cases in the house, where the patient was throughout under observation, and the forceps could, if necessary, be applied at any moment considered advisable. In his own practice he now seldom applies the forceps, and he thinks the less they are used the better. Table V., cases of contracted pelvis, records the case of A. M., with an antero-posterior measurement of 7.5, who, unaided, gave birth to a living child, 8½ lbs. in weight. This case is remarkable, for the measurement is below

that which is considered necessary for the birth of a living child. Equally interesting is the case of M. H., whose child weighed 8½ lbs. In the treatment of accidental hæmorrhage he finds that the oxytocic properties of quinine are believed in; as for himself, he never found evidences of the alkaloid possessing such properties, and he thinks that five grains of it would not have much effect. He would, however, like to hear from Dr. Purefoy how the drug was used by him. The phrase inconsiderable bleeding as applied to *post-partum hæmorrhage* seems strange; he would not feel inclined to call an "inconsiderable" bleeding *post-partum hæmorrhage*. The frequency with which a red discharge is found to follow retroflexion of the uterus should be impressed on students. Too often it is thought that as the uterus is pressed down behind the pubis, there is a firm contraction, when the truth is that the uterus has become retroflexed and a red discharge follows. In the case of an anencephalic child exhibiting congenital luxation of both knee-joints, he regrets that Dr. Purefoy did not more fully describe the luxation, and he would like to get some particulars of the case. McClintock's case was characterised by the limbs flexing anteriorly at the knee-joint. The sub-division of forceps cases is not wholly satisfactory. In cases of episiotomy, he prefers the lateral incision, as if it does not give all the space necessary you can incise the opposite side; it gives better results than the mesial incision, and its after results are better. *Icterus neonatorum* is much more common than is generally supposed; fully 80 per cent. of children suffer from it, and as a rule they get well without any treatment at all. Withal, students should be told to be careful in their prognosis, for one of his cases died of it. He looks on the bad cases as due to malformation, and if for that reason alone they should not be too sure that every case will turn out well. He thinks that there is little use in setting up a morbidity table for yourself if with such a table you cannot make a comparison with other institutions; the report, however, showed extremely good results, in such cases a morbidity of 12 to 20 per cent. is considered a very good return. The case of Cæsarean section is rather obscurely reported. "Large fibroid lifted out of pelvis; pedicle transfixed and tied." Was it the pedicle of the tumour or of the uterus?—if of the latter the operation performed was that of Porro. To him, there is no evidence of any connection between the case of aphasia reported and the puerperal state. Lots of cases of aphasia occur, and they all get well; there is no necessary connection between the confinement and the recovery of the speech. If you can show a case in which during several consecutive pregnancies aphasia occurred and disappeared on the termination of labour in each case, it will be seen that some correlation exists, not otherwise. Of the case of pulmonary embolism we read: "Examination of the chest showed a patch of dulness at the base of the right lung, and the other signs of pneumonia." But we are not told when the examination was made—before she left the house or after her return.

Dr. JELLET congratulated Dr. Purefoy on his interesting report. There were just a few points left for criticism. He thought as he read it over that somebody had worked very hard at it for twenty four hours in collecting a great mass of materials, and then had neglected to spend a couple of hours in putting them into shape. At the very beginning, he finds that the mortality table was forgotten; while in the section on accidental hæmorrhage it is recorded that two mothers died, but there are no particulars given of them in the list of interesting cases. In the case of rupture of the uterus and vagina he considered that the accident was due to the plugging, the tampon being allowed to remain after the uterine contraction had commenced. He considered that the tampon should be removed when the uterine pains are well begun. Quite recently a student of the Rotunda told him that the plug was allowed to remain in position until expelled with the child. The measurements as given in the table "contracted pelvis" appear to show that they get round pelvis in the Rotunda, and he cannot help thinking

that the measurements must be wrongly taken. Menstruation appears to him to be a misnomer for the red discharge that occurs in newly-born female children. It is an isolated hæmorrhage, not a menstrual flow. He congratulated Dr. Purefoy on a mortality equal to any since the hospital was founded.

The PRESIDENT (Dr. Wm. J. Smyly) congratulated Dr. Purefoy on his excellent report and the very low mortality of three out of 1,600 cases. He does not approve of curetting after abortions—it is not good practice. But a good deal depends on the kind of curette used: sharp, semi-sharp, dull. In all abortion cases where curetting is called for, he uses the dull instrument. The uterus during the puerperium is abnormally soft, especially its mucous lining; if you curette it all thoroughly there is the risk of perforating the wall, and if you curette imperfectly you leave septic matter close to a raw surface, a nidus of infection. In no case should a sharp curette be used. He recommends postponing the operation for six weeks. At the end of that time, the risks attendant on the operation are considerably lessened and you then can recognise the firm muscle tissue under the instrument as you use it. In reference to the use of the forceps we read that the indications for their use are (1) danger to the mother, (2) danger to the child. But how are you to tell? They sometimes have to be used to save the mother unnecessary pain. He cannot see that all the women on whom they were used in the house were in danger. He, however, thinks that we differ more in expression concerning them than in practice. The taking of the pelvic measurements is not always easy of performance. Skutsch's pelvimeter, which he prefers, is an awkward instrument and very inconvenient to use. He would like to learn from Dr. Purefoy something more of his case of transverse narrowing at the outlet, which is a condition of great interest. In cases of narrowing of the pelvis, he was formerly inclined to practice version, but latterly he allows the head to mould; he would like to hear what the present teaching is. Thirty-seven cases of accidental hæmorrhages seems an extraordinary number for one year; they formerly looked on concealed hæmorrhage as almost fatal; here it seems to signify little. He looks on the plug as dangerous if left in the vagina long after labour has commenced. But he cannot agree that in the reported case the plug occasioned the tear. The injury may have been due to one of three things: (1) plugging the vagina; (2) pressure of the head on the cervix; (3) pulling up of the vagina. *Ophthalmia neonatorum* was one of the troubles he prided himself, while Master of the Rotunda, on keeping the house clear of, and yet in that section on one occasion when some ophthalmic surgeons were present he heard that their hospital clinics were crowded with cases of the disease in children who came from the Rotunda Hospital.

Dr. PUREFOY begged to thank the members of the Section for the reception they had given his report, and particularly those who pointed out its defects. Dr. Macan had waxed eloquent on the unwisdom of curetting, but he did not agree with him at all. He had had a very large experience both in the Coombe and in the Rotunda, and he was of opinion that the sooner you curetted and removed all septic matter from the womb the better. Of the wisdom of this procedure, he was quite satisfied. The dangers of the operation were known to all. As to the question, Should it be necessary to curette two out of every three cases? He would answer: Curetting is expedient, even if not necessary. He did not mention that he used a blunt curette, for he took it for granted that the members were too familiar with the fact that a sharp curette should not be used in a parturient womb. Forceps were used under the indications plainly pointed out; they acted on the nature of the case and the condition of the patient. The state of the patient, not the length of time, regulated their conduct. Pelvic measurements were carefully taken and accurately noted, but all who take such measurements must be conscious of the difficulties of such work. The transverse narrowing of the outlet was due to approximation of the tubera ischii; he regrets that the patient was

allowed to leave before measurements were taken. The oxytocic properties of quinine are known and advantage taken of them to stimulate uterine action. He finds five-grain doses of the alkaloid every four or six hours an excellent oxytocic remedy. *Post-partum* hæmorrhage is a relative quantity; it may be severe or slight, and a small discharge is quite as much entitled to the designation *post-partum* as the most profuse. The lateral and bilateral incisions in episiotomy advocated by Dr. Macan are not at all equal to the mesial incision he practises and recommends; the single lateral incision does not give as much space and the bilateral incurs the risk of gangrene. Dr. Macan takes exception to his morbidity tables. When he became Master in the Rotunda he found them as they had been drawn up by Dr. Smyly; he liked them and adopted them, and he had heard nothing that would cause him to change his opinions. As for his case of aphasia and of its connection with the puerperal condition, he commends it to Dr. Macan's leisurely study; that he (Dr. Macan) should ask unequivocal proof is natural. He recently saw his patient, and he is happy to say she is quite well, speaking quite freely. The lungs of his embolic patient were not examined immediately on her readmission; the woman was in a state of collapse, but they were examined within forty hours of the time, and he might add that there was an early pyrexial stage in the case. Dr. Macan was not satisfied with the success of their prophylactic treatment of *ophthalmia neonatorum*, although they had only four cases out of more than 1,600 children. All he could say was that Dr. Macan is hard to please. They used from one to three drops of a 2 per cent. solution of nitrate of silver. Dr. Jellett stated that the table of mortality was forgotten, but there was no forgetfulness in the matter at all. Three patients died during the year, and on the sixth line of the report they are recorded. Of the two cases he cannot find in the "interesting cases," one is told with the necessary fulness in Table III. and the other is included in the "interesting cases." He had already stated that pelvic measurements are very carefully taken. His teaching as to the plug is that when strong pains begin it is to be removed; there are, however, multipara whose pains expel the plug before its protrusion has attracted attention. As for the objection to the term menstruation, it is futile; for all he (Dr. Purefoy) knows the child may have menstruated at the next monthly period. The question of version or allowing the head to be moulded to the passage is decided in every case by its circumstances. If the head is in a favourable position and the patient in good state the case is allowed to proceed; otherwise version is performed.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT MANCHESTER APRIL 18TH, 1902.

Dr. S. BUCKLEY, President, in the Chair.

SPECIMENS.

Dr. WM. WALTER (Manchester) showed a specimen of "Adenoma of the Uterus" treated by vaginal hysterectomy. There had been almost continuous uterine hæmorrhage for three months in a single patient, æt. 39. Curetting had failed to arrest it. He performed anterior colpotomy and incised the front wall of the uterus sufficiently to explore the condition of the endometrium. Finding a villous growth attached to the fundus, the uterus was removed. The after history was uneventful. Histologically the growth proved to be an adenoma.

Dr. ARCHIBALD DONALD (Manchester) showed a "Uterus Extirpated per Vaginam" from a widow, æt. 47, for recurrent polypi. There had been metrorrhagia. Numerous polypi were found originating from the cervical wall. They were freely removed by scissors and scraping. Four months afterwards the polypi had returned, but were more numerous and larger, almost filling the upper third of the vagina. Owing to the rapid recurrence the case was looked upon as clinically malignant, and hysterectomy was therefore done.

The patient made a good recovery. On opening the uterus several polypi were found in the true uterine cavity. On microscopical examination of the growths in no part was there any appearance of malignancy. The uterine wall was not involved in the growth.

Dr. E. O. CROFT (Leeds) showed a "Placenta Duplex" from a single gestation. The specimen was obtained from a case of albuminuria with eclampsia at full term. The placental tissue was divided into two equal portions united by a thin membranous band about two inches wide. The cord entered the centre of this membrane, and its vessels then spread out into two groups to the placental portions. The fœtus was small and stillborn.

EXTIRPATION OF THE UTERUS FOR CANCER OF CERVIX.

Dr. W. J. SINCLAIR (Manchester) described a case in which he had extirpated the uterus for cancer of the cervix by the para-vaginal (Schuchardt's) operation. The patient was a married woman, æt. 46. The disease was somewhat advanced, and was on the boundary line between radical and palliative treatment. There was some induration of the parametrium on the left side. The bladder was free and could be separated. By the method adopted a larger accessibility to the disease is obtained by widely opening up the ischio-rectal fossa and so reaching the parametric tissues. Dr. Sinclair was able to see the left ureter and to remove some growth which was beneath it. The ovaries and tubes were removed with the uterus. A few stitches were placed in the peritoneal flaps to prevent prolapse of the bowel, and the vagina loosely packed. Dr. Sinclair thought a tight packing of the vagina in vaginal hysterectomy was harmful and sometimes caused sloughing perforation of the bladder. He considered that in a case where radical operation was justifiable the paravaginal method was most satisfactory and he did not approve of extensive abdominal operations for cancer of the cervix.

Dr. J. E. GEMMELL (Liverpool) related two cases of double

SOLID OVARIAN TUMOURS.

(1) A nullipara, æt. 45, had been said to have an ovarian tumour seven years previously, but it was not treated. For twelve months she had severe abdominal pain, much gastric disturbance, and floodings. There was much ascites; the liver was enlarged. An irregular solid mass was felt in the lower abdomen. A fibroid nodule was also felt in the posterior uterine wall. Owing to a history of excessive indulgence in spirits and to the condition of the liver, the ascites was thought to be possibly cirrhotic, but the long existence of an ovarian tumour also suggested the possibility of fibroma or malignant tumour of the ovary. The presence of the fibroid nodule and the metrorrhagia caused further difficulty in diagnosis. The gastric trouble was relieved and the abdomen opened. Much blood-stained fluid escaped and two ovarian tumours removed; the small uterine fibroid was also enucleated. The ovarian tumours were mainly solid, but contained some cystic portions. The growths were carcinomatous. Malignant deposits were seen on the intestines, omentum, and liver. The patient was much relieved of her symptoms, but died about three months later.

(2) A married woman suffered from pelvic pain and much dyspepsia, which did not yield to medical treatment. The menses had become more frequent and profuse. A solid ovarian tumour was diagnosed. On opening the abdomen some clear ascitic fluid escaped, and a large solid ovarian tumour was removed from the right side, and a smaller growth of similar nature from the left side. The larger growth presented a cyst about the size of an orange at one part. The microscopical sections which were exhibited showed the growths to be true fibroma.

Dr. W. WALTER said that when the abdomen was explored and secondary malignant growths discovered, it was a question whether the primary growth should be removed. Such cases bear operation badly. When, as in Dr. Gemmell's first case, the tumour is partly cystic and can be removed with reasonable safety, it is

better to do so. The cystic portions if left are liable to perforate speedily and lead to peritonitis.

Dr. LLOYD ROBERTS described a case of

DEATH FROM URÆMIA AFTER OVARIOTOMY.

A patient, æt. 58, multipara, was found to have a large ovarian tumour extending to about three inches above the umbilicus. There was a considerable cloud of albumin in the urine. The patient was kept under treatment by diet and medicine until the urine contained a mere trace of albumin. Abdominal section was performed and an ordinary multilocular ovarian tumour of the left side removed. After operation the quantity of urine decreased and the albumin increased again. The patient became restless and sleepless, and vomited frequently. Death from uræmic coma took place on the tenth day, only eight ounces of urine loaded with albumin having been passed during the last forty-eight hours of life. There were no signs of septicæmia or peritonitis. Post-mortem, double nephritis was found, the other organs being healthy. The case demonstrates the gravity of the risk in performing major operations in cases of renal degeneration.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, April 26th, 1902.

STRICTURE OF THE COLON.

At the meeting of the Société de Chirurgie, M. Terrie communicated an interesting case of stricture of the colon in a woman of forty. At the left angle of the transverse colon a tumour was felt, while that portion of the intestine appeared dilated; the patient seemed to suffer greatly at times. Believing in the existence of an obstacle due to the presence of a neo-plasm at the left angle of the colon, M. Terrie performed laparotomy. When the abdomen was opened he remarked that the descending colon was much smaller in calibre than in the normal condition. On the other hand, the transverse portion was drawn down so that the left angle of the intestine was absolutely acute, forming a kind of fold. There was no neo-plasm. The operator established a communication between the transverse and the descending colon, and the patient made a good recovery.

ANEURYSM AND GELATINE.

M. Reynier related a case of arterio-venous aneurysm of the cavernous sinus treated successfully by injections of gelatine. A woman of 41 fell heavily on her head a year ago, sustaining a fracture of the base of the skull. Soon afterwards all the signs of aneurysm of the cavernous sinus appeared. The speaker ligatured the right carotid artery two months after the accident; the operation seemed to have at first a good effect, but soon the bruit de souffle reappeared, and at the same time cerebral troubles due to the ligature of the carotid artery set in. M. Reynier had thought of placing another ligature on the left carotid, but hesitated before the gravity of the operation. As a *pis aller* he advised the medical attendant to inject morning and evening gelatinised serum. By degrees the aneurysmal souffle diminished under the treatment, and ultimately disappeared. The woman has since enjoyed perfect health.

HÆMOPTYSIS.

Another surgeon said that injections of sterilised gelatine solution succeeded with him in cases of obstinate hæmoptysis occurring in consumptive patients, and where the usual remedies, such as ice, opium, hippo, ergotine, failed. He injected a drachm of a 5 per cent.

solution morning and evening in the gluteal region. On the second or third day the hæmorrhage ceased.

TREATMENT OF RICKETS.

Dr. Carrière spoke on the treatment of rickets by cod liver oil, to which he added lecithine. For the past year he had treated in this manner five children under two years of age, for whom he ordered each day from one to four tablespoonfuls of cod liver oil, containing one grain of lecithine to the tablespoon. Each of the five children was completely cured in a period varying from four to six months.

LOCAL TUBERCULOSIS.

Dr. Bue publishes several cases of tuberculous ganglions cured by injections of chloride of gold. He says that chloride of gold, which had hitherto been employed in various affections, had for a long time fallen into undeserved oblivion, as it possessed advantages equal to iodine. M. Bue used it as injection in cases of non-suppurating glands and in cold abscesses. The solution he uses is composed of chloride of gold and chloride of sodium, of each one gram, water fifty grams. He injects from five to ten drops every eight days into the non-suppurative ganglions. After a few weeks the glands wither up and finally become absorbed, without leaving any trace of a cicatrix. Where the ganglion is in process of suppuration he removes the abscess and fills the cavity with a small plug of antiseptic cotton steeped in the chloride solution.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, April 26th, 1902.

At the Society of Psychiatry Hr. Jolley reported on three cases of

TRAUMATIC DISEASE OF THE SPINE.

The level of the disease was different in all three cases. Two of the cases were shown as improved, the third died. The first case was one of spastic paresis of the lower extremities. The patient could only move forward when led. Nine months ago he was kicked by a horse on the neck; he did not lose consciousness, but was at once unable to walk. Soon there was paralysis of the lower extremities with pronounced gibbosity in the neck, the prominence being formed by the first and second dorsal vertebrae. When admitted into hospital there was flaccid paralysis of both legs and absence of patellar reflex; these returned in the course of two months, and then a condition of spastic paralysis developed. Movements of the legs were best in the morning. There were strong cutaneous reflexes, which led to frequent passing of urine; above the dorsal segment everything was intact. There was probably fracture of the vertebrae with displacement of the parts. There was also probably hæmorrhage compressing the anterior parts. The symptoms had gradually improved, and still further improvement was not impossible.

The second patient showed flaccid paralysis of the lower extremities. The injury was in the lowest part of the vertebral column. The patient fell from a scaffolding a distance of eighteen to twenty feet, a year and a-half ago. He fell on the feet, doubled up, and struck on the sacrum and ischia. In trying to save himself with the left arm, the forearm was broken. He did not lose consciousness, but could not walk. Three days

after admission the flaccid paralysis was noted, and he had a mild attack of delirium tremens.

On lumbar puncture bloody fluid with degenerated blood corpuscles was drawn off. Hæmorrhage had therefore taken place into the spinal column. Voluntary movement both in toes and the thighs was still present, but ceased during a second attack of delirium with pneumonia. Sensibility was retained. There was also incontinence of urine and faeces, but this passed off as the delirium got better. There was also a rather sharp cystitis which also improved. The first spontaneous movements of the upper parts of the legs began three months afterwards. The patellar reflexes had not yet returned, and the legs still had but little power. The left leg was more affected than the right. No doubt alcohol had helped to make matters worse, but comparative recovery might still take place.

The third case was that of a mason who fell on to his back from a third story. He lost consciousness, and on awakening had complete paralysis of the lower extremities. The injury affected the fifth to eighth segments of the dorsal vertebrae. Complete flaccid paralysis, with absence of patellar reflex, paralysis of bladder and bowel. Loss of sensibility to pressure, pain, touch, temperature up to the sixth ribs, and priapism. After improvement in the local symptoms there was distinct gibbosity. The paralysis continued, but the reflexes returned. Cystitis and pyelitis came on, and the patient died with symptoms of uræmia. At the autopsy no displacement of vertebrae was found, but the intra-vertebral cartilage between the sixth and seventh vertebrae was very thin and fibrous.

Hr. Henneberg reported two cases of

SPINAL SYPHILIS.

In the first case there were meningitis, neuritis, and gummata with secondary degeneration of the posterior columns. The patient denied syphilitic infection. The symptoms first appearing with headache after a fall four months before admission.

Condition on admission: Very imperfect pupillary reaction, optic neuritis and paresis of the left abducens, imperfect hearing on the left side, uncertain gait, exaggerated patellar reflex, no disturbance of sensibility, dementia.

Course during the first months: Frequent vomiting, then complete blindness and deafness, epileptiform attacks. Death in two and a-half years. There was marked gummatous infiltration of the arachnoid and of the posterior dorsal roots, these being seen to be thickened by the naked eye.

The second case was one of meningo-myelitis of the cervical cord; initial tabes. The patient was a woman, æt. 32, admitted in 1898. She had never before had any serious illness. She was infected by her husband seven years ago. The sores healed after inunction treatment. For a year she had had formication and numbness in the hands and pain in the neck, increasing paresis of the arms and legs, latterly frequent vomiting; no anti-syphilitic treatment. On admission: Pupils unequal. No reaction to light in the right; in the left, slight. Fundus normal; cerebral nerves intact; movements and pressure on the cervical spine painful; paresis of arms and legs; no atrophies or changes on electrical stimulation. Reflexes of arms and legs retained; no exaggeration; no ankle clonus. Slight

lowering of sensibility on the arms and thorax. Death suddenly, a week after admission. Autopsy: Chronic leptomeningitis fibrosa on convexity and base. Meningomyelitis of the upper and mid-spinal cord. No great vascular changes. In the upper dorsal cord intramedullary degeneration of the posterior roots. In the lumbar cord slight degeneration of the mid-root zone. In the case described, along with the meningitis was a commencing true tabes. Both affections were co-ordinated, and obviously of syphilitic origin.

PATHOLOGICAL CHANGES IN NUTRITION.

At the last meeting of the "Gesellschaft der Aerzte" Freund engaged the attention of the members on the subject of medical or physiological chemistry of the fats and carbo-hydrates. Beyond the amounts taken in and eliminated very little had been added, he said, to our knowledge on this subject, although the albuminates had been well discussed and followed in the course of assimilation and transformation in the different organs, with the net results of ingress and egress. These are not unfrequently fallacious, as in the case of gout, where one would expect the uric acid to be suppressed or lowered, and not equally balanced as is usually the case; in many cases increased. In leucocythemia the uric acid is greatly increased without any formation of calculi, as there is sufficient alkali present to keep the acid in solution.

In diabetes it is the reduction of the power of the hepatic cell and not a chemical change, which is but a physical alteration, that causes the absorption of the glycogen.

To accomplish this nutrient transformation of the hepatic secretion the pancreatic action is an absolute necessity, since it prevents the glycogen entering the hepatic vein to be eliminated by the kidneys. To prove the fallacy of the clinical analysis being relied on we have very good examples of the hepatic cells being found perfectly healthy, as in the foregoing case, and when the cells are found altered and degenerated the products are found to be healthy and in normal quantity. From a closer examination of diabetes we may conclude that the presence of sugar in the urine is due to an abnormal dilatation of the hepatic capillaries, by which a quantity of the glycogen escapes and is eliminated. This dilatation may be artificially produced through the nervous system as by "pique," or by poison, as in the case of phloridzin.

Fevers cannot be explained by chemical analysis any more than uræmia or diabetes. Peptone, when injected into the blood, will produce fever, although the cells and contents of the bowel are at all times loaded with peptones without there being any fever. From this we may conclude that this substance *per se* does not cause the fever, but that it is present in the wrong place.

A careful consideration of the whole facts connected with obesity and lithiasis convince us the raw material cannot be put into the machine as a manufacturer does, and extracted minus so much water and waste.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

CHOLECYSTENTEROSTOMY.—Mr. BATTLE operated on a patient, a labourer, æt. about 60, who had been sent to the hospital suffering from obstructive jaundice. He was a big, stoutly-built man, with a deeply jaundiced appearance, conjunctivæ being a deep yellow, whilst the dilated capillaries in his cheeks gave him the appearance of what is known as black jaundice. He gave a history of eighteen months to two years' duration of attacks of pain of varying intensity, which took him in the region of the gall-bladder, and were accompanied with vomiting. They had got more severe of recent months, though not numerous at any time. Jaundice had appeared gradually about two months before and had increased somewhat rapidly, and during that time he had had more or less continuous pain in the region of the gall-bladder; he had not lost flesh. Examination of the hepatic region showed a rounded tender swelling, which descended on inspiration, situated in the position of the gall-bladder. The liver was also enlarged and firm. Nothing abnormal could be discovered in any other part. It was suggested that the obstruction to the common bile duct might be due to the pressure of a gumma, and the patient was placed on iodide of potassium for a fortnight, but no improvement followed, and during the last week he complained of increased pain in the gall-bladder, and that organ could be felt larger from day to day. Accordingly exploration was carried out through a perpendicular incision which divided the right rectus; this was necessarily a long one, as the patient was so fat. Examination of the ducts and head of the pancreas showed a definite thickening about the latter part, but nothing in the nature of calculus. Not far from the tumour in the pancreas some enlarged glands could be felt. As this was evidently a condition which could not be removed, it was decided to make a communication between the gall-bladder and intestine, so as to bring the bile into the bowel by another route. A convenient portion of intestine (jejunum) was selected and emptied with pressure; the gall-bladder was emptied and brought into apposition with the loop of bowel; a continuous stitch was then passed, after Lembert's method, so as to form a curved line of junction between the two. An incision about an inch and a half long was made above this into both intestine and gall-bladder, and the openings so made adjusted one to the other by means of a continuous stitch which united the edges in their full thickness all round. The part was washed with saline solution, and the first continuous stitch carried round the front, uniting the two structures together about a quarter of an inch from the opening. By this means two circles of suturing were completed. The opening through which the gall-bladder had been emptied was sutured, the packing removed, and the parts returned to the abdominal cavity, the wound in the abdominal wall being afterwards sutured in layers. Mr. Battle said that he had been rather in favour of the view that the obstructing cause in this case was a gall-stone in the common duct, and he had come to this conclusion because the history was a long one and the patient showed none of those signs which the surgeon is accustomed to associate with the presence of malignant

disease in the abdomen. The gall-bladder itself was not much hypertrophied, and this condition pointed rather to the presence of a growth than to the probable presence of a gall-stone, and enlargement of glands also pointed to malignant disease. The patient was intensely jaundiced, and the dangers of an acute cholemia developing after operation had to be faced as well as the likelihood of unusual bleeding during the operation, but it was not possible to avoid operation. Chloride of calcium was given for a couple of days beforehand, and it was possible, he thought, that this prevented undue loss of blood, as there was nothing remarkable in that respect.

Since the operation the jaundice has gradually got less marked and the patient's condition is much better; he has lost all pain, and expresses himself as much relieved.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 54d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d., Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 30, 1902.

THE PURE BEER BILL.

THE second reading of the so-called Pure Beer Bill was last week rejected by a large majority of the House of Commons. Its very title seems opposed to the instincts of sound legislation, inasmuch as it begs the question of purity. The avowed aim of the proposed measure, as set forth by the member who moved the second reading, was to make it compulsory for brewers to brew their beer from barley malt, coupled with such an amount of other ingredients as was necessary to make the article saleable and suitable for consumption. The Bill provided that eighty-five per cent. of the total saccharine yielding materials was to be malt, that there should be no substitute for hops, and that means should be taken to make it known whether or not the consumer was drinking home-made or imported beer. To impose conditions of that kind upon the brewers, it is urged, would be to sound the death-knell of scientific brewing in the United Kingdom. The term "beer" is somewhat wide

and general, and applies to an alcoholic product of sugar fermentation that may vary widely in quality and flavour, and yet still fall within the original definition. The difference between mild lager and old strong ale is almost as great as that between wine and brandy. It would not be difficult to accept the position of the promoters of the defeated measure were it possible to show that the consumers of sugar-brewed beer were injured in health or defrauded in pocket by the use of substitutes for malt and hops. Beer is beer, and the majority of consumers, apart from flavour, would have to call in the aid of an analytical chemist to say from what materials the beverage was made. The objections are not on that account to be dismissed as merely sentimental, because flavour in a beverage is almost as important an element as its slaking quality; indeed, it is the flavour one pays for in certain highly-rated French wines. If he were to go back to Anglo-Saxon and Norman times, however, he would find that ale, or a very analogous beverage, was brewed from honey and a variety of things other than barley, while the hop is a comparatively modern ingredient of beer. The fact of the matter seems to be that the Pure Beer Bill is to a great extent a political measure based on a popular sentiment. Mr. Chaplin wants us to go back to barley, whereas modern science has shown us how to make chemically similar beer from barley substitutes. In other words, he asks consumers to reject the products of latter-day scientific research in spite of the fact that the latter are not more detrimental to health than the malt and hop article. The needlessness of the proposed change is proved by the fact that the Bill proposed to allow brewers to put fifteen per cent. of ingredients other than barley into their beer. If fifteen per cent. be permissible in beer that is now consumed daily, why should not thirty or forty or fifty be allowed? In seeking to reduce to legislative form the fallacy that beer produced from malt and hops is the best, the promoters of the Bill have overlooked the fact that the brewers would very possibly buy foreign barley, so that the farmers of the United Kingdom would not be better off than ever in this respect. The chief impetus of the "pure beer" movement undoubtedly lies in the great outburst of arsenical beer-poisoning in Manchester a couple of years ago, but the machinery which detected and ultimately arrested that epidemic will detect and prevent other similar unfortunate occurrences with much greater certainty in the future. There is not a single additional safeguard in Mr. Chaplin's Bill, which seems to be indefensible upon the lines of political economy. The whole question was ably summed up in the Commons by Mr. Fletcher Moulton, the lawyer and man of science, who pointed out that in these days, when our industrial supremacy is alleged to be endangered by want of technical instruction, it was proposed by this pure beer measure to abandon the advantages which science had provided us with in one great industry. Science has enabled brewers to produce with absolute certainty of result a

wholesome beverage, which was quite unattainable by the old processes, and the proposed measure would compel the brewers to return to old and obsolete methods. In this case the common sense of the House has vindicated the claims of science. There can be no doubt that the more general adoption of the lighter sugar-brewed lager beer would advance the cause of temperance among our countrymen.

LEUCOCYTIC COUNTS IN THE DIAGNOSIS OF INTERNAL SUPPURATION.

AMONG the methods of diagnosis which recent research has placed at the disposal of the physician and surgeon that afforded by the routine examination of the blood is certainly the most important. The variations in number and appearance which the figured elements of the blood undergo as the result of disease, and more particularly the modifications in size, number and general characteristics of the white corpuscles, have been shown to be intimately associated with certain morbid states, the existence whereof may thus be inferred. It is in virtue of these observations that, quite recently, eosinophilia on the one hand, and polynuclear leucocytosis on the other, have been prerecognized as evidence of appendicitis. The principal point to be borne in mind, however, is that even if we do no more than enumerate the corpuscles, information of the greatest value is afforded in connection with inflammatory conditions associated or not with localised suppuration. Professor Curschmann, of the School of Medicine of Leipzig, who, during the last three years has attentively studied this phase of diagnosis, asserts that the mere enumeration of the white corpuscles affords constant and trustworthy evidence of the existence of suppuration. His conclusions are based on the close observation of sixty patients suffering from appendicitis, and he found that, while in simple non-suppurative appendicitis the proportion of white corpuscles remains unaltered, or at most undergoes a slight increase at the onset, promptly returning to normal, when pus is present their number increases in a marked degree, and remains persistently above normal. The only other morbid state in which any such increase takes place suddenly is in diseases such as pneumonia, which are also associated with abnormally active leucocytosis. The usual proportion of white corpuscles is from 8,000 to 10,000 per cubic millimetre, and if we find, even on a first examination, that the proportion exceeds 25,000, we are justified in suspecting suppuration. Later on in the course of the disease this excess is pathognomonic, and constitutes a sufficient justification for surgical intervention. Further, he noted that when the abscess has been opened and drained the excess of white corpuscles soon falls to normal, and should this reduction not take place there is *ipso facto* reason to suspect the existence of, as yet, unopened foci. The same reduction takes place when a perityphlitic abscess discharges spontaneously, either externally or into one or other of the hollow viscera. According

to this observer, this method of diagnosing suppuration is much more trustworthy than that based on the observation of the temperature, indeed it is notorious that the temperature not uncommonly fails to afford any intimation of the existence of even wide-spread intra-peritoneal suppuration. The phenomenon of leucocytosis is absolutely constant, whereas the indications of the thermometer are subject to a wide margin of error. A further point, which has been elucidated by Professor Kuttner, of Tübingen, is that when, after operation, the leucocytosis persists, we should suspect septic mischief, while, if the proportion of leucocytes diminishes, this complication may be discarded in spite of the persistence of fever. The method has been applied to the diagnosis of suppuration in gynaecological practice by Dr. Dutzmann, of Greifswald. He examined the blood of forty patients suffering from various gynaecological affections, always taking care to make the examination at the same hour of day in order to avoid the disturbing influence of the physiological variation in the number of leucocytes. He found—and his findings were in every case confirmed by operation—that hyperleucocytosis was in many instances the sole indication of suppuration, and in contradiction with the other symptoms, yet it proved to be trustworthy. He found this method of the greatest service in distinguishing uterine cancer from suppuration, uterine fibroid from pyosalpingitis, and so on. On the other hand, in cases in which the diagnosis of suppurative salpingitis was arrived at in the absence of hyperleucocytosis, operation failed to demonstrate the existence of pus. With such facts as these before us it is to be hoped that advantage will be taken of the method in all obscure cases; indeed, the value of the method has now been sufficiently demonstrated to justify its being practised as a matter of routine, not only in hospital wards, but in general practice.

GOITRE.

THE much bewritten subject of goitre has again been brought into prominent evidence before one of the scientific societies of the French metropolis by M. Lucien. He has, of course, dished up the time-worn information that it is more common in the mountainous regions of France than in the approximately plane districts, and pointed out that the same general rule holds for Switzerland, Germany, and Italy. But he also lays great stress on the less well-known fact that the growth and distribution of cretinism are by no means coterminous with those of the goitrous condition, with which most of us have been accustomed to—inseparably—associate it. The causes of cretinism, according to M. Lucien, are not identical—even approximately—with those of goitre; and, having regard to this fact, we must re-examine their distribution and their frequent coincidence in a new light of inquiry. Whether the novel element of illumination will lead us much nearer to the final goal of knowledge of these decidedly mysterious conditions is a question

of the future. The subject of *gottre* recalls to the memory of those of our readers who have wandered with mental profit into the wide fields of general literature two of the most interesting personalities in the history of British poetry—Oliver Goldsmith and Thomas Gray. The former—the erratic, ill-disciplined Roscommon youth—the patientless graduate in medicine of the Dublin University, when on his ragged, half-barefoot, flute-playing tour through the Continent of Europe, noted that in some of the Swiss districts, when a young woman approached the marriageable age, she was obliged—in the rare cases in which Nature's usual process had failed to supply her with the recognised proportion of thyroid development—to wear a *false goitre* in order to give herself a chance of the usual settlement in life. The author of the "Elegy written in a Country Churchyard" wrote home to his friend, Mr. West, from Turin, on November 16th, 1739, describing his experiences and impressions of crossing Mont Cenis. At this date, so far preceding the conception and construction of the present railway tunnel, Mr. Gray found reason to complain that "Mont Cenis carries the permission that mountains have of being frightful, rather too far; and its horrors were accompanied with too much danger to give one time to reflect upon their beauties." He also informs his correspondent that "the creatures that inhabit them [the Alps of the neighbourhood] are in all respects below humanity; and most of them, especially women, have the *tumidum guttur*, which they call *goscia*." Of Mont Cenis he further tells us that "there is a family of the Alpine monsters I have mentioned upon its very top, that in the middle of summer calmly lay in their stock of provisions and firing, and so are buried in their hut for a month or two under the snow." From such observations it would appear that the holiday medical tourist of the present day who avails himself of the rapid and comfortable transit supplied by the great Mont Cenis tunnel, loses like an opportunity of observing the appalling grandeur of some of Nature's most impressive architecture, and of examining the most striking specimens of one of Nature's most mysterious pathological aberrations.

Notes on Current Topics.

An Indictment against Tobacco.

THE very latest that we have heard of the anti-social influences of *tobacco* is that the cigarette has been brought up in scientific custody, charged by Dr. Le Juge de Segrain, of Luchon, with the infliction upon its over-confiding devotees, of the physiological mutilation of impotence. The prosecution has been opened in the current number of the *Archives Générales de Médecine*, and the charge has been further maintained by the corroborative testimony of Dr. Georges Petit, who conducted experiments on a number of conspicuously philoprogenitive animals, dogs, cocks, rabbits, and guinea-pigs, by the various methods of inhalation (of smoke) of gastric

injections, and of rectal enemata. Sclerotic changes were thus induced in the testes—and ovaries—of the animals subjected to experiment. Coming from the land of dwindling population and decreasing families, such information possesses special value. It is interesting to note in this connection that in the quaint and rare work of the French explorer, André Thevet, who went, in 1555, to America with the object of taking part in the foundation of a French colony near the mouth of the Rio Janeiro, there is special mention made of the anti-aphrodisiac properties of tobacco. In "*Les Singularités de la France Antartique, autrement nommé Amérique, et de plusieurs Terres et Isles découvertes de nostre temps*," a quarto dear to the heart of the bibliomaniac, and bearing date 1558, this observant traveller tells us that "the women in America forbore the taking of Tobacco, because that they have been taught that it will hinder conception and bodily lust" [Parkinson's paraphrase]. What physiologist, even in the twentieth century, can be sure that he has made an absolutely original discovery!!

Atmospheric Cleansing by Snowfall.

SNOW, and probably rain, rank high among Nature's methods for the purification of the atmosphere. The air of cities is rich in germs, a certain proportion of which are pathogenic, and apart from microbes the atmosphere is more or less heavily laden with minute organic particles which irritate and otherwise damage the respiratory tract. Some experiments recently carried out by the Chicago Board of Health illustrate this cleansing action very well. Culture plates exposed on January 18th gave colonies varying in number from 630 to 1,050. On the 21st snow fell to the extent of 0.28 of an inch, and the experiment was repeated on the 22nd, when the number of colonies obtained fell to between 66 and 180, so that the atmosphere was nearly 90 per cent. purer after the snowfall than it was before.

Anti-Rabic Vaccination at the New York Pasteur Institute.

THE statistics of anti-rabic vaccination at the New York Pasteur Institute for the years 1900 and 1901 (a), which have been recorded by Dr. George G. Ramond, furnish interesting reading, which we would commend to the attention of those who scoff at the utility of such institutes. In all, 241 persons were treated, with one death, or a mortality of 0.41 per cent. Of these, thirty-three were bitten on the head, 162 on the hands, and forty-six on other parts of the body. In eighty-eight cases the animal which had inflicted the wounds was proved to be rabid by experimental inoculation, or by having caused the death of other persons or animals which it had bitten. In sixty cases the animal was declared rabid by veterinary examination. In ninety-three cases the animal had disappeared, or had been killed after having acted in such a manner as to lead one to suspect hydrophobia. Patients are admitted for treatment only

(a) *Medical News*, April 5th.

when there is strong evidence that the animal which bit them was rabid, and in about ninety of the last mentioned ninety-three cases the animal had shown all the clinical symptoms of rabies. The case which ended fatally was that of a little girl, aged seven years, who was bitten on June 13th, 1901. She had three cuts on her face; one on the lower lip, one on the nose, and one just below the left eye; all the wounds had bled freely and were cauterised with nitric acid within fifteen minutes. The patient was treated during twenty-three days from June 14th to July 6th. She developed symptoms of hydrophobia on August 29th, and died on September 1st.

An Early Sign of Pleurisy.

PHYSICAL examination often fails to afford trustworthy information in the early stages of pleurisy with effusion, but there is one sign which, according to Dr. Prjevalsky, of Kharkow, is pathognomonic of impending effusion. This is narrowing with increased resistance of the intercostal spaces on the affected side, and the phenomenon is especially well marked in children. This narrowing of the intercostal spaces is due to muscular contraction analogous to the muscular rigidity observed in association with inflammation of joints in the extremities; in other words, it is probably a reflex contraction constituting an attempt on the part of the organism to secure mobility.

The Anatomical Factor in the Production of Baldness.

THE scalp, properly so called, is limited to the soft parts which cover the vault of the cranium above the level of the temporal ridges and the superior curved line of the occipital bone. It comprises the skin, the subcutaneous fatty tissue or superficial fascia, and the occipito-frontalis muscle with its epicranial aponeurosis. This area corresponds pretty closely to what we may call the area of baldness, and it corresponds even more accurately to the area of the epicranial aponeurosis, a structure in which there are no muscular fibres nor any underlying muscular fibres between it and the bone. According to Dr. G. Elliott, of Toronto (a) this anatomical condition explains the occurrence of baldness. He dismisses as inadequate the usual explanation of interference with circulation due to the pressure of the hat, and attributes the principal rôle to the absence of exercise of this area of skin, the effect being to hinder the return of venous blood and lymph. The influence of civilisation is in the direction of restraining the action of the occipito-frontalis and facial muscles and of wearing the hair short, and under these circumstances the muscular exercise of this area is reduced to a minimum. He is of opinion that the comparative freedom of women from baldness is due to the careful way in which the hair is manipulated, such movements giving exercise to the scalp. The dressing of the hair in the male is such a short and, indeed, trivial operation that it affords

no relief of the kind, and the hairs die of venous asphyxia. Obviously, if this view be correct the proper treatment is systematic massage of the scalp from youth upwards thus securing a freer drainage of lymph, and an improved venous circulation. Dr. Elliott does not quote any observations of his own in support of his theory, and this is a pity because, before entering upon a course of gymnastics of the scalp involving so much trouble, one would like to have some sort of experimental assurance that good is likely to result. A man who massaged his scalp night and morning for ten years without any success would have a moral claim to damages against the author.

Latent Appendicitis.

THE diagnosis of cases of appendicitis, which run an atypical course, is often attended with the greatest difficulty, and may be quite impossible to make until the disease has passed the stage in which surgical interference is any longer of use. Dr. Samuel M. Evans, of New York, has recently recorded a case, the details of which are most interesting. The patient, a girl, aged nine years, was ill for five days and then died. During this time the temperature remained normal until about thirty hours before death, when it rose to 102° F. Her pulse, however, increased in frequency at the rate of about twenty or thirty beats a day. Throughout her illness there was no definite or localised pain or tenderness in the abdomen, nor was there any rigidity of the abdominal muscles—in fact, at no time were there any of the cardinal signs or symptoms of appendicitis present. At the post-mortem examination, there was evidence of recent peritonitis, and the peritoneum, especially in the region of the appendix, was covered with a purulent exudate. The appendix measured 6.2 cm. in length, had a large and patent lumen, and was of a dark bluish colour towards the tip. Its interior was filled with a thin dark-coloured pus, and the mucosa was gangrenous in spots, though no points of perforation through the peritoneum were present. The mesenteric lymph glands were enlarged, and on microscopic examination they showed numerous foci of necrosis, and in these areas many bacteria were demonstrable. The case is of interest in that there was a gangrenous appendix with no obstruction to its lumen, and that purulent peritonitis had taken place without perforation, all this, too, occurring without any localising symptoms during life.

The Treatment of Severed Ureters.

THE surgery of the ureter continues to excite the liveliest interest in the minds of surgeons and gynaecologists. The time has passed, when the operator who finds that he has accidentally divided the ureter, can immediately proceed to remove the kidney as the best treatment for the conditions he has induced. The fundamental questions which suggest themselves to the mind of all who reflect on the subject of the best methods for dealing with severed ureters are chiefly—

(a) *Journ. of the American Med. Assoc.*, March 29th, 1902.

How can exit be provided for the secretion of the kidney, with least risk of leakage, subsequent narrowing of the ureter, and ascending infection to the kidney? Putting aside the treatment by nephrectomy and that of occlusion of the proximal end of the ureter by ligature, we are limited generally to the adoption of one of two main lines of treatment. Union of the ends of the divided ureter by one of the many ingenious methods proposed may be effected in suitable cases, or the upper end may be made to open on to the skin or into a mucous tract, bladder, intestine or vagina. In the first place the risk of ascending infection is minimised, in the second the risk of narrowing of the ureter or leakage is reduced. At present most authorities will probably agree that generally uretero-ureteral anastomosis is the best treatment for cases where the ureter has been divided in the upper part of its course and implantation into the bladder when the division is in the lower part. We have been surprised to find that in a recent paper by Dr. W. R. Nicholson (a) on this subject no mention whatever is made of Mr. Henry Morris's work, though liberal reference is made to the work of others.

Phthisiophobia.

In the eagerness to eliminate phthisis from the community, it is perhaps unavoidable that enthusiasts should occasionally err from excess of energy and stumble into the use of exaggerated forms of language and hinder progress by lack of tact and consideration for ancient prejudice. In dealing with phthisical cases, it is needful that a wide angled lens should be allowed to mental vision, and that the sociological, international and humanitarian aspects should not be forgotten. As Mr. Malcolm Morris neatly puts it, "it is not scare but cure that is wanted." The United States Government has been badly advised in enforcing measures which cannot fail to have the effect of branding phthisis as a dangerously contagious disease. Phthisis is not to be considered a monster to be fled from but a danger to be effectually overcome. Whilst an encouragement is to be given to every earnest and intelligent measure aiming at the prevention of the spread of tuberculosis, exaggerated statements and precipitate action will only result in havoc to the sufferers and injury to the community. Phthisiophobia is an enemy to rational progress and must be treated as such.

Street Music and Seaside Invalids.

LAST week we commented on the inconvenience to invalids at seaside resorts arising from the disturbance of itinerant "music" in the streets. Those remarks were based on the communication of a medical man recently in charge of a patient at St. Leonards. The case was a critical one, and sleep was absolutely essential to recovery, yet several times in the day the patient was roused by the

sudden crash of a piano-organ outside the window. That situation, we venture to think, is sufficient to warrant our advice to St. Leonards to follow the example of Bexhill and to exclude itinerant music from the town. St. Leonards owes its existence to invalids. The *Daily News*, with a good-natured air of superiority, has taken the trouble to remind us that there are many healthy visitors, "trippers" and otherwise, who love music but who cannot afford to pay the pier dues to listen to the town band. If the passing gratification of a few street tunes is to be purchased by the sufferings of many invalids we should at once vote against the former. If the excursionists want music and are willing to pay for their luxury let the strolling musicians be confined to the sands, which we may remind the *Daily News* do not fall under the denomination of streets. If, however, the itinerant musician is to be allowed to parade the streets of the town and to startle the sick and the dying from their fitful and uneasy slumbers, then we say that any prudent local seaside authority will do well to prohibit any such indefensible and gratuitous outrage upon good sense and humanity.

A Turpentine Catastrophe.

AN action was tried in the High Court on Friday last in which a lady claimed damages from the Buckeye Bath Cabinet Company under somewhat peculiar circumstances. It seems that the instructions, for the use of the cabinet, which is a sort of portable vapour bath, comprise the discretionary use of turpentine, a certain quantity of which is to be placed in the water heated by a spirit lamp therein. The plaintiff complied with the instructions, with the natural result that the turpentine, which, of course, floats on the water and is evaporated first, formed an inflammable vapour. This took fire and inflicted serious injury on the unhappy patient, whom the jury invited to console herself with damages to the extent of £100.

Small-pox and Tramps in the Midlands.

It will be a matter of surprise if the present London epidemic of small-pox be not reproduced on a lesser scale in various parts of the United Kingdom. At the present time there are at least four cases in Birmingham, several more in West Bromwich and Tamworth, and nine at Walsall. The agency of infection has in nearly every instance been traced to tramps who have brought the disease either to common lodging-houses or to the casual wards of workhouses. Under these circumstances it is not to be wondered at that the local Poor-law authorities have been seriously considering the question of how best to deal with the tramp. Vaccination and re-vaccination cannot be insisted upon compulsorily. As a class, tramps are remarkable for their strong anti-vaccinationist views, and are recruits to a man for Mr. Arthur Balfour's noble army of conscientious objectors. The fact remains, however, that they menace the safety of every town and district of the United Kingdom by

(a) *American Journal of the Medical Sciences*, April.

the importation of small-pox. The Drayton Union made a crafty but unsuccessful attempt to induce the casuals to submit to re-vaccination by excusing them from the usual labour. It is reported that not a single tramp in the Midlands has so far surrendered to the blandishments of the Guardians so far as re-vaccination is concerned. It would be well for Parliament to render vaccination and re-vaccination compulsory in the case of tramps as a measure of protection to the health of the general community—notwithstanding the underlying principle of recent retrograde Vaccination Acts.

The London Fever Hospital.

THIS useful institution celebrates its centenary this year, and the occasion is an opportune one to call attention to the immense service which it has rendered to the Metropolis. During the last hundred years no less than 80,000 patients have been treated within its walls, suffering for the most part from scarlet fever or diphtheria. The special rôle of this institution is to provide hospital accommodation for persons who, while unable to defray the heavy cost of home nursing and medical care, are able and willing to contribute at any rate a substantial part of the cost. It is, in short, a pay hospital for infectious cases. Its importance has, of course, somewhat diminished since the organisation of that huge and costly undertaking, the Metropolitan Asylums Board, but it still offers an asylum in sickness to those who are unwilling to be maintained out of the rates or who desire a higher standard of comfort than a public institution can reasonably be expected to provide. As the aggregate of the fees received from patients amounts to only about one-fourth of the working expenses it is obvious that outside help is indispensable to its maintenance, and an appeal on behalf of the funds has just been issued by the president, Lord Balfour of Burleigh.

The Glasgow Barmaid Question.

THE final decision of the Glasgow Licensing Court has been given with regard to the employment of barmaids. It appears that a similar recommendation to the present was brought forward two years ago, but not in quite so far-reaching a manner. As now adopted, in future the instruction is that licence-holders shall not employ females as attendants behind the bars of public-houses, theatres and bars generally used by the public, excepting females who are attending personally to their own shops, or wives or daughters of licence-holders, or female assistants attending to the dining-tables in licensed premises where a *bona fide* business is carried on. The magistrates do not object to females attending private or service bars in hotels and restaurants, and they exempt railway refreshment-rooms where a *bona fide* restaurant business is carried on. In announcing this decision in Court Sheriff Lees stated that one of the reasons of the magistrates' action was to protect the interests of the barmaids themselves. He mentioned that a deputation of ladies had represented to the Lord

Provost that the average respectable life of a barmaid lasted only three years. So far as the unhealthiness of the occupation is concerned the point was dealt with somewhat fully in a leading article in the last number of THE MEDICAL PRESS AND CIRCULAR. This energetic and sensible action of the Glasgow licensing authorities may serve to remind other towns in the United Kingdom that they possess a considerable amount of control, direct and indirect, over the drink traffic in their midst. We must, however, be temperate even in well-doing. It must not be forgotten that certain risks attend the somewhat precipitate action of the Glasgow magistrates. To suddenly deprive a whole category of comely young women of the means of gaining a livelihood without providing them with an alternative is to save them from Scylla at the risk of their being sucked down by Charybdis. Dropping metaphors, it is evident that under pretext of safeguarding the virtue of these interesting young persons, the Glasgow magistrates have inadvertently condemned many of them to the sacrifice thereof.

Small-pox in London.

THE slight fall in the number of patients under treatment in the Metropolitan Asylums Board that took place the week before last has been more than compensated by an increase of patients. On Saturday last the returns showed 1,550 patients under treatment. At the same time, it is encouraging to note that the deaths were less during the past week than they had been during the three weeks preceding. On Saturday last, the 26th inst., thirty-eight fresh cases were reported from various districts within the larger London area. So large a number of fresh cases in a single day emphasises the fact that the epidemic has still to be reckoned with, as later figures of fresh cases show on Sunday 23 cases, and on Monday 31.

Street Collections.

THE street-collecting nuisance is one that affects alike all parts of the United Kingdom. Some years ago it reached its height, so most people fondly imagined, and since then our streets have been comparatively free from this objectionable form of "cadging," if we may venture to use a homely but expressive term. The greatest blow dealt to street collections was the definite abandonment of that policy some years since by the Hospital Saturday Fund, although by so doing they ran the risk of cutting off a large source of income. The objections to this method of raising money are manifold. Now that street collecting has been abandoned by all the more respectable societies—those who give money to street collectors, do so with their eyes open to the dangers of the situation. To put the matter in a nutshell, the public have for the most part absolutely no guarantee of the *bona fide* of any organisation that adopts this questionable method of raising alms from the charitable. From our point of view, the police should satisfy themselves as to the responsible nature of any street collection, before

sanction is given to that form of street begging. These remarks have been prompted by a recent invasion of the Metropolis by a particularly aggressive outbreak of this social nuisance.

The Summer Decline of Small-pox.

THE seasonal curve of small-pox has acquired a peculiar interest now that the disease has established itself in the metropolis, whence it has infected many other parts of the United Kingdom. It is a well-marked curve, and the mean result of observation, extended over forty years, has established in it certain definite features. The period of greatest mortality, for instance, is from January to May, while that of the least mortality is in September and October. Between December and July the deaths from small-pox are above the mean average mortality. In May a small decline is first shown, and is maintained steadily through June and July, when it makes a rapid fall, and is at zero until October, when it creeps up again to a moderate height in December, and then springs to a maximum in January. All this of course represents the average prevalence, which may be subject to considerable variations in particular years. The seasonal summer decline that commences in May, however, has a special comfort and significance in the case of the present outbreak that is raging in London. Within the past fortnight there has been a distinct fall in the total number of patients, and although the figures have again risen there is nevertheless reasonable ground for trusting that the fluctuation points to the approaching fall. It seems too much to hope that there will be a very marked decrease before July or August.

Report of the Rotunda Hospital.

THE report of the Rotunda Hospital, which was presented to the Obstetrical Section of the Royal Academy of Medicine in Ireland at a recent meeting, shows to all who care to learn from it the steady manner in which the ancient reputation of the Dublin School of Midwifery is being maintained and added to. The Master of the Hospital was able to furnish the statistics of 1,616 cases of labour delivered in the intern maternity with three deaths, one of which was due to advanced phthisis, and of 2,175 cases delivered in the extern maternity with four deaths. From the time that Dr. Collins, when Master of the Hospital in 1828, anticipated Smielweis in the use of chloride of lime, the Rotunda Hospital has always led the van of obstetrical advance, and consequently no one will be surprised at the results which have been obtained during the past year. This makes it all the more important—a fact to which we drew attention last year—that the statistics of the hospital should be placed before the medical profession in a more orderly and systematic manner, and in one which will, as far as possible, avoid the many pitfalls which surround all statistical records. We cannot, unfortunately, afford space to criticise Dr. Purefoy's report in detail. The most glaring incongruities which strike us are the large proportion of cases of

accidental hæmorrhage which occur at the Rotunda Hospital—37 out of 3,791 cases, or just one per cent.; the proportion of cases of abortion which require curetting—200 out of 286; and the lack of any apparent connection between the dimensions of the pelvis in cases of contracted pelvis and the difficulties of the labour. These points, however, must not be permitted to draw our attention away from the more important fact—the low rate of mortality.

Inspection of the Ears of School Children

AN interesting and important report was laid before the Otological Society of the United Kingdom at its last meeting by Mr. A. H. Cheatele on the results of the examination of the ears of 1,000 school children. The investigation was undertaken with the objects of ascertaining the amount of ear disease in children of the poorest class, and, if necessary, of drawing attention to the subject. Various tests were adopted, into which we cannot enter, save in the case of the meaning placed on the term "normal." By this was meant that the membranes appeared normal, and that the whispered voice could be heard at a distance of 18 feet. Inability to pass this test with one or both ears was present in 520 out of 1,000 children. Foreign bodies were found in the ear in 18 cases, of which 12 were girls. Out of 166 cases of deafness there were adenoids in 141; 335 of the total number of children had discharge from one or both ears, and in 88 cases the discharge was suppurative. The number who had previously suffered from middle ear discharge was 247, and of these 171 had adenoids, and perforation was present in 57, while adenoids were present in all in 434 children, of whom 394 presented some aural troubles. Mr. Cheatele finally raised the question as to what steps should be taken in the matter by the authorities. He recommended that the systems employed in Germany, Switzerland, and Sweden should be investigated and reported upon. The Society determined to appoint a committee, consisting of the President, the two Secretaries, Mr. Arthur Cheatele, Dr. Macnaughton-Jones, and Dr. Permewan, to further investigate the matter and to report.

The Traditional Winding-sheet of Christ.

A COMMUNICATION of deep interest has been brought before the last meeting of the Academy of Sciences in Paris by M. Vignon. This distinguished scientist has photographed the traditional winding-sheet of Christ, which has long been preserved at Turin. Its texture shows evidence of having been impregnated with oil and aloes, and M. Vignon has shown that a cloth so treated will receive a permanent impression from exposure to ammoniacal vapours, such as would be given off from a cutaneous excretion exceptionally rich in urea, as occurs in the case of a person who suffers a prolonged and painful death. The impressions on the texture in question have been found to act as a true negative, and have given distinct photographic pictures, displaying the marks on the head made by the crown

of thorns and the exuding blood - drops, the spear wound on the side, and the imprint of the stripes inflicted in flagellation. These latter present the special features of an enlargement at the end of each such as would be produced by a thong with a ball of lead at the extremity. It is known that such a form of scourge was used by the Roman soldiers of the period. A specimen has been found in one of the ruins of Pompeii. The marks of the nails in the upper extremity show that they were driven through the wrist—not the palm of the hand. The record impressed on the winding-sheet must, pretty certainly, have been due to chemical action, and not to the direct influence of light. But it has been shown of recent years by Dr. Russell that almost all objects affect the photographic plate in the dark. When Abney, some fifteen or twenty years ago, photographed a black hot kettle in a dark room he made a sensational record; but this result has since been left far behind. The results obtained in the present case by M. Vignon will necessarily fix the attention of scientific Christendom for some time to come. They offer another example of the meeting of extremes: the hard materialism of the questioning science of the present age with the original main-spring of the religious teaching which has so long dominated the civilised world. The ideas of emanations of light and illuminating vapours from the dead body are, however, of old belief.

A Case of Reported Catalepsy—Asleep Nineteen Years.

FROM the neurotic land of France comes, at present date, reports of a case of catalepsy—female, of course—of which the subject has lain for nearly nineteen years without displaying any obvious evidence of life other than the beating of the heart. In noticing this case a Dublin evening paper calls attention to an Irish one, where a religious young man of the county Mayo lay down on a September day of 1836 and slept for four years. During the whole of this period he tasted neither food nor drink. On the restoration of his faculties he informed the visiting clergyman that he was “fed by the Word.” It is interesting, if not always satisfactorily instructive, to observe the periodic occurrence of these phenomenal sleepers—down through all the centuries. Probably all our readers are familiar with the original Rip Van Winkle case—that of the boy Epimenides, who, tired with heat and work, turned into a cave, shady and cool, where he slept undisturbed for fifty-seven years, found great difficulty in recognising or being recognised by his former acquaintances on emerging, and lived on, hale and hearty, to the venerable age of 175; thus far the elder Pliny. Also with the compound case of the Seven Sleepers of Ephesus, who, in the heat of the persecution waged by Decius against the Christians of his empire, retired from prospective martyrdom to the depths of a cave in Mount Cœlius, where they slept safely for a time of 196 years. Some eminent

naturalists—as well as theologians—of the seventeenth century tell us of the inhabitants of a certain region of Muscovy. “There is a certain people that inhabit Lucomoria, a country of the further Sarmatia, who yearly upon the 27 day of the month November, after the manner of swallows and dogs, by reason of the intenseness of the winter cold, seem to dye. Afterwards at the return of the Spring, upon the 24 day of April, they again awake and arise.”

AN order has been issued by the London County Council prolonging the requirement to notify cases of chicken-pox for another six months.

PERSONAL.

DR. F. W. EVANS, of Cardiff, was thrown out of his trap a few days since, and sustained a severe shaking, one of the wheels having passed over him.

MR. E. T. WILLIAMSON, M.D. (London), F.R.C.P. Lond., has just been elected an Honorary Assistant Physician to the Manchester Royal Infirmary.

THE Right Hon. H. H. Asquith will preside at the Festival Dinner of the London Medical Graduates' College and Polyclinic, which is to be given on Thursday, June 5th, at the Criterion.

THE Governing Body of the Jenner Institute of Preventive Medicine have appointed Major Ronald Ross, F.R.S., F.R.C.S., &c., who is so well known in connection with his researches on malaria, to be head of a new department in the Institute at Chelsea.

THE Council of the Royal Institute of Public Health have conferred the Harben Gold Medal for the year 1902 upon Professor William B. Smith, M.D., F.R.S., Ed. of King's College, late Medical Officer of the School Board for London, in recognition of his eminent services to the Public Health.

DR. ELLIOTT SMITH, Professor of Anatomy at the Medical School of Cairo, has been accorded two months' leave of absence in order to allow of his proceeding to Girga, in Upper Egypt, to investigate some human remains recently discovered there, taken from a cemetery which is said to extend over a period of 8,000 years.

THE SERVICES.

INDIAN MEDICAL SERVICE.

LIEUTENANTS to be Captains.—J. C. H. Leicester, M.D., H. Innes, W. S. Willmore, A. E. Walter, C. Hudson, L. T. E. Hutchinson, C. F. Weinman, H. M. Cruddas, A. M. Fleming, E. L. Ward, J. N. Walker, V. H. Roberts, J. E. Robinson, G. King, T. S. Ross, G. P. T. Groube, P. P. Atal, W. MacM. Pearson, D. C. Kemp.

INDIAN SUBORDINATE MEDICAL DEPARTMENT.

To be Senior Assistant Surgeon, with the honorary rank of Lieutenant.—First Class Assistant Surgeon M. O'Mealy.

ARMY MEDICAL SERVICE.

THE King has been pleased, by Royal Warrant dated March 24th, 1902, to approve of the Surgeon-General, who holds the appointment of Director-General Army Medical Service, ranking as a Lieutenant-General.

THE first *conversazioni* of the Royal Society for this session will be given at Burlington House on Wednesday, May 14th.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

HEALTH OF EDINBURGH.

SIR HENRY LITTLEJOHN'S admirable annual report on the health of the city for 1901 has again appeared in the form of a folio of 74 pp., copiously interspersed with tables and charts. There is not this year any such outstanding feature in his report, as, for instance, his discussion of tuberculosis and the means to be adopted for its repression, in last year's report; but he continues to report steady all-round progress in matters hygienic. The figures of last census are now partially available, so that birth and death rates can be calculated more accurately than on the former basis of an estimated population. Taking the fact that a large increase in the population was due to extension of the city boundaries into consideration, we find that the rate of increase has been 14.75 per cent. in the decennium just closed, which compares favourably with the rate of increase in other large cities. The increase in the number of occupied houses has not taken place uniformly, those with rentals under £10 being fewer than last year by nearly 500. Sir Henry considers that this is due, not to increasing prosperity, but to the fact that many persons have been driven to find accommodation in sub-let rooms, or have gone to over-crowded other already occupied dwellings. Edinburgh, however, is in the fortunate position of having the largest number of rooms per inhabited house of any town in Scotland, and (except Perth) the smallest number of persons per room. The birth-rate during 1901 was only 24.99, by far the lowest ever recorded in Edinburgh, and the fall was in excess of that generally throughout the country, and of what could be accounted for by the war and other temporary conditions. From a table appended it seems that the rate has fallen fairly steadily from 33.4 per mille in 1861 to 26.24 per mille in 1900. The actual mortality, excluding "country deaths" was 17.76 per mille, a satisfactory figure. The highest rate was 22.8 in the second week of March; the lowest 12.5 in the beginning of October. The census has enabled a more accurate calculation of the death-rate in the various municipal wards to be made than was possible in recent years, and from the statistics it appears that as the seven most densely populated districts (with a population of 100 per acre or over—in one case 254 per acre) the mean death-rate was 19.22, whereas the mean death-rate in the other nine wards was only 15.70. The deaths from zymotic diseases amounted to 599—nearly double the figure of last year. The great annual fluctuation of the zymotic death-rate is due entirely to the prevalence or non-prevalence of measles and whooping-cough. Six cases of small-pox occurred during the year, with one death. The patient is said to have been vaccinated in infancy, but no marks were found. The measles death-rate last year was .53 per mille; that of scarlet fever .08; that of diphtheria .17; that of whooping-cough .89. The mortality of illegitimate children has a special paragraph devoted to it. Out of 558 illegitimate births no fewer than 154 died before attaining the age of one year; or, in other words, if 1,000 illegitimate children had been born 274 would have died before reaching the end of the first year, whereas in the same number of legitimate children the number of deaths was only 132. A large proportion of these illegitimate children die from causes which "to a certain extent must be regarded as preventable, and it comes to be a question whether in future some effort should not be made to give these infants a chance of surviving their first year, at least as good as that possessed by the more fortunate children born in lawful wedlock."

During the year fourteen cases of typhus fever occurred, and the experience of former years is confirmed that no infectious disease "appears to offer such great difficulty in diagnosis," with the result that the first case in a family is seldom recognised, "and it is as a rule the notification and removal to hospital of a patient suffering from 'typhoid fever' which first leads to the

discovery of the existence of the disease, and of the fact that other members of the family have been ill with 'influenza' beforehand." It is difficult to account for the very great spread of diphtheria during the last two years; the increase was not due to any localised epidemic, but was distributed equally throughout the year. While the oldest inhabited portions of the city furnish the greatest number of cases from typhoid, it is the more recently built, and apparently more sanitary, dwellings in which the chief incidence of diphtheria occurs. Sir Henry has endeavoured, in vain, to discover any cause for the prevalence of diphtheria. Although small-pox was so prevalent in Glasgow no case occurred in Edinburgh till February 19th, and, in all, only six cases were found. Every precaution was taken to meet the danger, and facilities for free vaccination were widely afforded and taken advantage of. The cost of revaccination in Edinburgh during February, March, and April last was £3,207, and for this sum a total of 29,903 persons were revaccinated. The attack-rate and death-rate of scarlet fever continue steadily to decrease, and it seems as though notification and hospital isolation were, at last, making a real impression on its customary prevalence. Measles has during the last three years upset all Sir Henry's previous experience, inasmuch as while it used consistently to show a marked biennial periodicity, the years 1899, 1900, and 1901 have each been visited by an epidemic. Speaking of the bacteriological examination of morbid products, Sir Henry points out that in no fewer than ninety-two out of 124 suspected cases of typhoid, and 190 out of 268 suspected cases of diphtheria the examination negatived the existence of these diseases, and thus prevented the expense and discomfort of removing a considerable number of patients to the Fever Hospital. The report is altogether a model of what such a document ought to be. Concise, clear, suggestive, and giving a definite idea of how public health matters are progressing in the city, it will be read with equal satisfaction by those whose interests are purely medical, and those whose interests are entirely municipal.

Belfast.

[FROM OUR OWN CORRESPONDENT.]

THE Spring Meeting of the North of Ireland branch of the British Medical Association was held at the Museum, Belfast, on Thursday last, the 24th inst. The President, Dr. J. Singleton Darling (Lurgan), occupied the chair. The Council Report announced the election of three new members.

The President read notes of two cases of "Pernicious Anæmia," and Dr. Clarke (Bessbrook) related the history of two further cases. Professor Lorrain Smith and Dr. Thos. Houston made some remarks on these cases, which seem to be very frequent in Ulster.

Dr. St. Clair Boyd read notes of one case, Dr. Tennant of one case, and Dr. Dempsey of two cases of "Extra-Uterine Fætation," all showing specimens. Professor Sinclair reported a case of simultaneous appendicectomy and transverse colectomy which terminated in recovery. Dr. J. B. Moore, who had seen the case, adding some remarks. Mr. Robert Campbell read notes of a case of acute intestinal obstruction by a band in an elderly woman, Professor Sinclair and the President and Dr. Martin (Portrush) afterwards discussing the case.

Dr. Calwell read notes of (a) A case of "Tetany in Dilatation of the Stomach"; (b) A rare form of relapse in typhoid fever, and of a second attack after a few months' interval; (c) On the nitro-propiol test for sugar in urine, with reports of 100 examinations.

POST-GRADUATE LECTURES.—A prospectus has been issued of several post-graduate courses to be held at Queen's College, Belfast, in the summer session. Professor Lorrain Smith will hold a class in bacteriology on Monday, Wednesday, and Friday of each week during the session at 4.30 p.m., as he has done for several years past. Some seventy medical men have taken this class in the last few years with great pleasure and profit to themselves. This year there is to be a second course as

well, on the pathology of diseases of the blood, in which Professor Lorrain Smith will be assisted by Dr. Thos. Houston. This class will be held on Monday and Friday, at the same hour as the other.

Another new departure is a series of sixteen lectures by Professor Symington, on the advanced anatomy of the nervous system. These lectures will be given on Tuesday and Thursday afternoons at five o'clock, and are intended to serve as an introduction to a course of pathological neurology to be held in the summer of 1903.

Literary Notes and Gossip.

SIR FELIX SIMON has republished his lectures "On the Principles of Local Treatment in Diseases of the Upper Air Passages," with two other lectures which recently appeared in the *British Medical Journal*, as an appendix.

THE new edition of the "Pharmacopoeia of the Central London Throat and Ear Hospital" is a most complete little book of its kind, and will be acceptable to the general practitioner, who has not always at his fingers' ends the most suitable gargles, paints, lotions, and drops for the various organs.

THE new edition (sixth) of Professors Delafield and Prudden's "Text-book of Pathological Anatomy and Post-mortems" is now before us, in its new dress, with nearly 500 illustrations in black and colours. It is undoubtedly the best illustrated and most up-to-date work on the subject now before the profession.

THE sixth edition is announced for next week of "The Practitioners' Handbook of Diseases of the Ear and Naso-Pharynx," the multi-authorship of which is shared by Messrs. H. Macnaughton-Jones, W. R. H. Stewart, and Herbert Tilley, of London; Messrs. Ambrose, Birmingham, and Robt. D. Joyce, of Dublin, and Dr. Wm. Milligan, of Manchester.

THESE appears to be an unlimited supply of books, great and small, on the Vermiform Appendix, of late. The demand, however, does not seem to keep pace with the supply, no new edition being announced as in the press; we hope, therefore, that that much maligned organ has been found on prolonged investigation to be more sinned against than sinning.

THIS being the season for garden work, those of our readers who take an interest in floriculture and horticulture will be glad to possess themselves of Barr's new "Seed Guide," which in the space of 112 pages contains a list of all known seeds and plants which thrive in this country, with cultural directions and practical hints of great value to the amateur gardener, together with a list of books useful for garden purposes. Messrs. Barr (King Street, Covent Garden, London) will send this guide free to any of our readers on receipt of name and address.

DR. CULLINGWORTH'S "Short Manual for Monthly Nurses" is a most useful little book, and may be safely recommended to both nurse and student. It will instruct the nurse in all the necessary details of monthly nursing. Its practical simplicity is a point of value; the nurse does not want to have impressed upon her knowledge of theoretical value only, but requires simple, practical teaching in the management of a confinement, with the subsequent nursing of mother and child, and this, as we have said, she will find herein.

AN interesting work on General Buller's campaign with the Natal Field Force has been just published by Mr. Brimley Johnson. It is written by Lieutenant E. Blake Knox, M.D., B.A.M.C., who was through the Natal campaign, and contains a full description of the engagements of Spion Kop, Vaal Krantz, Monte Cristo, Onderbroek and Langerwaakte Spruits, Pieter's Hill, Biggarsberg, Botha's Pass, Allemans Nek, Amersfoort, Geluk, Belfast, Lydenberg, Badfontein, Mauchberg, and many minor engagements. Special reference is made to "First Aid" work in the field, the conduct of the hos-

pitals, and the general medical and surgical aspect of the campaign.

WE are asked to announce that the Religious Tract Society will publish on May 1st, the authentic and complete life of James Chalmers, the great New Guinea Missionary. To the Rev. Richard Lovett, M.A., has been entrusted the biography and he has been assisted by the family of the late Dr. Chalmers, who have entrusted to him the whole of the letters, memoranda and reports in their possession, including an autobiography from the pen of Chalmers himself, which has been incorporated into the life. Dr. Lawes, his life-long colleague in New Guinea, Sir J. Erskine, of the Royal Navy, and a host of others have all co-operated in the effort to make this a true picture and a worthy life of one of the greatest missionary heroes of the nineteenth century.

TO overcome the morphia habit, without the intense and intolerable mental and physical suffering which always ensues if there is a sharp cessation with no treatment, is an obvious boon to the wretched morphinomaniac. Dr. Oscar Jennings, of Paris, who has just issued a second edition of "The Morphia Habit" through Messrs. Ballière, Tindall, and Cox, very honestly abstains from claiming universal success; many of his patients relapsed into the habit, but nearly always because they left him before the habit was broken and the will-power sufficiently strengthened. To ensure success the morphinomaniac must place himself entirely in the hands of his physician, whose resources will be taxed to the utmost to effect a cure. Cardiac depression, dyspepsia, mental irritation, sleeplessness, and a host of other evils have to be combated. It is decidedly a book to be consulted for the rational treatment of morphinism.

THE *Medical Register* and *Dentists' Register* for the current year are now available. The number of registered practitioners now stands at 36,912, of which 21,022 are resident in England, 10,303 in Scotland, and 5,087 in Ireland. The total shows an increase of 557 on the previous year, in comparison with 519 in 1900 and 779 in 1899. The Registrar is to be congratulated on the greater accuracy of the present issue as compared with some of its predecessors, diligent search having failed to reveal the names of any persons deceased before the end of 1901. We note, on the other hand, that the addresses are by no means always accurate, but this is probably the fault (or design) of the individuals. We gather from the *Dentists' Register* that there are 4,616 registered dentists in the United Kingdom, of whom 2,587 figure thereon in virtue of having been in practice prior to 1878.

DR. JELLETT'S "Short Practice of Midwifery for Nurses" (J. & A. Churchill) may be described as excellent. It embodies most faithfully the treatment adopted at the Rotunda Hospital, Dublin, and is throughout concise, accurate, and practical. Some may consider it to be too full for nurses, and to treat of subjects which concern only the doctor; yet to equip the nurse as an intelligent worker and efficient help to the medical practitioner a considerable amount of obstetric knowledge must be gained, much of which she can never use by herself. The surgical cleanliness both in cleansing her own hands, and in the examination of the patient, the cautions as regards douching and its condemnation, except when absolutely necessary, and the reduction *ad minimum* of the customary vaginal examination would, if carried out by the nurse, reduce enormously the risk of acute sepsis.

Beri-beri in the London Docks.

AN inquest was held at West Ham last week on the body of a seaman of a Norwegian vessel, *ex Seychelles*, who had died at the Seamen's Hospital of a disease diagnosed to be true beri-beri.

Death under Chloroform.

A LAD, aged 15, died under chloroform at the Durham County Hospital last week while undergoing the removal of enlarged cervical glands. Death was preceded by a severe attack of vomiting. The usual verdict was returned.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

NATALITY IN GREAT BRITAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Several suggestive letters have appeared in your columns discussing the above subject from the point of view of the philosopher and the sociologist. It would be interesting to know what the practical physician, and especially the gynaecologist, have to say about it. What is the effect on the physical and mental health of married women who, while gratifying their sexual appetites, adopt systematically effective means to prevent conception. What effect, if any, does this practice produce upon the female organs—the ovaries, the uterus, and the mammae—does it directly or indirectly give rise to disease? and if so, of what character?

That the practice in question has been more and more widely adopted within the last few decades no one having sufficient experience will, I think, doubt. Many young couples cynically agree from the outset to have no children; many more decide to limit their family to narrow numbers. Many young people must look forward with some apprehension to the responsibilities of parentage, but in the majority, when children come, the parental instinct is aroused and the children become a source of love and happiness. Many women have intense maternal feelings and are never so happy as when expecting a baby or when rearing a new addition to their brood. The effect upon the mind of wives made artificially barren no doubt varies very much in accordance with individuality; but it seems sufficiently evident that in the vast majority of cases it is better for a married woman's moral and mental health that she should have children, and have at least the opportunity of a call upon the qualities of love and self-sacrifice which are innate if latent in most motherly breasts. How does suppression of these wholesome emotions react upon the moral and mental health of the wife, and what is the effect upon the husband in like directions when instead of having children to appeal to the better instincts of his nature he has no care save in the gratification of his own selfish instincts and desires?

I am, Sir, yours truly,

A STUDENT OF MEDICINE.

April 24th, 1902.

NIGHT COUGH AND CHEAP CIGARETTES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—During the last two years a number of cases have come under my notice in the out-patient department of Sir P. Dun's Hospital of lads who have complained of being kept awake for "half the night" by a cough. It has been usually associated with a little "black spit," and inspection of the fauces commonly shows slight vascular injection of the parts. Examination of the chest reveals no abnormality, nor can any lesion be found, beyond the condition of the fauces to account for this distressing nightly coughing. Sometimes the principal complaint is made by the parent, who accompanies the lad, that no one in the house is allowed to get any sleep in consequence of the noise made by the boy. More cases of this kind have attended during the last six months than before, and it has been found very frequently that these boys are consumers of a certain brand of cheap cigarettes (which they usually regale themselves with after dusk) that it is difficult to believe the occasional boy who denies the impeachment. Confession is most readily obtained when the parent is absent, so that now the inquiry is generally postponed till a subsequent visit, should the lad be accompanied; as, of course, if he be obliged in self-protection to tell a lie at the start, it is reasonable to suppose he will stick to it afterwards.

I do not think it advisable at present to reveal the

name of the particular brand; others may perhaps have observed cases in which cough appeared to be induced by other brands. I have not risked a personal trial of a packet, so am unable to form a definite idea as to whether the cough be principally due to the very unseasoned condition of the youthful throats, or the virulence of the "tobacco."

Yours truly,

R. H. KENNAN.

69, Lower Mount Street, Dublin.

THE VAGARIES OF MEDICAL ETIQUETTE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The public dispute that has been so long raging over the alleged virtues of the *Lacnanthes* cure for consumption suggests a variety of reflections. First of all, there is no need to reject any possible means of cure because it comes from a man who has been struck off the Medical Register. If a person were unqualified, his claim to have introduced a new therapeutic method would not be rejected without fair trial, witness the hundred and one applications of electricity, light, heat, and other physical applications that are daily adopted by the profession, although produced by non-medical persons. The position of the latter, we take it, is equal to that of Mr. Alabone, now that he is struck off the roll of the College of Surgeons. Because he is no longer in the profession that is clearly no reason why his claims should be brushed aside in cavalier fashion by Sir William Broadbent, who was at once shown to be ignorant of the existence of the plant *lacnanthes*, which is widely used in America. If Alabone's name were removed from the Register because of a notice that appeared many years ago in *Moonshine*, has he not by now purged his offence? What is sauce for the goose is surely sauce for the gander. A coloured cartoon of a certain specialist appeared not long ago in *Vanity Fair*, with a description of the clubs he belonged to, and a glowing account of his skill in treatment of affections of the nose, throat and ears. Why should Alabone, in the suburbs, be condemned by the General Medical Council, as it were, to penal servitude for life, while the Harley Street specialist escapes with a shrug of the shoulders? Well may the public outside laugh at the vagaries of medical etiquette and of the inner life of the medical community.

I am Sir, yours truly,

COLONIAL PRACTITIONER.

Medical News.

French Hospital.

THE thirty-fourth annual dinner in aid of the funds of the French Hospital, Shaftesbury Avenue, was given on Saturday evening last, at the Hotel Cecil, the French Ambassador (M. Paul Cambon) in the chair, supported by the Lord Mayor, the Belgian Minister (Baron Whettnall), the Swiss Minister (M. Bourcart), the Serbian Minister, numerous other members of the diplomatic and consular services, and a large gathering of French and English interested in this medical charity. The Chairman, in proposing the toast of the evening, referred in terms of regret to the loss that the hospital had sustained in the person of the late Sir William McCormac. He spoke highly of the services rendered by Mr. Edmund Owen and Dr. George Ogilvie, and for the fourth year in succession it was his pleasure to sing the praises of Dr. Vintras, who had, he said, two children—the hospital and the convalescent hospital at Brighton. He added that the French Government had made a donation of 100,000 francs to the funds, which he hoped would largely benefit by the fêtes which were to be held at Earl's Court under the patronage of the Prince and Princess of Wales, to enable them to clear off their debts and place the institution on a firmer basis. The musical programme, which was deferred until after the toast list had been exhausted, comprised songs by Madame Hélène Palacsek, Signor Umberto Salvi, Miss Florence Venning, and Mr. G. Hodgson, under the direction of Chevalier Tito Mattei.

Medical Defence Union.

THE annual general meeting will be held on Thursday, May 15th, at the registered offices (4, Trafalgar Square, London), at 5 p.m., to receive the annual report of the council and the statement of accounts, together with the auditor's certificate for the past year; to elect three members of the council, Drs. Roche Lynch, Elliston, J.P., and V. Jaynes retiring (by ballot) but being eligible for re-election; to appoint an auditor, and to fix his remuneration; and to vote the necessary sum for payment of the travelling expenses to provincial members of the council for attendance at council meetings.

Dentist Qua Apothecary.

A HALIFAX registered dentist was last week fined £20 for practising as an apothecary. It appears that this enterprising person had acted as medical officer to the Halifax Friendly and General Aid Society at a salary of £150 per annum, with free house, rates, water, and gas, and had attended private patients as well.

Royal University of Ireland.

CONVOCATION of the Royal University of Ireland will elect, on May 9th, six members as representatives on the Senate in the place of the following who have retired at the end of their period of office, but who are eligible and who offer themselves for re-election:—Dr. J. Walton Browne (Belfast), Mr. Edward Cumming, M.A. (Dublin), Rev. Mathew Leitch, D.Lit. (Belfast), Judge Shaw, LL.D. (Dublin), Professor T. Sinclair (Belfast), and Sir William Thompson, C.B. (Dublin). Dr. Jeremiah Cotter, of Cork, has also come forward as a candidate, and consequently the election will be contested.

Torbay Hospital Affairs.

THE honorary medical staff of the Torbay Hospital recently kicked against the rule under which they were required to present themselves for election each year. After some acrimonious discussion, the governors have finally decided to abrogate the rule in question, and the outgoing medical officers have been reinstated. As a mark of disapproval, the minority of the board of Governors have resigned in consequence of this decision.

Plague in India.

ALTHOUGH the advent of hot weather is producing the customary diminution in the incidence of the plague, there are still about 14,000 deaths weekly in the Punjab. Delhi and Simla are free from the disease, and great efforts are being made to keep them so.

Mount Vernon Consumption Hospital.

THE recently published report of the Mount Vernon Hospital for Consumption is a valuable record of good work successfully accomplished in the interests of the phthisical. It is explained that the former name of North London Consumption Hospital has been given up in order to prevent confusion with the North London or University College Hospital. During the past year 578 cases have received treatment as in-patients and 4,699 new patients have been dealt with as out-patients. From the King's Hospital Fund £1,000 has been received. The chief event of the year has been the generous offer of a friend, who insists on remaining anonymous, to provide and partially endow a country branch and convalescent home. This noble gift of over £100,000 will do much for the amelioration of London's phthisical poor. Princess Christian lays the foundation-stone of the new sanatorium at Northwood on May 13th. The medical report contains much of value and interest, and should be carefully read by all interested in the study and arrest of phthisis.

Suicide of a Medical Man.

DR. ARTHUR KILLICK, of Seven Kings, near Ilford, was found with a wound in the region of the heart in a field near his home one day of last week, and in his pocket was a penknife covered with blood. A verdict of suicide during temporary insanity was returned at the inquest.

Death of a Crimean Veteran.

THE death is announced of Inspector-General Alex. Watson, M.D., who served in the Black Sea during the Russian War, and was present at the bombardments of Sebastopol and the capture of Kertch, and who was

mentioned in despatches for services at the capture of the Pei-ho forts in May, 1858. He was present at the attempted assassination of the Duke of Edinburgh, at Sydney, in 1868, when he abstracted the bullet and remained in attendance on his Royal Highness until his recovery.

Pass Lists.**University of Durham.**

AT the first examination for the degree of Bachelor in Medicine during April the following candidates satisfied the examiners:—

Elementary Anatomy and Biology, Chemistry, and Physics.—Wilfrid Fairclough, with first class honours; Oswin Shields, M.R.C.S., L.R.C.P., with second class honours.

Pass list.—Orrock Arnott, Frederick Laverick, Robert J. Weidner.

Elementary Anatomy and Biology.—Vincent E. Badoock, George E. P. Davis, William Denham, Henry Denham, George Denholm, Neville A. Eddlestone, Archibald Finlay, Arthur C. H. McCullagh, Geoffrey Pybus, William Rollin, Richard W. Swayne, Lionel L. Westrope, James B. Williamson, Thomas L. Wormald, Frank Whitby.

Chemistry and Physics.—Helen Y. Campbell, Hamilton Drummond, Camilla L. Heckrath, Florence B. Lambert, Arthur A. Miller, M.R.C.S., L.R.C.P., Jessie M. Murray, Samuel L. McBean, George H. Spencer, M.R.C.S., L.R.C.P.

Elementary Anatomy.—Lillie Johnson, B.Sc., John C. Pearce, A.Sc.

In the Second Examination for the degree of Bachelor in Medicine, the following candidates passed:—

Anatomy, Physiology, and Materia Medica.—Honours (Second Class).—Olga Schiele, Ernest Young, Reginald I. Douglas.

Pass list.—Reginald Bigg, M.R.C.S., L.R.C.P.; George N. Bigg, Dudley T. Birt, William H. H. Croudaes, John Galloway, Joseph H. Lewars, Herbert L. Noel-Cox, Robert B. Reed, Andrew B. Raffle, Robert J. Willan.

The following candidates passed the Third Examination for the degree of Bachelor in Medicine:—

Second Class (Honours).—Reginald Bigg, M.R.C.S., L.R.C.P.

Pass List.—Frederick D. Atkins, Frederick G. Armstrong, John A. Bell, Harold L. Currie, Margaret D. French, William Gibbons, Alfred H. Heslop, Walter Howard, Thomas C. Hunter, William Hughes, William H. Peacock, William J. Phillips, Donald M. Ross, Mary Raw, Constance C. Robertson, David R. Roberts, Fred C. Stoker, Andrew Smith, Thomas Y. Simpson, John M. Shaw, Otho B. Travers, William F. Wilson.

University of Aberdeen.

AT the graduation ceremonial on April 10th the following degrees were conferred:—

Degree of Doctor of Medicine (M.D.).—Archibald Campbell Barron, M.B., C.M., Robert Sinclair Black, M.A., M.B., C.M. (commendation), Henry Fraser, M.B., Ch.B. (commendation), Frederick Theobald Keyt, M.B., C.M. (honours), Alexander Gordon Milne, M.B., C.M., John William Myers, M.B., C.M., James Farquhar Philip, M.B., C.M.

Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—Lewis Davie Cruickshank (with First Class Honours), Robert Donald Keith, M.A., and Alexander Christie Reid, M.A. (with Second Class Honours), Louis Coetzee, James Bremner Elder, Harry Willmott Elwell, George Bruce Killoh, Jeannie Charlotte Macleod, Archibald Mahomed, James Burnett Rae, Alexander Robertson, Robert Boyd Robson, John Stuart Rose, Thomas Stewart Slessor, M.A., James Souter, M.A., Alexander Watt.

Diploma in Public Health.—William Fraser Bisset, M.B., Ch.B. Aberd., Frederick Theobald Keyt, M.B., C.M. Aberd., Ernest Hunt Nash, M.B., Ch.B. Aberd.

The Lord Rector's Prize in the Faculty of Medicine was awarded to Harry O. Nicholson, M.D.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ABORTIVE DISINFECTION.

AN amusing story is related by a Sheffield contemporary concerning the disinfection of a room in which a case of diphtheria had occurred. The medical man in attendance duly fumigated the room, which was sealed up for twenty-four hours, as is customary. In the course of a few hours a favourite cat was missed, and after a vain search in the neighbourhood the horrid suspicion grew that the unhappy animal must have been sealed up with the fumes. The door was opened, and out leaped the cat, in a state of much bronchial distress, from which, however, it soon recovered. The fumigator, however, pointed in tones of triumph to the fact that although the cat was not killed it was the only living thing in the room that escaped, even its parasites having been destroyed.

MISS L.—The fees levied by the Metropolitan Asylums Board on students who enter for the "course of fevers" are, in part, allocated to the medical superintendent, and the balance goes to cover the expenses in connection with the instruction. One great object in English medical education seems to be to extract a maximum of fees from students, and no opportunity is lost of putting this principle into practice. The principle is "quite English," for in other countries the State offers facilities for study without applying the thumb screw.

M. E.—"Sic" in journalism signifies, when placed after a word, that it is just so in the original. The term has no pathological meaning.

MOTOR CYCLES.

A COUNTRY PRACTITIONER would be glad to know if any reader, having experience of a motor cycle, can recommend the machine or doing medical rounds in the country, and if so which.

INQUIRER (Bristol).—The matter is still under consideration, and our correspondent will hear from us in the course of next week.

OMEGA.—No doubt some good would result from personally enlisting the sympathy of the individual members of the Council.

BIRMINGHAM CONSULTANTS AND THE WORKING CLASSES.

To the Editor of THE MEDICAL PRESS and CIRCULAR.

SIR.—While thanking you for your paragraph under this heading, will you be so good as to let me point out that the list of consultants and specialists has so far only been placed at the disposal of the Secretary of the Ebenezer Provident Sick Society?

I am, Sir, yours truly,

ROBERT SAUNDY.

140a, Great Charles Street, Birmingham,
April 25th, 1902.

Meetings of the Societies, &c.

LONDON.

THURSDAY, MAY 1ST.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Clinical evening. Cases and specimens by G. Hartridge, H. Grimsdale, W. Adams Frost, E. T. Collins, L. V. Cargill, George M. Thompson, Wm. Lang, and G. M. Thompson and A. Bronner.

ROENTGEN SOCIETY (20, Hanover Square, W.).—8.30 p.m. Mr. Ernest Payne will open a discussion on The Relation between "X" Rays and Allied Phenomena in Light and Electricity.

FRIDAY, MAY 2ND.

BRITISH ELECTRO-THERAPEUTIC SOCIETY (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Adjourned discussion on Dr. Squeira's paper on The Finest Treatment of Lupus, Rodent Ulcer, &c.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square).—5 p.m. Cases, specimens, and instruments will be shown by Dr. Bronner, Dr. Walker Downie, Dr. Jobson Horne, and Dr. Donelan.

SOCIETY OF ANAESTHETISTS (20, Hanover Square, W.).—8.30 p.m. Dr. Blumfield: On Some Points concerning Complete Relaxation of the Abdominal Walls under Anaesthetics. Dr. Flux: On the Use of the Open Stopcock.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Miller Hospital, Greenwich).—8 p.m. President's Address on Migraine. Smoking concert to follow.

POST-GRADUATE COURSES AND LECTURES.—Medical Graduates' College and Polytechnic (22, Chelsea Street, W.C.). Demonstrations will be given at 4 p.m. as follows:—Monday, skin; Tuesday, medical; Wednesday, surgical; Thursday, surgical; Friday, ear.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At 8.30 p.m. 1. Mr. S. Paget: "Notes on a case of Empyema, where washing out

the Cavity was followed by Epileptiform Convulsions and death." 2. Dr. Seymour Taylor: "Gall Stones and their medical treatment." 3. Mr. L. Bidwell: "Gall Stones and their surgical treatment." 4. Mr. J. R. Luon: "Notes of a case of Strangulated Femoral Hernia, Herniotomy, death from collapse following perforation of an ulcer just above seat of strangulation."

DUBLIN.

WEDNESDAY, APRIL 30TH.

IRISH MEDICAL ASSOCIATION.—Council Meeting, College of Surgeons, 4 p.m.

THURSDAY, MAY 1ST.

ROYAL UNIVERSITY.—M.B., M.Ch., M.A.O. Examinations.

FRIDAY, MAY 2ND.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Pathology, College of Surgeons, 8.30 p.m.

MONDAY, MAY 5TH.

ROYAL COLLEGE OF PHYSICIANS.—L.R.C.P. (registered practitioners) Examination.

ROYAL COLLEGE OF SURGEONS.—L.R.C.S. (registered practitioners) Examination.

TUESDAY, MAY 6TH.

CONJOINT ROYAL COLLEGE.—Examination for Diploma in State Medicine.

ROYAL COLLEGE OF SURGEONS.—Annual Election of Examiners.

Appointments.

EMERY-ROBERTS, E., M.B., Ch.B. Vict., Assistant Medical Officer to Mill Road Infirmary, Liverpool.

GIMBLETT, W. H., M.D. Durh., Medical Officer of Health of the Buckhurst Hill Urban District, Essex.

HARPER, ALEXANDER, M.D. Durh. M.B.C.S., Medical Officer to the Princess Alice Memorial Hospital, Eastbourne.

HORDEN, J. B., L.D.S. E.C.S., Honorary Dental Surgeon to the Leeds General Infirmary.

LAIRD, A. J., M.D. Glasg., Medical Officer of Health of the Borough of Crews.

RANSDEN, HERBERT, M.B. Lond., Certifying Surgeon under the Factory Acts for the Saddleworth District of the West Riding of Yorkshire.

RIDER, ALONZO G., M.D. Lond., Surgeon to the Royal Albert Hospital, Devonport.

ROBSON, R. B., M.B. Durh., Medical Officer to the Urban District Council of Alnwick.

ROBINSON, FREDERICK, L.R.C.P. & S. Irel., Police Surgeon for the County Borough of Blackburn.

SINCLAIR, W. J. H., M.B., C.M. Aberd., Medical Officer at the general prison, Barlinnie, by Glasgow, vice Dr. J. Maxtone Thom.

THOM, J. MAXTONE, M.B., M.S. Edin., Medical Superintendent of Glasgow Royal Infirmary.

WILLEY, FLORENCE E., M.B., B.S., B.Sc. Lond., Pathologist to the Royal Free Hospital, Gray's Inn Road, King's Cross.

Vacancies.

Abbeyleix Union.—Medical Officer. Salary £100 per annum, and usual vaccination fees. Also a Medical Officer of Health. Salary £20 per annum. Applications, with testimonials, to James Finnegan, Clerk of Union (Sec. Advt.).

Central London Sick Asylum District.—Assistant Medical Officer. Salary £180 per annum, with board and residence at Hendon Asylum. Applications to Fred. W. Bailey, Clerk, Clerk's Office, Cleveland Street Asylum, Cleveland Street.

Crooksbury Sanatorium for Open-air Treatment.—Assistant Medical Officer. Salary £100 per annum. Applications to Dr. Walters, The Sanatorium, Crooksbury Kidges, Farnham, Surrey.

Durham County Asylum.—Junior Assistant Medical Officer. Salary commences at £150. Apartments, board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Fisherton Asylum.—Assistant Medical Officer. Salary £150 per annum to commence, with board, lodging, and washing. Applications to Dr. Finch, Salisbury.

Kings Norton and Northfield Urban District Council.—Medical Officer of Health. Salary £500 per annum. Applications, "Medical Officer of Health," to Edwin Docker, Clerk of the Council, 10, Newhall Street, Birmingham.

Poplar and Stepney Sick Asylum District.—Second Assistant Medical Officer. Salary £100 per year with rations, furnished apartments and washing. Applications to Robert Foskett, Clerk to the Managers, Bromley, Middlesex, E.

Suffolk General Hospital.—House Surgeon. Salary £100 a year, with board, lodging, and washing. Applications to Henry Bonner, Secretary, Bury St. Edmunds.

Wanted for the Royal Cornwall Infirmary a House Surgeon. Salary £100, with board (excluding stimulants) and apartments. Applications to the Secretary, 4, Parkvillas Terrace, Truro.

Birth.

JACKSON.—On the 24th inst., at Carntyne, Hexham, Northumberland, the wife of John A. Jackson, M.D., of a son,

Marriage.

BOTHWELL-STUMKE.—At Bulawayo, on March 26th, George Granville Bothwell, M.B., C.M. Aberd., eldest son of the late G. G. Bothwell, M.B.C.S., L.R.C.P., of Topsham, Devonshire, to Stella, eldest daughter of Charles Augustus Stumke, Uitenhage, Cape Colony.

Original Communications.

A CONTRIBUTION TO THE STUDY OF MALIGNANT ENDOCARDITIS. (a)

By F. J. POYNTON, M.D. LOND., M.R.C.P.,
and ALEXANDER PAINE, M.D. LOND.

THE authors, while investigating the pathogenesis of rheumatic fever, had been led to the study of certain cases of malignant endocarditis which were associated with a history of acute rheumatism and in which, during the course of the disease, there were not infrequently active manifestations of rheumatic fever. In such cases there might be repeated rigors, yet after death no abscesses be found, no suppuration in the blood clot of aneurysms, and infarcts might be healing. They had collected thirty such cases from post-mortem records, all with a previous history of rheumatic fever, and in no case was there abscess formation. The relationship between these two diseases was evidently a very close one, and they thought malignant endocarditis was a preferable name to infective endocarditis, since it was now established that rheumatic valvulitis was also infective in origin. The researches of many distinguished investigators had clearly demonstrated the microbic origin of malignant endocarditis, and, further, that though various micro-organisms could cause this form of endocarditis, that a streptococcus was the organism which had been found most frequently. It was no original thought that some of these cases were rheumatic; clinicians, pathologists and bacteriologists had already suggested this probability, but as an actual cause of rheumatic fever had been hitherto unknown, the proof was necessarily incomplete.

Now that so much evidence had been adduced in favour of a diplococcus infection in rheumatic fever, it seemed a proper occasion to raise this question again, and to resume investigations upon it.

The result of the present research had been that the authors concluded, that *there was a group of cases of malignant endocarditis rheumatic in origin.*

The chief reasons upon which they relied for support of their assertion were summarised thus:—

First: The probability that some of these cases are rheumatic was in accord with clinical experience. The clinical cases recorded in the paper bore out this statement.

Secondly: The probability that some of these cases are rheumatic was in accord with pathological experience. The minute investigation of the morbid anatomy of the clinical cases they recorded supported this.

Thirdly: The probability that some of these cases

are rheumatic was in their opinion in accord with bacteriological experience, for

1. A diplococcus is a cause of rheumatic fever. The evidence in favour of this they had already dealt with in a series of papers published during the last two years.

2. A diplococcus can be isolated from these cases of malignant endocarditis, which will reproduce the disease in rabbits, and can be studied in pure culture.

3. The cultural and morphological characteristics of these two diplococci resemble one another so closely as to lead to the conclusion that they are identical organisms.

4. The diplococcus rheumaticus when passed through a series of rabbits will produce malignant endocarditis, indistinguishable from that produced by the diplococcus isolated from certain cases of malignant endocarditis in man.

5. The diplococcus rheumaticus may produce in a rabbit, first a recoverable illness with the manifestations of rheumatic fever, and then, on a second inoculation, malignant endocarditis.

6. A diplococcus isolated from certain cases of malignant endocarditis in man, will also produce not only malignant endocarditis in rabbits, but a condition indistinguishable from the disease we believe to be rheumatic fever.

7. By these diplococci every grade of valvulitis from simple to malignant and *vice versa* can be produced, as the microscopic specimens bore witness.

The investigation upon which these statements rested was next described in three parts: the first dealt with the clinical, experimental and pathological observations; the second dealt with the histology, and the third with the bacteriological details.

The clinical cases, six in number, exemplified the characteristic type of the disease under consideration and also the gradations between this type and rheumatic fever.

THE CLINICAL CASES.

CASE I.—A child, *æt.* 11, was admitted to St. Mary's Hospital, under the care of Dr. W. B. Cheadle, upon October 22nd, 1897, and died November 12th. When three and a-half years of age he had suffered from rheumatic fever, and when five and a-half from scarlet fever. His mother had suffered from rheumatic fever. Five weeks before admission there had been swelling of the knees and ankles, and for five months there had been complaints of obscure pains in the chest and abdomen. There was no history of an injury, no suppurating focus, and no obvious cause which could be looked upon as an explanation of some secondary infection. Upon admission the boy was very anæmic, the temperature was 100.8°, pulse 100, respiration 28. The heart was much enlarged, there was a loud systolic mitral murmur, and an aortic systolic murmur. The liver and spleen were enlarged, the urine was natural. Soon after admission crepitations were heard at the base of the left lung posteriorly, and there was pain in the left side.

(a) Abstract of a paper read before the Royal Medico-Chirurgical Society of London, April 8th, 1902.

Upon October 28th blood and albumin were found in the urine, and until death, upon November 12th, there was irregular pyrexia. Hæmaturia became persistent, and casts were found in the urine. There was pain over the spleen, and progressive enlargement of that organ. Purpura, vomiting, progressive anæmia, emaciation and sweating were prominent symptoms, and finally the pulse became irregular and intermittent, and death resulted from cardiac failure.

The necropsy showed recent pericarditis, with two ounces of fluid in the pericardium, which contained a few flakes. There was extensive ulceration of both flaps of the mitral valve, and exuberant granulations spread over the surface of the auricle. The valves upon the right side of the heart were not affected; the heart itself was hypertrophied and dilated. There were numerous white infarcts in the spleen, with perisplenitis; it was soft and weighed five ounces. There were numerous white infarcts in the kidneys, but none in the lungs. Numerous subserous hæmorrhages were visible along the intestines. There were no abscesses, but many white infarcts, as already stated. Numerous micrococci were found in the granulations.

CASE II.—The next case was that of a woman, æt. 50, who was admitted to St. Mary's Hospital, under Dr. W. B. Cheadle, in June, 1898, for dyspnoea of some months' duration. The only cause that was given for this dyspnoea was an attack of rheumatic fever eight years previously. Upon admission she was cyanosed and short of breath, and complained of pain in the left side. There was orthopnoea. The temperature was 102.8°, pulse 103, respiration 40. The heart was much enlarged, and there was a mitral systolic murmur. The hands were deformed by previous attacks of rheumatism. The nature of the case remained quite in doubt, though towards the end irregular pyrexia, infarctions in the lungs and spleen, and purpura suggested the diagnosis of malignant endocarditis.

The necropsy showed recent pericarditis, adhesive in type, and also old adhesions, the result of a previous attack.

The mitral, tricuspid, and aortic valves showed extensive vegetative endocarditis, and there were vegetations over the surface of the left auricle. There were white infarcts in the lungs and spleen, but none in the kidneys. There was no suppuration. Numerous micrococci were visible in the granulations.

The necropsy disclosed malignant endocarditis of the characteristic type, yet clinically this case was most obscure, and resembled at first a severe rheumatic morbus cordis. It was not until the end of the illness that the malignant character of the disease became apparent.

CASE III.—A patient, æt. 16, was admitted into St. Mary's Hospital in January, 1900, under Dr. Lees, suffering from morbus cordis. When six years of age he had an attack of rheumatic fever, and since that time had suffered from three more definite attacks. His mother had suffered from rheumatic fever. The final illness had commenced insidiously, with pain round the heart, and three weeks before admission there had been pains in the ankles and knees. No cause was assigned for this illness, and on special inquiry of the mother she volunteered that she had thought this was another attack of rheumatism, because it commenced just as the previous attacks had done.

On admission the patient was very anæmic and wasted, and there was irregular pyrexia, with well-marked mitral and probably aortic disease.

The course of the illness was progressive and malignant in type. Irregular fever, enlargement of the spleen and hæmaturia, with progressive anæmia and emaciation, were the prominent symptoms, and throughout the time that the patient was in the hospital no doubt was entertained as to the nature of the illness.

The necropsy showed a few ounces of clear fluid in the pericardium; the mitral valve was fringed with numerous minute vegetations, varying in size from a pin's head to a pea. There were recent vegetations upon the aortic valve, but the right side of the heart was unaffected. In the spleen there were three white infarcts, and in the left kidney one. There was no suppuration.

This case was, in one respect, the converse of the preceding. The clinical diagnosis was quite definite, but the post-mortem showed a condition which, without the clinical history for a guide, could have been explained as active rheumatic morbus cordis, and not as malignant endocarditis.

The authors investigated the bacteriology of this case, and at first included it (the resemblance was so striking) among their first series of cases of rheumatic fever published in the *Lancet* in September, 1900, but they finally concluded that it was better to rigidly exclude a border-line case of this kind, and had not made allusion to it until the present paper.

CASE IV.—This fourth case, although a case of rheumatic fever, resembled malignant endocarditis in this respect, that during life upon two occasions diplococci growing in chains were isolated from the blood. The patient was under the care of Dr. D. B. Lees, and the case was published in full in the *Lancet*, October 28th, 1899, and was the first in which they isolated the diplococcus of rheumatic fever from the blood. They naturally thought at that time that the case was one of malignant septic endocarditis, because they isolated streptococci from the blood during life, though previous investigations had made them somewhat doubtful of the validity of this conclusion. The clinical history, the course and character of the disease, and the result of the necropsy proved conclusively that it was a case of severe rheumatic fever. Though a most severe case of rheumatic fever with numerous and severe local lesions there was no suppuration, and yet during life there was a streptococcus, or, to be more exact, a diplococcus which grew in chains, circulating in the blood-stream.

CASE V.—A boy, æt. 10, was admitted to St. Mary's Hospital in April, 1900, for heart disease, under the care of Dr. W. B. Cheadle. Six weeks before admission he had suffered from pain over the heart, sweating, and attacks of diarrhoea. A year previous to this he had been in the hospital for an attack of rheumatic fever, and one brother had also suffered from rheumatic fever. On admission aortic and mitral valvulitis were discovered, and a very noticeable feature was extensive muscular wasting.

Upon April 30th he developed pericarditis.

In May there was arthritis, the ankles and knees being affected. There was also diarrhoea and vomiting. In June crepitations were detected in the lungs. In July infarction, sweating and wasting were prominent, and death occurred in July, after eighty-eight days of irregular pyrexia.

This appeared during life to be a classical case of rheumatic malignant endocarditis.

There was unfortunately no opportunity of obtaining a complete necropsy, but the heart was removed, and the pericardium was found generally adherent. The heart itself was very little enlarged, but upon the mitral and aortic valves and on the wall of the left auricle there were extensive and exuberant granulations. The right side was not affected. Films showed minute diplococci in chains. Aerobic cultures in the milk medium were obtained and transferred to blood-agar. A series of important experimental results followed.

CASE VI.—A boy, æt. 13, was admitted into St. Mary's Hospital November, 1900, for morbus cordis, under the care of Dr. D. B. Lees. Six years before he had suffered from enteric fever, and three years before from pneumonia and rheumatic fever. He had been ailing for two months previous to admission, and had suffered from pains in the chest and abdomen. The boy was pale and sallow, but well nourished; there was disease of the mitral and aortic valves, and an enlarged spleen. He remained in the hospital until his death in January, and during that time there was usually irregular pyrexia, though sometimes for days the temperature remained normal. Death was sudden.

The necropsy showed general pericardial adhesion, and fungating masses of vegetation upon the mitral and aortic valves. There were petechiæ under the capsule of the liver. The spleen weighed fifteen ounces, was tough in consistence, and contained one recent infarct.

There were numerous small hæmorrhages in the cortices of both kidneys. There was no suppuration. Two hours after death the mitral valve was exposed, and four tubes of the acid milk medium inoculated with fragments of the granulations. In two out of four there was a pure growth of very small diplococci growing in chains.

THE EXPERIMENTAL INVESTIGATION.

The experimental investigation illustrated the reproduction of the disease in rabbits and the transition to rheumatic fever. The converse, namely, the production of malignant endocarditis with the diplococcus rheumaticus, was also illustrated by the results of an inoculation with a virulent culture of that organism.

By experiment it was also demonstrated that after recovery from a first inoculation with the diplococcus rheumaticus a second inoculation might produce malignant endocarditis. Finally, investigations with the "*streptococcus pyogenes*" were described, which illustrated how widely the condition of septicæmia that can be produced by this organism differed from the usual experimental results with the diplococcus rheumaticus, isolated from cases of rheumatic fever.

They pointed out that the production of malignant valvulitis in animals without previous injury to the cardiac valves confirmed the previous investigations of Dreschfeld, Ribbert, Bonomé, Roux and Manna-berg. The occurrence of infarction and hæmorrhages was also in accord with the observations of previous investigators. The diplococcus with which the experimental results upon malignant endocarditis had been obtained, had been isolated from Cases V. and VI.

A microscopic series of preparations illustrating the transition from malignant endocarditis to rheumatic fever and the converse, was shown to the Society, and the photographs of three of the preparations, illustrating cardinal facts in the investigations, are reproduced below,

No. I. shows the reproduction of malignant endocarditis by inoculation from Case No. V.

No. II. shows pericarditis (fibrino-plastic) produced by an inoculation from Case No. VI.

No. III. shows mitral endocarditis of the malignant type produced by the diplococcus of rheumatic fever isolated from the blood of a patient during life. The organism had been passed through a series of rabbits.

FIG. I.—Malignant endocarditis (mitral valve) produced by intravenous inoculation into a rabbit of a diplococcus isolated from the mitral valve of Case V. recorded in the paper.

HISTOLOGY.

As a result of their investigations on the morbid anatomy they believed that the great distinction between a characteristic malignant endocarditis of the type under consideration and rheumatic fever lay in the relation of the diplococci to the vegeta-

tions in the valves. In the former they were present in great numbers; in the latter they were destroyed or present in scanty numbers in that part of the lesion which was not necrotic. This point was illustrated by microscopic sections. Damaged valves predisposed, they thought, to the malignant type, not because the organisms had an affinity for damaged tissues, but because these damaged tissues when attacked were less resistant than healthy ones. Just as there were all clinical gradations between the two diseases, so also there was every gradation in the character of the vegetations. In some cases of rheumatic fever there were numerous diplococci on the valves, in some cases of malignant endocarditis most of the diplococci were destroyed in the vegetation.

FIG. II.—Rheumatic pericarditis produced by the diplococcus from a Case (No. VI.) of malignant endocarditis. The parietal pericardium is reflected (A). Over the front of the heart is a layer of plastic exudation.

FIG. III.—Malignant endocarditis (mitral valve) produced by intravenous inoculation of the diplococcus of rheumatic fever into a rabbit.

BACTERIOLOGY.

The chief bacteriological differences between the two diplococci were, so far as they had ascertained, that the diplococcus from the malignant cases was more minute and grew in larger chains in fluid media, and in larger masses on solid media. Such differences they believed could be explained by the greater vigour and more rapid growth of the organisms.

In other respects they were similar in their behaviour.

Both diplococci were acid-producing, and Dr. Sidney Martin, when investigating ulcerative endocarditis, had attributed the production of acid by such micro-organisms to a non-proteid substance formed by their growth.

There appeared to be a strong leaning to the view

that, in rheumatic affections there must be some acid-producing process, and the value of alkalis in the treatment of these affections was widely accepted. Might not the explanation of their value possibly lie in the acid-producing property of these bacteria? Might not also a gouty attack in a gouty person be in some cases a result of infection with such acid-producing micro-organisms, and thus a link in the mysterious association of gout and rheumatism be made evident?

CONCLUDING OBSERVATIONS.

The concluding part of the paper was concerned with observations upon rheumatic, rheumatoid and septic infections.

The first question that arose was this one: Is rheumatic fever a specific disease or the outcome of many and varied infections? If it be a specific disease the problem arose as to how much this specific nature was dependent on the poisons formed by the micro-organism, and how much on the peculiar tissue reactions, and in this problem lay the explanation of the origin of the malignant type of the disease.

Many held, with Singer, that neither was rheumatic fever a specific disease, nor the infection the result of any one micro-organism, but that rheumatic fever might result from infection with any of the attenuated pyogenic cocci. The authors claimed that the onus of proof lay with those who upheld this view. They themselves had only found one cause—a diplococcus—and were of opinion that no other organism had as yet been demonstrated in all the local lesions, both in man and animals. Other micro-organisms might have been isolated, but had the disease been reproduced by these other organisms?

But if, eventually, other micro-organisms were found to be causes of the disease, it did not alter the fact that the diplococcus was one cause, and it was important to ascertain the relation of the diplococcus to others in the great group of pathogenic micrococci. The fact that it grew in chains in liquid media brought it into the streptococcal group (the same applied to the diplococcus of pneumonia), and the natural suggestion would be that it was the attenuated streptococcus pyogenes.

The authors were, however, doubtful whether attenuation could be used in this sense—rheumatic fever possessed many peculiar characters—and, again, they had not been able to produce pyæmia with the diplococcus of rheumatic fever, or rheumatic fever with the streptococcus pyogenes. It was admitted by all, however, that the complete separation of the various members of the streptococcal group was as yet not possible; further research was needed. The differentiation of these micro-organisms was closely bound up with the great clinical problem as to whether rheumatic and septic processes were essentially different, or merged into one another. Dr. Poynton and Dr. Paine, for the purposes of investigation, arranged these two processes in the following manner:

Mild rheumatic fever.	Mild pyæmia.
Virulent rheumatic fever.	Virulent pyæmia.
Malignant rheumatic endocarditis.	Malignant septic endocarditis, with abscess formation (?)
Some cases of cerebral rheumatism (?)	Acute septiciæmia.

This was only provisional, and in order to have some definite working basis.

They thought that the persistent local processes which characterised malignant rheumatic endocarditis, were sometimes also met with in the pericardium and the joints in rheumatic fever, though it was clear that it could only be with lesions of car-

diac valves or the large blood vessels that the micro-organisms could be brought into such close contact with the general circulation.

They had recently isolated, demonstrated in the synovial membrane, and cultivated, a diplococcus, morphologically identical, from a case of rheumatoid arthritis, and produced arthritis and osteo-arthritis in rabbits as a result of intravenous inoculation. It was, then, highly probable that some cases of rheumatoid arthritis were in reality examples of malignant rheumatic arthritis.

In conclusion, they expressed their hearty thanks to Dr. W. B. Cheadle and to Dr. D. B. Lees for the use of their cases, and to Mr. H. G. Plimmer for assistance and advice.

PERFORATED GASTRIC ULCER (a).

By R. F. TOBIN, F.R.C.S.,

Surgeon to St. Vincent's Hospital.

PERFORATED gastric ulcer is such a growing subject and one of so much interest to both physician and surgeon that I shall make no apology for venturing to introduce it for discussion, by laying before you some particulars of and remarks upon the four cases referred to in the agenda-paper. The rate at which the subject is growing I would indicate by quoting the concluding remarks of a remarkable paper read by Dr. Parsons before this Section in 1892. In it, he says, "if I have persuaded any of my audience to add acute peritonitis to the generally admitted four great surgical emergencies requiring immediate operative interference, my object in writing this paper is gained." These remarks were very fitting then. Surely there is no one here to-day to whom he could address them—his object has been completely gained.

The four cases I am about to refer to were all in St. Vincent's together at the beginning of this academic year, and I opened the Session with a clinical lecture on them. Three of them had been operated on by me, the fourth by my colleague Dr. Alfred Smith, at whose request I have incorporated it with mine, first because it has much in common, secondly because he refuses to have anything to do with it. "I never," says he, "travel beyond my own area except on compulsion."

The following are points of resemblance in these cases. All were women between the ages of twenty and thirty, and of that weak texture that marks anæmic girls. All had previously complained of gastric trouble; three of the four were domestic servants. In all the situation of the ulcer was the same, in all there was a similarity of symptoms, in all the method of operation was, excepting one or two details, identical, in all there was not only recovery but a more rapid return to good condition than would probably have been the case had they been admitted to hospital just before the perforation had occurred and had that catastrophe been averted by rest and medical treatment. The symptoms in the four cases at the time of operation also showed much uniformity. There was pain in the left epigastric region and pain above the left clavicle, scanty vomiting and retching, rigid abdomen, absence of abdominal respiration, absence or diminution of liver dullness, and shock.

Let me refer in detail to some of these points.

1. The position of the ulcer: They were all situated as in the specimens I show you from the Museum, R.C.S.I., at a point an inch or two in front of the oesophageal opening. This, as far as I can judge from my own observations, records of cases, verbal communications and specimens in museums,

(a) A paper read before the Medical Section of the Royal Academy of Medicine in Ireland.

seems to be far and away the most common site for the operating surgeon to find a perforation. Granted that this is so, the interesting question arises, Why is it? My explanation, not of the ulceration but of the perforation that accompanies ulceration

in this locality, is as follows:—The perforation, as I have just said, occurs in the area of the stomach that extends forward from the esophagus underneath the liver, an area that would be pressed upon by the liver were that organ unduly depressed or the stomach unduly drawn up. Now, owing to the laxity of tissue in the usual sufferers from this disease, and to the fact that they are on their legs all day long, the liver is not well braced up. Moreover, the stomach, owing to its fixity to the diaphragm is being continually drawn through a long range of movement as the anæmic sufferer goes about her work. Now, thinking of these conditions and how they are likely to act on the tissues of the area under consideration when they have become congested, infiltrated, and lost their elasticity—considering these things, I wonder not how congestion goes on to ulceration and ulceration to sloughing, but how it is that without rest these patients ever recover. And at the same time I understand, a fact with which we are all acquainted, the healing power of rest in the treatment of such cases.

The next point I would refer to is the early, the very early disappearance of liver dullness in the mesial line. This earliness is, I think, diagnostic of anterior perforation; I never opened or was present at the opening of an abdomen in a case where there was an anterior perforation without noticing an escape of gas. Gas in that locality must lead to diminution of resonance, and it is but right to suppose that most of such gas escaped at the moment of perforation.

The third point I wish to emphasise has reference to shock; how greatly shock is increased by movement.

One of the cases of which I am speaking was sent to me by Dr. Kennedy. He saw the case almost immediately after the occurrence of the perforation. Shock was not then very pronounced, but it became profound, as no doubt he will tell you, during the short transit to hospital. I met the case in the hall of the hospital on arrival and had her taken straight to the operating theatre, and when on exposing the perforation we saw how at every turn and cough and attempt to vomit the stomach contents welled up or welled out, the inadvisability of moving such cases was strongly borne in upon us. Dr. Kennedy did what has been the rule in such cases. The surroundings of the patient banished the idea of operating where he found her, but he tells me that, having seen the case from start to finish, notwithstanding that she recovered, he would not again move such a case till the opening had been closed. In contrast with this case as regards shock was one I saw in consultation with Dr. Price at Graystones. On getting out of the train at that station one evening in August

last I found Dr. Price waiting for me on the platform. He told me that the maid-servant of a gentleman in Greystones had sustained a perforation of the stomach that forenoon, and he wished me to see her. We went to her in company with Dr. Keegan, who happened to be on the platform. The perforation was readily found and closed, although I had with me only the simplest appliances, and the patient made a good recovery. In this case the perforation was larger than in the case already referred to, and the contents of the stomach about the same, but owing to her having been kept perfectly quiet the collapse was not profound.

From the considerations laid before you I would deduce the following rules for guidance:—

In cases of perforation of the stomach the patient should be moved as little as possible till after the suturing of the perforation. A perforation in the stomach—I would say in any intestine were it within the limits of my subject—should be treated like a perforation in a blood vessel, *i.e.*, cut down upon and closed *at once*. The surgeon should go to the patient, not the patient to the surgeon. The conveniences of an operating room are not worth the certain loss incurred by transit, for with care and thought asepsis can be secured anywhere. To take a concrete case. If I were called to a kitchen to a servant who had got perforation, I would have her carefully lifted on to the kitchen table, and I would there and then seek the perforation, and if possible, close it. The operation is, as a rule, an easy one. The necessary appliances very few. A knife, a forceps, a needle and thread, water, towels, handkerchiefs, and rags made aseptic by boiling. A two-inch incision, under cocaine if preferred, will in most cases, make matters clear. If it does not, what harm has been done?

I know of only two arguments that are urged against this immediate procedure. First, that the perforation may be so situated as to make its closure a matter of great difficulty. To this I say that such cases are the exception, and it is for the general case one makes the rule. Moreover, I can scarcely imagine a case for which something could not be done. No one has done much work with the stomach without learning that the crudest closing of an opening as long as the peritoneal surfaces are brought together gives good results. As far as my knowledge goes I would sooner close a perforation with a small clamp or catch forceps and leave it *in situ*, to be removed later on, than send a patient on a journey to hospital with gastric contents escaping at every jolt. Secondly, that it is often well to let the patient recover from shock, and with that end in view she is ill-placed on, say, a kitchen table.

My answer to this objection is that you should not wait for the disappearance of shock. What is the cause of shock in these cases? It is the escape of the gastric contents into the peritoneal cavity. It is in proportion to the amount that has escaped. Now, if you pause, should the patient cough or vomit more will escape. Moreover, these are not instances of mere nervous shock, where nothing harmful is going on while you wait for the patient to come round. On the contrary, processes of the greatest moment are in progress, changes that may end in thrombosis of the mesenteric veins and render recovery impossible. I say, therefore, to the physician, call the surgeon at once to the patient; and to the surgeon, operate as soon as you can; get ready even the simplest appliances.

One word in conclusion as to the prevention of gastric perforations. If I have correctly stated the causation this is surely to be found in recumbent rest. In the ward of mine in which the patients of whom I have been speaking were

lying at the beginning of this session there were other beds, and in these beds were elderly domestics with chronic ulcers on their legs. Both the young domestics and the old domestics were, as I pointed out to my class, the subjects of ailments that quadrupeds never suffer from, and that bipeds who take proper rest do but rarely. Surely, therefore, in rest, and in rest in the recumbent position when possible, is to be found the prevention of such ailments. But the domestic servant who is the first of the household to get up, and often the last to go to bed, is invariably left during her long waiting hours with no means of lying down or even of reclining, however weary she may be. Is this right?

To what waste of force and to how many other ills in addition to those I have named does it not give rise? It is out of the question going further into this subject at the conclusion of a brief paper such as this. Suffice it to say that the climate and conditions under which we live, the crowding in buildings for the purposes of shelter, in vehicles for the purpose of transit, the coldness of the ground preventing the easy eastern solution of the question, the stress of competition, have made us forget in a great measure as regards our own persons, altogether as regards the persons of those committed to our care, what is the most essential condition in taking rest. How many of us day by day tell the servants who come to us with chronic ulcers of the stomach or of the legs to rest as much as possible, at the same time knowing well that during the intervals of their work there is in most houses, short of going to bed, no means of their properly carrying out the suggestion that we offer?

IDIOPATHIC OR CONGENITAL HEREDITARY AND FAMILY HÆMATURIA.(a)

By LEONARD G. GUTHRIE. M.D.Oxon.,
F.R.C.P. Lond.

Senior Physician, Paddington Green Children's Hospital;
Physician, Hospital for Epilepsy and Paralysis, Regent's Park.

IDIOPATHIC hæmaturia is not mentioned as such in text-books, nor have I found any reference to it in medical literature. Dr. W. H. Atlee has, however, recorded "Three Cases of Recurrent Hæmaturia occurring in One Family" (*St. Bart's Hosp. J.*, Dec., 1901), which I believe to be of the same nature as those which form the subject of this paper. The "Essential Renal Hæmaturia" of Debairieux (b), in which hæmorrhage occurs from apparently healthy kidneys, is doubtless closely related to idiopathic hæmaturia, but lacks the hereditary, congenital, and familial characters of the latter complaint. (c)

I have knowledge of the existence of idiopathic hæmaturia in twelve persons. Eight of these are brothers and sisters or first cousins; their mothers are two sisters, who are themselves subject to this complaint. These sisters had two brothers, both of whom were similarly affected. The complaint is therefore familial and hereditary, but at present has only descended to the second generation. It is impossible yet to say whether it may or may not be further transmitted. Seven of those affected have been females, and five males. So far as my own cases are concerned, hæmaturia has only been inherited through the maternal side, but Dr. Atlee's cases (to which further reference will be made) suggest that it may also be inherited from the male parent.

In all my cases it appears to be congenital, or has been noticed shortly after birth.

The first generation of the two families mentioned consisted of two brothers and three sisters, all of whom, except one sister, had been liable to hæmaturia from birth. The two brothers died between twenty and thirty years ago, æt. 4½ and 11 respectively. The exact cause of their deaths cannot be ascertained. Two of the sisters affected are now æt. 40 and 30, are married and have issue. The elder has seven children, of whom four girls, æt. 18, 15, 13, and 10, and one boy, æt. 6, are subject to hæmaturia, whilst one girl and one boy escape. The younger sister has two boys, æt. 8 and 3, and one girl, æt. 11, all of whom are affected.

The third sister, who is free from the complaint, is unmarried.

The eldest daughter of the elder married sister suffers from eczema and spasmodic asthma as well as from hæmaturia. The third daughter has had attacks of epistaxis and hæmatemesis but no hæmaturia. Gout and rheumatism are said to exist on the maternal side of these families, but no other family complaint.

I have personal acquaintance with only three members of the families, namely, with the elder married sister and with her second daughter and youngest boy.

The characteristics of idiopathic hæmaturia may thus be summarised:—

1. It is hereditary, familial, and congenital.

2. The hæmaturia may be persistent for many years, but vary in extent. In some cases it may cease for a time, but in all it is apt to recur, or to increase, in paroxysmal attacks, or exacerbations.

For instance, in one of my cases the urine examined almost weekly for upwards of two years has never failed to contain blood visible to the naked eye, and to give a marked reaction with ozonic ether and guaiacum. Its colour varies from that of old gold tinged with red to the bright scarlet of oxyhæmoglobin.

In another, blood is always present, but can only be detected on microscopical examination, except when exacerbations occur. At these times the urine may resemble almost pure arterial blood. It is not "smoky" in appearance but "red," the colour being due to oxyhæmoglobin not methhæmoglobin.

Normal red blood corpuscles and blood casts can always be found under the microscope, so the colour is not due to hæmoglobinuria. The blood casts show that the hæmorrhage is from the substance and not from the pelvis of the kidney. The amount of blood passed during exacerbations is always far greater than is ever seen in cases of nephritis, and resembles in its profuseness the blood passed in cases of renal calculus or new growth.

3. All cases are liable to paroxysmal exacerbations of hæmaturia, which are usually accompanied by slight pyrexia, malaise, headache, vomiting and slight pains in the back or limbs. The exacerbations are often attributed to "catching cold," and are associated with slight bronchial catarrh, or with trivial ailments such as toothache, earache, or sore throat. In some cases, articles of diet, such as black currants, asparagus, strawberries, claret, and, perhaps, rhubarb have been held to produce them. But the exacerbations may occur without complications, and in the absence of special causes.

The duration of these exacerbations is usually several days, but seldom exceeds a week or at most a fortnight, and after the first few days the blood gradually lessens in amount.

They have no law of periodicity nor of frequency. They may occur at intervals of weeks, months, or years. But they appear to become less frequent after the first decade has been passed. They occur with extreme suddenness by day or by night and are not

(a) A Paper read before the Harveian Society of London, April 22nd, 1902.

(b) "Annales des Organes Genito-Urin." No. 9, 1898.

(c) Cf. also J. H. Bryant, *Clinical J.*, July 25th, 1900, p. 214.

influenced by posture. Extremes of hot or cold weather seem to give rise to them.

4. Idiopathic hæmaturia is not associated with oedema nor with ascites, nor with the cardio-vascular changes following ordinary nephritis. Except at times when exacerbations occur, the subjects appear to be, and are, in perfect health. There may be temporary anæmia after an exacerbation, but it is not profound nor lasting.

5. The hæmorrhage is not due to the presence of uric acid nor of oxalates.

A few crystals of these substances may often be found on microscopical examination, but free gravel is never passed, neither is there any excess of uric acid in solution.

The amount of urea passed is normal.

6. The specific gravity of the urine is not unduly low. It varies from 1015 to 1030. The quantity of urine passed is not above nor below normal. The reaction is acid or neutral. The urine is nearly always albuminous, the albumin varying from one-twentieth to one-fourth of its bulk. Sometimes it is in accordance with the amount of blood present, at others it exceeds it.

Nucleo-albumin is usually passed as well. The sediment nearly always contains free normal red blood corpuscles, and tubular blood casts in more or less abundance, but never hyaline casts.

Finally, none of the subjects of idiopathic hæmaturia is a "bleeder." One of them recently had some adenoid vegetations removed, and the hæmorrhage caused was neither profuse nor prolonged. None of them suffers from Raynaud's disease nor from purpura. Scarlatina can be excluded as a cause in all cases, and also calculus, new growth, congenital syphilis, renal tuberculosis, and all forms of nephritis. The kidneys are not movable, palpable, nor tender, and there is no definite nor constant local pain.

CASE I.—Peter X., now *æt.* 6, has been under observation for three years. He was nursed until nine months old, then fed on Savory and Moore's food and cow's milk. At three months of age he suffered from slight eczema of scalp and face, seemed weakly, and had occasional attacks of diarrhoea and vomiting. From the first his urine was noticed to be blood-red in colour from time to time, but this attracted little attention as it was known to be a family affection. Advice was sought chiefly because of nocturnal and diurnal enuresis and frequency of micturition.

He is a healthy-looking, ruddy, and chubby child, full of life and spirits. Heart and pulse normal; kidneys not palpable; no renal tenderness nor pain; no trace of oedema at any time.

The urine examined at weekly intervals for about two years has never been free from blood. Reaction subacid or neutral; sp. gr. 1015 to 1030. The colour varies from old reddish gold to bright blood-red. The blood is always discernible by the naked eye. The urine is never smoky in appearance, and Dr. Archibald Garrod, who kindly examined it, found that the colour was due to oxyhæmoglobin not methæmoglobin.

Uric acid is never passed as gravel, and quantitative analysis by Dr. Garrod showed it to be diminished rather than increased in solution. He estimated the total amount passed in twenty-four hours as 0.150 grm. on one occasion and 0.1629 grm. on another (Hopkin's method used); 100 cc. contained 0.0410 grm. uric acid on one occasion and 0.038 grm. on another.

The deposit usually contains a few crystals of uric acid or oxalates, many red blood corpuscles and blood casts, but no hyaline casts. The total quantity passed is not above the average.

Albumin is always present in quantities varying with the amount of blood present. The average

content of albumin is about one-twelfth. The urine almost always contains nucleo-albumin as well.

During the past three years the child has had periods lasting about a week and occurring every two or three months, in which the blood is greatly increased in amount. I have never seen him at such times, but gather from his mother's description that he has usually some slight malaise, his tongue becomes furred, and he may be restless and scream in his sleep. The exacerbations of hæmaturia are often preceded and accompanied by enuresis and frequency of micturition. They are often associated with "catching cold," or some slight ailment such as toothache or earache. After vaccination, the urine was said to improve in appearance as the arm got better. On the other hand, during an outbreak of eczema the urine was not dark until the rash was fading. Pertussis, which he had for six weeks, "did not upset him nearly as much as might be expected." Influenza increased the flow of blood.

Extremes of hot and cold weather render him more liable to attacks. The hæmaturia is not more marked in diurnal than in nocturnal urine.

The effect on his general health does not seem to be great. His mother says "his spirits never seem to fail, he is as bright and merry as possible, even when the urine is very bad." The attacks do not seem to be induced by any particular diet except by strawberries and asparagus. Black currants, which used to produce hæmaturia in his mother and in two sisters, had no effect on him. Gooseberries, raspberries, and grapes agree with him; rhubarb has never been given to him. He seems to thrive on ordinary diet.

Treatment.—Hazeline, ol. terebinthinæ, calcium chloride, ergot, gallic and sulphuric acid have been used without much effect on the hæmorrhage. The only drug which seems to cut short the attacks is substantia suprenalis in 1½ gr. doses three or four times a day. Urotropin seemed to increase frequency of micturition and incontinence, but these discomforts are speedily relieved by a few doses of tr. hyoscyami with citrate of potash and infusion of buchu.

Beyond keeping him indoors and lying down during the exacerbations, little has been done, and more seems unnecessary in the way of treatment.

CASE II.—Dora X., now *æt.* 15 (sister of above), has also been under observation for three years. The urine examined on many occasions during that time has never failed to contain blood and albumin, but as a rule the blood is less in amount than in the previous case, and there is rather more albumin.

The average amount of albumin is about one-tenth. Sometimes it falls to a one-twentieth part. Nucleo-albumin is also present. As a rule the blood can only be detected by microscopical examination, when fragments of blood casts and red blood corpuscles are found, but no hyaline nor true granular casts. The reaction is acid or neutral; the sp. gr. 1015 to 1025; free gravel is never passed, and Dr. Garrod estimated the quantity of uric acid in solution as about the same as in the previous case, 0.0412 grm. in 100 cc.

She had a typical attack or exacerbation of hæmaturia two years ago, but never since. The practitioner who then attended her kindly sent me the following particulars.

In February, 1900, she had a severe sore throat, which, however, lasted only a few days, and she then seemed well. There was no rash, and she had had scarlet fever four years previously. About a week after the throat became well the urine was noticed to be getting darker, and a night or two later she was violently sick and passed a quantity of bright scarlet urine, which was practically pure blood. The tongue was brown and dry, the tempe-

perature 102°, and she complained of headache, but of no other pain. The temperature gradually fell, and the urine regained its normal appearance in about a fortnight. There was never any trace of oedema. She is a well-grown and fairly healthy-looking girl, though slightly anæmic. The heart is normal in position, size, and sounds. The pulse tension is not unduly high. The kidneys are not palpable, nor is there any renal tenderness.

Quite recently she has had some adenoids removed. The hæmorrhage was not excessive nor prolonged, which disproves the existence of hæmophilia in this case. The hæmaturia was not affected by the operation.

She prefers butcher's meat to any other article of diet, and cannot take milk without tendency to vomiting. Black currants are said to induce major attacks of hæmaturia in her case as in other members of the family.

Of the other members of the family I can say but little. The mother of P. and D., who is now æt. about 40, states that as long as she can remember she has been subject to such attacks as her children have had, and that as a child she was always considered delicate in consequence. The attacks, she says, were always produced by black currants or by claret, but they occurred also in presence of any ordinary slight ailment. The last occasion on which severe hæmaturia occurred was six years ago, shortly after the birth of her youngest child (P.), and she says that the doctor who attended her, not knowing her previous history, was "horried to find her going about with so much albumin and blood in her urine." She has not had any further attack of hæmaturia since then. She has not complained of being out of health, as far as I know, for the last three years, and she always appears to be well, active, and energetic.

Other Cases apparently of Similar Nature.

Dr. W. H. Atlee (*St. Bartholomew's Hospital Journal*, December, 1901) gives a succinct account of "Three cases of Recurrent Hæmaturia occurring in One Family." The patients were females, æt. 5½, 4½, and 2 years and 4 months respectively, and were admitted to the Metropolitan Hospital under the care of Drs. Arthur Davies and Haig, during the year 1901. The father died, æt. 30, of uræmia. The mother seemed to be a perfectly healthy woman.

All these children were well nourished and appeared to be in perfect health. Scarlet fever could be excluded in all of them, and none exhibited any definite signs of nephritis nor of cardio-vascular changes. Calculus could be excluded, and also new growth and tuberculosis in all cases. One of them, æt. 4½, had four attacks of hæmaturia, in which the urine became bright red, between April and December, 1901. The child had been subject to epileptic fits since eleven months of age, but the hæmaturia was preceded by a fit on only one occasion.

The attacks of hæmaturia were ushered in by malaise, sometimes by pain in the legs, or by vomiting and slight pyrexia. A typical exacerbation is thus described, after a period during which the child had seemed quite well except that the urine contained a faint trace of blood:—"On December 29th, 1901, she suddenly complained of not feeling well. She had no pain and no fit. The temperature rose to 101·8°, and about six hours afterwards the urine was again bright red. The temperature kept up for two days, then became normal and continued so. The blood decreased to a mere trace, and then remained stationary." The urine was always acid and averaged 20 ounces per diem. The sp. gr. was 1026 to 1015. Albumin and blood were always present, and occasionally granular casts.

Another of these sisters, æt. 5½, was admitted to hospital on May 20th, 1901. On May 16th she complained of headache, pain in the right side of chest, and vomited three times. On admission she had slight bronchitis, the temperature was 100·6°, the urine was smoky, acid, sp. gr. 1017, contained a cloud of albumin and a considerable amount of blood, blood corpuscles and blood casts, but no crystals. After five days the temperature became normal, and remained so. The urine contained no blood after June 6th, but a trace of albumin.

In the following December the urine contained a cloud of albumin and blood, but nothing else was found under the microscope.

The third child, æt. 2 years and 4 months, vomited twice on May 31st, and again, frequently, on June 1st, when her temperature rose to 101·8°. On the evening of that day the urine was found to be scanty, loaded with albumin, and to contain much blood. The pyrexia continued until June 4th, when the temperature gradually fell to normal. The amount of blood rapidly decreased, and on June 6th there was none to be found, but a trace of albumin existed until her discharge from hospital on July 8th.

The urine was acid; sp. gr. averaged 1017. A fair quantity was always passed after June 5th. Granular and epithelial casts were passed on two occasions, but no crystals.

There can be little doubt that these cases are of the same nature as my own. It is true that evidence of the congenital tendency to hæmaturia is wanting, the youngest child being two years and four months of age when hæmaturia was first noticed. But hæmaturia may have existed long before, though in so slight a degree as to escape detection.

The amount of blood present in the urine of my second case was so small for several months after she first came under observation that I doubted whether she shared the family proclivity until the typical attack of profuse hæmaturia took place.

The fact that the father of Dr. Atlee's patients died, æt. 30, of uræmia is of significant interest. It is possible that he also suffered from idiopathic hæmaturia. If so, the prognosis in such cases must be guarded although the affection does not seem to endanger life, or even health as a general rule. It will be observed that in Dr. Atlee's patients the inheritance is from the father and not from the mother, as in my own cases.

The explanation of these mysterious cases remains to be discussed.

The fact that the hæmaturia is congenital or, at all events, noticed shortly after birth, excludes all the ordinary or known causes of such hæmorrhage.

The most reasonable supposition is that there is some inherent weakness or varicosity of the walls of the renal vessels leading to what has been called renal hæmophilia (a) or renal epistaxis (b). Or the vaso-motor system may be at fault (angio-neurosis), in which case the complaint might be grouped with cyclical or postural albuminuria. But as already mentioned the hæmaturia is in no sense postural. The exacerbations occur as often during the night, or whilst the patient is at rest in bed, as by day when he is up and about.

The diagnosis of idiopathic hæmaturia rests on the personal and family history, on the occurrence of the febrile exacerbations in which the hæmaturia far exceeds that of acute nephritis, on the absence of oedema, dropsy, and cardio-vascular changes, and, finally, on the absence of any of the well-known causes of hæmaturia.

(a) Senator, Broca, Fasset.

(b) Hurry Fenwick has found varicosity of the papillary plexus in cases of painless unilateral hæmaturia in young adults, and has cured them by papillectomy (*Brit. Med. Journ.*, Vol. I., 1900, p. 28).

Clinical Records.

CASE OF RECURRENT HÆMORRHAGE AFTER MOLAR ABORTION; SYMPTOMS SIMULATING THOSE OF DECIDUOMA MALIGNUM. (a)

By H. MACNAUGHTON-JONES, M.D., &c.

DR. MACNAUGHTON-JONES said that these short notes of a case that came under his observation showed the difficulty of diagnosis, as well as prognosis, in certain forms of prolonged discharge associated with molar pregnancy. He read them as bearing upon the paper of the President, Dr. Halliday Croom, on "Deciduoma Malignum."

A lady, æt. 23, consulted me in August, 1899. She had been married one year and eight months. When I saw her her symptoms were mainly persistent sickness with aggravated pains in the hypogastrium. She also complained of pain in the right groin and down the corresponding thigh. From her physician I had the following history:—She had been a delicate child, anæmic, and with marked lateral curvature, and at one time consolidation of the apices of both lungs. During adolescence she suffered from severe dysmenorrhœa, which was accounted for (through an examination under anæsthesia) by the presence of a conical cervix with very contracted os and marked retroflexion of the uterus, the ovaries, however, being normal in size and position. The uterine canal was dilated, and the uterus straightened and re-posed. Sufficient relief not following, later on the uterus was dilated and curetted, very little retroflexion remaining, and the dysmenorrhœa practically ceasing. Some time after marriage a metrorrhagic discharge commenced. She described it herself as "a brown discharge" which always began a few days after her period, lasting until the commencement of the next. She was greatly reduced in weight, and anæmic.

When I saw her I found on examination, at her first visit, that her uterus was enlarged, the cervix soft; a cervical laceration and a slight erosion present, with some sanious discharge; as she had passed over a period I did not measure the uterine cavity. That evening severe hæmorrhage occurred, which increased the next day, when she again came to me. On now examining I found a molar mass protruding from the os. The following day I dilated the uterus, curetted it, as I thought thoroughly, and applied chromic acid. I removed a quantity of molar debris. There was some foetor. I could not discover any chorionic remains on floating the substance in water. After the application of chromic acid, an iodoform tampon was inserted. This was removed after forty-eight hours, and the patient was doing well when on the fifth day some severe bleeding occurred, and on examination I found a substance filling the cervix. I accordingly quickly dilated it, and with a small ovum forceps brought away a mass which evidently had remained after the curetting. This was very foetid. The curetted debris was submitted for examination, and a report furnished by Mr. Targett that it consisted of products of gestation. The cavity of the uterus at the time was nearly four inches in length. On a few subsequent occasions I wiped out the uterine cavity with ichthyol and iodised phenol. She did perfectly well until October, 1899, when, as there was a recurrence of some hæmorrhage, I again dilated the uterus, curetted it, and applied chromic acid. There was nothing of any pathological importance in the curettings.

(a) Read before the British Gynæcological Association, April 10th,

The following August, a year from the date of the first operation, bleeding and pain again commenced, with some sensitiveness of the uterus on examination. Also there was a recurrence of the erosion in the neighbourhood of the old laceration, while a small fungoid-looking growth protruded from the lip of the os uteri. I determined to curette her again, thoroughly to remove the growth, and excise the laceration. I was now very uneasy about the nature of her disease, and had the fear of deciduoma unpleasantly before me, so much so, that I asked Mr. Targett to be present at the operation and see the condition, also to make a careful examination of the tissue removed, determining to perform hysterectomy if it proved to be of a malignant nature. I was relieved to find that this was fortunately not so. There was no further bleeding. I again wiped out the uterus a month later with iodised phenol, and she left England at the end of 1900 perfectly well. When last I heard from her, in October, 1901, she reported that though she had gained twenty-eight pounds in weight, and had felt very well, she had had a recurrence of her old symptoms and characteristic discharge. This had ceased for some time before writing. Here was a case which, from the point of view of age, pregnancy, molar degeneration, and the suspicious signs, I should not be surprised if deciduoma or sarcoma did eventually result.

ROTUNDA HOSPITAL.

A Case of Puerperal Aphasia.

Under the Care of R. D. PUREFOY, M.D., F.R.C.S.,
Master of the Hospital.

THIS rare and interesting condition was well illustrated in the case of R. F., æt. 33, 1-para, healthy appearance, who was admitted on the 9th and discharged on the 16th of April. Her history was as follows:—Her pregnancy had proceeded most favourably till the beginning of the ninth month, at which time her husband one day, on his return from work, found her in bed, and unable to speak anything but the word "yes." At the same time he observed large quantities of vomit on the floor. Her labour was uneventful, and during the puerperium the following observations were made:—

Nervous System.—Cranial Nerves.—1st. Olfactory sense apparently normal. 2nd. Optic discs normal; vision normal. 3rd, 4th, 6th. Ocular movements good and equal in all directions; pupils react to light and accommodation; no nystagmus. 7th. Facial movements normal. 5th. No sensory changes; taste normal. 8th. Hearing normal. 9th. Palate, nil; swallowing unimpaired. 10th, 11th and 12th. Nil.

Mental Condition.—Slight mental hebetude; receptive power slightly impaired; understands what is said to her, but after a slight interval; performs required actions after an interval. Writing power is fairly good; most of her letters well formed, but at the end of a word the letters are not so well formed as at the beginning. Memory is apparently unimpaired, as she is able to write down her age and where she lives, although when asked to speak the answers she was unable to do so. A few days after delivery she became able to say some words, as "yes," "no," "third," "I don't know;" but as often as not she would answer "yes" when she should have said "no," &c.

Motor Power is good in legs and arms; no paralysis detected; sensory nerves; no anæsthesia, nor analgesia; thermal sense normal.

Reflexes.—All normal.

Sphincters.—Has had no incontinence of fæces or urine since admission, and the patient apparently always knew when there was need for the performance of either function.

Arteries.—No thickening nor tortuosity detected.

Heart.—Sounds clear in all areas; apex beat normal in position.

Before going out the patient was able to repeat her prayers, &c., fairly correctly. The words she uses are correctly said; there is no slurring nor misplacement of syllables. Patient could read written questions, and write the answers fairly correctly as regards spelling, but often wrong as regards sense.

Owing to the kind exertions of my friend Dr. Wilson, who recently resided some months in the hospital, I am in a position to supplement this most important history with the following details relative to the woman's present state of health:—

On examination, ten months after being in hospital, patient states that four months elapsed before she recovered comparative freedom of speech, but it has gradually improved. No defect is apparent in the cranial nerves.

Mental Condition.—Mental action is slower than normal.

1. She understands all that is said to her, in accordance with her education.

2. She has the power of recognising uses and relations of objects—i.e., no aphasia.

3. She had the power to recall names of familiar objects seen, tasted, heard, or touched, or smelled, though she is unable to tell the names of unfamiliar objects, although she may know in her own mind what the name is, and if pronounced by another she at once recognises it, and can say if it is properly pronounced.

4. She can understand printed or written language.

5. Understanding of musical tones is somewhat deficient (perhaps normally so).

6. She has the power of voluntary speech, and there is no misplacement of words.

7. She can read aloud, but not so well as she could do before her illness.

8. Patient has lost the power of voluntary writing, except a few words, such as her name and address, and the name of her child. She is not able to voluntarily pen a letter, though she knows what she wishes to say (agraphia). Her husband does her correspondence.

9. Patient is quite able to copy correctly from writing or print. She gets her husband to write what she dictates to him, and then she can easily copy it, and write the letter.

10. She can write to dictation, only very short and simple sentences. Each word must be repeated separately before she can write it, and even then she spells words wrongly. When the correct spelling is shown she can at once detect her error. She is very slow and takes a long time to consider how to write a word after hearing it, but in copying from print there is very little delay.

11. Power of repeating words is limited to those with which she is familiar; long words she mispronounces, and knows that she does so; strange words she cannot pronounce at all until pronounced clearly and very often before her. No motor paralysis, no anæsthesia, or analgesia; thermal sense normal, as also reflexes.

Patient's Statement.—Says she is all right; has some difficulty in explaining uncommon occurrences; was unable to do any shopping for the first five months; she knew the names of the things she wanted, but could not say them; is slow in counting money; can manage all the household duties perfectly well. After any prolonged mental work she says that she feels confused, and fails to understand things clearly. It was noticed that towards the end of the examination she confessed that she was tired thinking.

Another case was that of a patient admitted to

the hospital three years ago, suffering at that time from impaired power of speech and locomotion, and I think it of interest to recall it now as affording several points of contrast with the two recently under observation. Mrs. S., æt. 35, when in the sixth month of her third pregnancy began to suffer from gradually increasing impairment and difficulty in speech and locomotion, for which she could assign no cause. These troubles increased, and were observable plainly at the time of her admission to hospital. Her labour ended in the birth of twins, unaided, and the convalescence was satisfactory, but not followed by any improvement in the points mentioned. She is now living in the country, and has given birth to another healthy infant. Her power of walking is so diminished that she is unable to leave her house, and her speech has the same halting character which first attracted my attention. Neither in the beginning of these troubles nor since has she suffered from headache or vomiting. Her articulation and choice of words are good, but she speaks, as she moves, with slowness and hesitancy.

In the case of A. O'T., æt. 34, admitted to hospital December 7th, 1900, we have another example. When about seven months pregnant, and suffering from much fatigue and anxiety caused by the illness of her children, she became suddenly affected with impairment of speech, some confusion of ideas, and lessened ability for her ordinary work. To these troubles were added pain in the occiput. At the time of her admission to hospital the aphasia alone was observable. The mental faculties and power of locomotion were not manifestly impaired. The labour and succeeding puerperium were uneventful, and when leaving the hospital, about nine days after delivery, scarcely any defect in speech remained. She has been recently seen by me (fifteen months after the beginning of illness), and complains of nothing except slight occasional headache, and a confused feeling in her head if worried or overworked. I could detect no impairment whatever in the power of speech, and she is able to perform all her domestic duties just as before illness.

The rarity of such cases is fully attested by the scanty notices of them in our medical literature, and even the small number here collected, both in their points of contrast and similarity, afford interesting evidence of varying phases and degrees of this affection.

Sir F. Bateman has recorded a very interesting case of a young woman who, during her second pregnancy, suffered from a gradually increasing loss of power in right arm and embarrassment of speech, which culminated in complete aphasia six days after delivery, which was natural and unattended by any unusual effort. The loss of speech was sudden, unattended by any loss of consciousness, and her appearance was as usual. Without developing any fresh symptoms, she became gradually weaker, and sank from exhaustion six weeks after her confinement.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.
SECTION OF STATE MEDICINE.

MEETING HELD ON FRIDAY, APRIL 25TH, 1902, AT THE
ROYAL COLLEGE OF PHYSICIANS.

DR. NINIAN FALKNER, President, in the Chair.

DR. MARTLEY, Hon. Sec. of the Section, read a communication from Dr. M'Vittie "On a Case of Lead Poisoning." The patient, a retired Indian officer, æt. 58, after three months' residence in his new house, began to complain of general seediness, loss of appetite and muscular weakness; he got worse, and in a month was

affected by severe abdominal pains. Two months later he had vomiting and constipation, and he noticed a "fumbleness" of his hands. He was treated for gout, and ordered to Buxton. As he had no teeth the gums showed no lead line. The water supply came from two wells situated above the house, and was conveyed hence in iron pipes which ended in a few feet of leaden pipe to which the tap was attached. Water taken from the tap was found to contain 1.67 grains of lead, that from the wells was pure, soft, slightly peaty. Since discontinuing the tap water he has become completely well. Of all the household he alone was affected; this was probably due to his age and to his having lived some time both in India and Burma.

Sir C. CAMERON, C.B., considered Dr. Martley's communication of interest from the exceptionally large amount of lead present, greater than is usually found except in the case of acid solutions. The water pipes used in Dublin consist of an alloy of tin, 8.5 per cent, and lead, 91.5 per cent. This has, after years of trial, been found to resist the solvent action of water.

Dr. McWHEENY: The case is interesting from many points. We find that a few feet of lead pipe yields to a soft water an unusually high percentage of lead. How could it produce this effect? He is inclined to think that the two metals, the iron and lead, generated electricity, the presence of which produced the solution of the lead. From the clinical history, which says nothing of the patient's urine, he is disposed to think that the patient had some inherent peculiarity of constitution. He (the patient) may have had some chronic kidney disease. An examination of the interior of the lead pipe would throw some light on the subject; they would, at all events, see if there were any carbonates deposited.

Dr. DE LIZLA, of New Zealand, a visitor, at the request of the President, spoke. He said that in New Zealand lead poisoning was practically unknown. He had seen two cases only, and they were painters. He ascribed the immunity to the hardness of the drinking water in their towns. But before he settled in the country, during his life in Sydney, whilst lying ill with typhoid in the General Hospital of that city he saw many cases, the victims being heavy beer drinkers, and the liquor was contaminated with lead from the leaden pipes of the beer machine. The drunkards of Sydney are beer drinkers; their moderate drinkers take whisky.

The President (Dr. Falkiner) recalled to the recollection of the members the very interesting meeting of the Section in 1878, when Dr. O'Carroll brought the subject of lead poisoning from hair dyes under notice. Lead, as many of them no doubt knew, was found in water derived from mineral sources. Of this nature was the Pudesey poisoning outbreak that caused so much excitement in the past. He congratulated the Section on the action of their hon. secretary, who had brought the interesting case forward, and Dr. McVittie, in recognising the nature of the case. He felt sure not unfrequently cases of lead poisoning escaped notice in their early stages, and it is all the more creditable to the physician who diagnoses such in their beginning.

Professor E. J. McWHEENY then read his

CONCLUDING REMARKS ON THE INFECTIVITY OF THE MILK OF COWS WHICH REACT TO THE TUBERCULIN TEST, BUT ARE NOT CLINICALLY TUBERCULOUS.

Ever since the introduction of the tuberculin test he had taken a warm interest in this question. The problem that presented itself to him was, should the milk of cows that react to the tuberculin test be permitted to be sold for human consumption? He commenced his experiments by trying to learn the percentage of milch cows that react to the test. For this purpose he examined a herd of cattle numbering between 80 and 100 animals that were kept under hygienic conditions very much superior to ordinary herds, and of these cattle kept under the most favourable conditions 50 per cent. reacted positively to the tuberculin test. He afterwards, in the South of Ireland, examined a herd of cattle that was not kept under the same favourable conditions, and of these 80 to 90 per cent. reacted to the tuberculin test. To decide that the milk of animals that reacted to the test was unfit for food would be to cut off the milk supply and be impracticable. Some of the

animals vigorously reacted to the toxin, the temperature rising from normal to 105°, 106°, and even to 108°. Strange as it may appear, he found the infection to be inversely proportionate to the extent of the tuberculous lesion, the possible explanation of which might be that the animals which were clinically tuberculous had had their blood immunised by the toxin already in their bodies, and injected tuberculin produced a slight, if any, reaction. In the animals in whom violent reaction took place he found not more than one or two caseous glands, most commonly in the posterior mediastinum. All these statements are based on post-mortem experiments, for every animal he experimented on was afterwards killed. Such animals as those that had such encysted little masses of tubercle gave milk in which tubercle bacilli could not be found. He then described a series of experiments he instituted to test the effects of the milk of cows giving a reaction to tuberculin, but not clinically tuberculous. He reminded his hearers that "acid-fast rods" simulate bacilli, and have been mistaken for them. Almost identical experiments, but conducted on a much larger scale, were carried out in Berlin by Perstatay, who fed young animals, calves and pigs, on the milk of tuberculous cows, but in whom the disease was not clinically demonstrable. The calves were fed for two months and the pigs for seven months on the milk, and in not a single instance did tubercle develop. The milk was perfectly innocuous. We now come to consider a very infectious form of the disease, that in which the cow's udder is infected. The least amount of tubercle in the udder makes the milk poisonous. Bang, of Copenhagen, gave a litre of milk extracted from a cow with a tuberculous udder to a pig, and the animal died as if poisoned in a short time. The percentage of infected animals whose udders are tuberculous is calculated to vary from 2 to 4 per cent. In his own experience he has never come across a case of infected udder; there is no difficulty in recognising it, any educated veterinarian should be equal to the task. So far as his experience goes he considers bovine tubercle to be capable of infecting the human being.

The President (Dr. Falkiner) would offer one remark in the nature of a criticism: Are the cows in dairy yards submitted to a daily inspection? Is the cow recognised as infected allowed to remain in the byre? If so he cannot accept the views put forward.

Dr. McWHEENY said that theoretically the view of the President was correct; but practically the rupture of a tuberculous cyst in the cow was unknown. The yards are inspected at short intervals. In very marked cases, clinically demonstrable, tubercle bacilli may occur in the milk without the udder being infected. Personal inspection by a skilled veterinarian would be inadequate for the detection of tubercle. No person other than a skilled bacteriologist could detect the presence of bacilli in milk.

Sir C. CAMERON, C.B., then read his paper, "Inspection of Dairy Sheds." He thought that dairy inspectors should not be satisfied with the sterilisation of the milk, other matters appertaining to the hygiene of the cowsheds and the dairy should be looked after. Inspectors in rural districts are not at all so careful as our citizens, neither are the rural cowsheds and attendants as clean as city sheds and attendants. Milk is liable to infection from typhoid fever and tubercle, the former after it has been yielded, the latter from the health of the animal. He considers that all inspectors of dairies and creameries and sanitary authorities dealing with our milk supply should be under the authority of the agricultural department. The conditions under which cattle are kept in the rural districts is very unsatisfactory.

Dr. KIRKPATRICK believes that in the direction indicated in the papers there is room for much good work. Hampered by Koch's theory scientists appeared to the public as divided on this sanitary question, and consequently could not hope for lay support. The danger could hardly be overestimated. McFadden estimated that 70 per cent. of the cattle were tuberculous, statistics verified by examination after the slaughter of the animals. The dairy yards of the city were well adapted for the growth of bacilli. Cattle whose lungs are in-

fectured are a constant source of infection to the others. Pure milk exposed, as it often is, in these dirty byres in wide, open vessels, is readily infected by tuberculosis.

Dr. MATESON thinks that feeding of the cattle is of importance. He has seen in Canada cattle fed in underground cellars fattened on grain for the English market. Animals so deprived of natural food and fresh air cannot be healthy, and such cows cough and vomit matter which is almost certain to convey tubercle. The precaution of boiling all milk before use should be adopted.

Sir CHARLES CAMERON, C.B., just wished to remind the members that the recent Viceregal Sanitary Commission declared that the cows in the city dairy yards were much better fed than those in the rural districts. They stated that the Dublin dairy yards were incomparably superior to those in the urban districts; the hygienic arrangements better and the milkers and other attendants much more clean. The Dublin cows are sent to graze for seven months of the year; their milk contains 14 per cent. of solids as against 12 per cent. in the country. A veterinary surgeon examines their udders regularly during the winter season, and the personal cleanliness of the attendants is ensured by a bye-law which makes dirty hands punishable by a fine, and during the last year forty milkers were fined for having their hands dirty.

Professor McWENNEY believed that a codification of our sanitary laws was a necessity; as it is, a whole library of legal books is wanted to find out the law on sanitation. They (sanitarians) want one big Act which will include everything. Sterilisation of milk is out of the question, it makes ordinary milk unsightly and unpalatable, spores resist boiling for three hours under a pressure of two atmospheres. Pasteurisation kills typhoid germs at a temperature of 140° F., and 190° F. kills the tubercle bacilli; no creamery should be allowed to vend milk until it has been properly pasteurised. As for the Dublin dairy yards, he considers them a disgrace to civilisation; they are kept in an intolerably filthy state, and, as for the attendants, he thinks if they had the German sanitary law in force here some 90 per cent. of the milkers would be arrested, and be forcibly washed. The condition of the cows with their flanks caked with faeces and their unwashed udders in city byres, where the fresh milk is allowed to remain in open shallow vessels in which not unfrequently faecal matter floats is abominable. In Germany the faecal matter would be washed off the cow, and the milk would not be allowed to remain in the byres to be infected. Cows cough and sneeze and usually swallow some of the sputum, passing the tubercle in the faeces, and of course infecting healthy animals and contaminating the milk. There can be no proper supervision of dairies without a bacteriologist; a veterinarian cannot make an exhaustive microscopic examination of milk or perform the necessary biological experiments; this is the work of a biologist, and can be done by a biologist only.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, APRIL 24TH, 1902.

MR. WATSON CHEYNE, F.R.C.S., President, in the Chair.

CLINICAL EVENING.

Dr. SAVILL showed a woman, *æt.* 39, a cook by occupation, who was the subject of "erythromelalgia," or sclerodactyly. She had had a general eczema of the hands, which started fifteen months ago. The skin was now cured of any eczematous element, but there was left a sclerotic condition, which for some months had prevented proper movement of the fingers. The redness was almost limited to the digits. All her other skin was healthy. There was a history of numb dead hands, much the same as in cases of Raynaud's disease. She could not resume her occupation because she was unable to close her hands. The fingers were tapered in the way usually observed in circulatory disorders.

Dr. ALEXANDER MORISON showed a baby, seven months old, which exhibited a great "enlargement of veins" passing from the vertex of the head to the left ear. When the baby was quiet, a venous pulsation could be

detected. There was some tension of the fontanelle. Nothing wrong was noticed until the child was three months old. It was the third child of the family, the first having aborted at five months, and the second child was now four years of age. A French physician had published a description of the condition, recounting fifty cases, and he stated there was a specific history in all the cases. The French author thought such children eventually got well. Dr. Morison thought the specific character of the condition was not made out. The present patient had been treated for syphilis and for rickets.

Dr. CAUTLEY was not prepared to accept the congenital syphilis theory of the causation. He had seen cases without such history, and where there was marked obstruction to the circulation. In one case of great obstruction the child developed hydrocephalus, and the obstruction was found to be due to a tumour. Assuming the syphilitic causation of the disease, what was the lesion which would produce such a dystrophy? The unilateral condition sometimes met with might be due to the fact that the communications between veins were more free on one side of the head than on the other.

The PRESIDENT showed a man, *æt.* 40, on whom "epididymectomy" was performed eleven years ago for tuberculous disease on the right side. Two and a-half years ago he came with tuberculous disease of the left testicle. Mr. Cheyne excised the epididymis and vas deferens, leaving the body of the testicle, with the vessels going to and from, intact. The result was that the body of the testicle remained well nourished, and on superficial examination there was not much missing apparently. The operation was done by clean cutting, not by scraping. Great care had to be taken not to injure the vessels supplying the testicle with blood in removing the globus major. Mr. Cheyne dealt with the mental aspect of such operations, and the importance of leaving the testicle if possible.

Dr. EISEN RUSSELL showed and demonstrated a case of "idiopathic muscular atrophy." The subject was a man, *æt.* 45, the disability having come on three years ago, up to which time he had been a coal porter. Sixteen months ago his left arm began to give out. The face was also affected, chiefly in the orbicularis palpebrarum and the orbicularis oris. He was the only child and no other member of his family seemed to have been similarly affected.

Dr. Cautley took part in the discussion.

Mr. STANSFIELD COLLIER showed a youth, *æt.* 17, who five years ago was very severely burnt on both feet and legs, leaving a patch over the front of the left tibia which never healed, the ulcer having several times broken down. He performed the Tagliacotian operation, examples of which were seldom seen now. There were advantages in that operation when dealing with an ulcer, the bottom of which was bone very thinly covered with very dense scar. He took the flap from the upper part of the back of the right leg, and left the flap attached to both limbs for a fortnight. The raw surface caused by the removal of the flap had been covered with Thiersch's graft, and had nearly healed.

Mr. RAYMOND JOHNSON read a short paper on Some Points in the Treatment of

TUBERCULOUS DISEASE OF THE KNEE-JOINT.

Doubt was expressed as to whether tuberculous disease of a joint is ever recovered from without some degree of fibrous ankylosis. It was pointed out that a considerable proportion of the cases of supposed tuberculous disease of joints followed by perfect restoration of movement occur in the hip, in which the distinction between early tuberculous disease and other affections is particularly difficult. In the knee the results of non-operative treatment were usually unsatisfactory, for a degree of mobility was often left which was detrimental rather than useful, in that gradual flexion of the joint frequently followed. Such a condition often called for operative interference, with the object of converting the partial into a complete ankylosis. For similar reasons the operation of simple arthrectomy or erosion was often unsatisfactory, and it was advised that even though the articular surface

were healthy, these should be removed, in order to obtain with greater certainty firm ankylosis. After all operations a long period of fixation was necessary.

CONGENITAL HÆMATURIA.

Dr. LEONARD GUTHRIE read a paper on this subject, of which we publish an abstract on page 484.

Dr. ATLEE mentioned a case under his care in which the blood was bright red. Sometimes it cleared up altogether. In one case between the attacks there was albumin in the urine, but no blood.

Dr. SUTHERLAND inclined to the view that the cause of the condition was some vasomotor change. In some respects the similarity of such cases to cyclic albuminuria was very marked. Perhaps the lesion was a renal one, purely localised. He asked whether the patient had had hæmorrhage from any other organ, and whether in any cases there had been a development of Bright's disease.

The President and Dr. Cantley took part in the discussion, and Dr. GUTHRIE replied.

LIVERPOOL MEDICAL INSTITUTION.

CLINICAL EVENING.

Mr. RUSHTON PARKER, B.S., F.R.C.S., President, in the Chair.

SIR WILLIAM BANKS showed a collection of loose cartilaginous bodies removed from the knee-joint of a woman, æt. 26. They were over forty in number, and varied from the size of a bean to that of small shot. There was a history of two falls upon the knee, the first eight years previously and the second four. After the latter there was always weakness and pain in the joint, and recently, when walking, the patient has been seized with sudden and violent pain, while she was compelled to clutch any support at hand to prevent falling. The knee was then semiflexed. Several loose bodies could be felt in the articulation, which contained a good deal of fluid, and was painful and useless. A semilunar incision was made above the knee, and the flap, including the patella, thrown down. The whole joint thus thoroughly displayed was cleared partly by forceps and partly by means of a strong stream of water, which flushed every pocket in it. The quadriceps tendon and muscles were brought together by deep sutures, and perfect primary union was obtained. The patient, who had only left hospital three weeks previously, had perfect movement of the joint. He also showed one-half of an enlarged parenchymatous thyroid gland removed from a girl, æt. 18, with whose respiration it had begun to interfere. At the removal it was found that the trachea was flattened from side to side. The patient was shown with the view of illustrating the effect of removal of one-half of an enlarged gland upon the remaining half, viz., atrophy. He advocated cleaning the isthmus first of all, ligature thereof followed by division, and then removal of the half gland by dissection from the middle line outwards. He considered this an infinitely safer and easier method of procedure than beginning to remove the gland from the outer margin.

SIR WILLIAM BANKS also showed a number of crushed stones and a large adenoma of the prostate removed from a gentleman, æt. 76, with an enormously enlarged prostate, who had not passed any water for fifteen years except through a small catheter. The operation consisted of a median cystotomy with crushing of some half-dozen stones. He believed this form of lithotripsy through a median perineal incision would be the future operation for lithotomy in old men.

Dr. FRANK H. BARENDT showed two cases of "prurigo."

Mr. THELWALL THOMAS read a note on the value of "Tenotomy of the Tendo Achillis in Complicated Fractures of the Lower Extremity." He had practised it with particular success in fractures above the condyles of the femur, oblique fractures of the tibia, and in fractures of the tibia and fibula immediately above the ankle-joint. He thought this simple proceeding was apt to be lost sight of with the prevailing rage for "screws" and "wires."

Fractures that united with any degree of deformity distorted the line of weight-bearing in the limb, and altered the relative position of the joints to this axis, and until met by a new development of bony trabeculae the limb was very much disabled. He considered it essential that every fracture should be accurately reduced soon after the injury, and less trust be placed in pads for pressing fragments into position during consolidation. Tenotomy enabled this to be readily carried out in the above-mentioned fractures, where extreme flexion would otherwise be necessary, and the need for more serious operations would become less frequent, and tedious convalescence materially diminished. The use of X-rays would help to verify the position if any doubt might exist.

The PRESIDENT said that it was evident that tenotomy of the tendo Achillis must be good sometimes under certain conditions of manipulation and manipulative skill, but that the necessary relaxation of the calf muscles in cases where the first adjustment was difficult could generally be effected by bending the limb freely at the seat of fracture, and so without much force permitting the broken fragments to be put easily into apposition. Linear traction in such cases, if employed before adjustment, necessarily failed by locking the fragments in a bad position.

Mr. E. W. MURRAY said that under ordinary treatment an oblique fracture of the lower end of the tibia reduced a labourer's wage-earning capacity by at least 50 per cent. There was extreme difficulty, not only in reducing the fracture, but also in maintaining correct apposition, even when the site of fracture was exposed by a free incision under an anæsthetic. On these grounds he strongly advocated wiring or screwing in these fractures, whether simple or compound.

Sir William Banks and Mr. F. T. Paul also spoke, and Mr. THOMAS replied.

OPERATIONS FOR HERNIA.

Mr. G. P. NEWBOLT read a paper based upon 120 consecutive operations for hernia, radical and strangulated. There were seventy-seven operations for radical cure and forty-three for strangulation, in most of which a radical operation was also performed. The radical operations consisted of seventy inguinal, two femoral, three umbilical, and two ventral, and there was one death from simple pneumonia in a child, aged 19 months. Of the forty-three cases of strangulation twenty-eight were inguinal, eleven femoral and four umbilical; ten of these died, i.e., six inguinal, two femoral, and two umbilical. Altogether 114 patients were operated upon, ninety-seven operations being done on males and twenty-three on females. Out of thirteen cases of femoral hernia only one occurred in a male, and out of ninety-eight inguinals only five occurred in females, and two were strangulated. The youngest patient operated upon was two months, and the oldest was seventy-eight years old. There were two cases of strangulation in young children. The subject of radical operation in children was dealt with and advised in those cases in which treatment by trusses was not likely to be properly carried out. The difficulty in separating the sac from the cord in small babies was commented upon. In large hernias in elderly men the operation of removal of testes and cord, with entire closure of the canal and ring, was recommended. Mr. Newbolt usually performed Macoeven's operation, using silk or kangaroo tendon for ligatures. The question of the taxis was dealt with, and also some points in connection with reduction in mass. Trusses were generally advised after operation except in congenital cases. Two cases of inflammatory trouble after the removal of big masses of omentum were narrated, both terminating favourably. In four cases of strangulation out of forty-three the intestine was resected, and there were three recoveries. Murphy's button was used in each instance, and the operation was done through the herniotomy wound. Eucaine was of service in one case in which the patient was so ill that a general anæsthetic was thought to be inadvisable. The deep epigastric artery was divided accidentally in one instance and secured after some trouble. The vermi-

form appendix was found strangulated in the hernial sac in a case of femoral hernia and was removed. Eight out of the ten deaths occurred in cases which had been strangulated over seventy-two hours, and they were chiefly due to enteritis and peritonitis. The dark colour of the urine due to the presence of indican was alluded to in cases of strangulated bowel.

After complimenting Mr. Newbolt on his paper, the PRESIDENT said that after performing the operation nearly 600 times, he found herniotomy a subject full of practical interest, and often of novelty. In children, irrespective of station, he was in favour of early operation for radical cure. The more he performed it the more he was satisfied that it was both effectual and right, and his later experience simply confirmed his views expressed in the *British Medical Journal* in 1893 and 1895. Macewen's operation was absolutely satisfactory in almost all cases in children. Suppuration in a packed and granulating sac did not in his opinion specially favour a radical cure. In the matter of gangrenous gut no fixed rule of procedure could be claimed as preferable; successes and failures have resulted severally from all. The cases must be dealt with, as in many surgical emergencies, according to the circumstances as ascertained at the time.

Mr. K. W. MONCARRAT considered much of the ingenuity devoted to the invention of new methods of treatment of the hernial sac in radical cure was wasted. The interposition of a muscular barrier was the essential factor. This principle was acted upon in the prevention of hernia through the abdominal wall; it was applied in its simplest form to the cure of umbilical rupture, and was made available in inguinal hernia by Bassini's operation.

Mr. DOUGLAS CRAWFORD advocated radical cure in children of the hospital class. He practised a modified Macewen, but was satisfied with his results with Bassini's operation. With gangrene of the gut he preferred the establishment of an artificial anus, and subsequent repair.

Mr. F. T. Paul, E. G. Hamilton, Damer Harrison also spoke, and Mr. NEWBOLT replied.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD AT THE MEDICAL SOCIETY OF LONDON
APRIL 18TH, 1902.

Dr. LEONARD GUTHRIE in the Chair.

Dr. DAN MCKENZIE showed a case of "cystic hygroma" of the neck which was undergoing spontaneous cure. At birth the cyst had been the size of a small orange, but when shown at the age of eleven months, was barely perceptible.

Mr. WHITELOCKE (Oxford) said he was aware that Mr. Bland Sutton had said these tumours generally disappeared after puberty, but he had seen a case as late as the age of twenty-seven.

Dr. EDMUND CAUTLEY showed a case of the peroneal type of "muscular atrophy" in a girl, *et. 7*. She was the third of five living children, there was no history of similar atrophy of muscles or of nervous disorders in the family, except epilepsy in a brother and sister of the mother. The child showed a "claw-like" deformity of the hands, due to paralysis and atrophy of all the intrinsic muscles, and "club-foot," due to atrophy of the corresponding muscles in the feet of the peronei and of the extensors of the toes. The other muscles below the knees, the vasti interni, and to a less extent the hamstrings, tensor fasciæ femoris and glutei, were also involved. The affection began in early life, and was perhaps secondary to measles at the age of six months.

The CHAIRMAN said there could be no doubt that the condition was one of myopathy.

Dr. FLETCHER BEACH discussed the question of operative treatment of the club-foot, and thought massage might be of some value.

Dr. DAWSON WILLIAMS asked whether Dr. Cautley was prepared to accept the theory of peripheral neuritis. He was glad to hear that Dr. Cautley drew attention

to the probable influence of measles in starting the disease, and thought it easier to believe that such cases were due to the action of toxins upon the nerves than upon the central nervous system.

Mr. H. J. CURTIS thought that tenotomy would not be of much value.

Dr. G. A. SUTHERLAND also thought that surgical treatment in these cases would avail little.

Mr. SYDNEY STEPHENSON showed a case of "tubercle of the choroid" in a child, *et. 8*. There were slight signs of phthisis in the apex of the left lung.

The CHAIRMAN asked about the prognosis in these cases.

Dr. GEORGE CARPENTER referred to a paper which he and Mr. Sydney Stephenson had read before the Liverpool meeting of the Society. He thought there were two classes of cases, one in which tubercles of the choroid were associated with general tuberculosis, and the other, in which they were associated with chronic tuberculous lesions such as spinal caries. He had watched such a case for twelve months.

Mr. CURTIS confirmed Dr. Carpenter's observations. He had seen one of Mr. Stephenson's cases of tubercle of the choroid, and had excised the knee for tuberculous disease. The child recovered and was well three months later.

Mr. SIDNEY STEPHENSON, in reply, said he knew a case of tubercle of the choroid which had apparently dated back for thirty years.

Dr. THOMSON WALKER showed a specimen of "tuberculous nodule" the size of a walnut, arising from the dura mater, which was embedded in the inner part of the left cerebellar hemisphere. Death was due to acute meningitis.

Dr. WALKER also showed an osteoma of the floor of the third ventricle with the formation of a cyst at one part, the symptoms were those of left cerebellar disease, and an exploratory operation had been performed. Only eleven other examples of this tumour are found in literature.

The CHAIRMAN remarked upon the misleading symptoms in the second case; she had right-sided headache, and kept her head turned to the other side; there was double optic neuritis, slight right facial paralysis, tremors of the right arm, and the right knee-jerk was exaggerated, and when placed upon her feet she reeled towards the right. The right side of the cerebellum was found quite healthy.

Dr. SUTHERLAND referred to the first case, and said that while in the hospital the symptoms were those of meningitis; there was no evidence of tumour.

Mr. EDMUNDS commented upon the fact that optic neuritis was present in one age and thought it suggestive of the age presence of a tumour.

Dr. THEODORE FISHER (Bristol) thought a tumour in the floor of the third ventricle might have another clinical interest. It had been thought that the infundibulum and upper part of the pituitary body had an influence upon the nutrition of the nervous system. He had seen a case where a gumma of the floor of the third ventricle and pituitary body was present, yet there had been no symptoms suggesting a brain lesion, and the patient had slowly died and was thought possibly to have contracted granular kidneys.

Dr. BURGESS asked whether urine of the second case showed anything abnormal?

Dr. THOMSON WALKER, in reply, said the urine showed nothing abnormal.

Mr. R. H. A. WHITELOCKE (Oxford) read a paper upon a case of

SUPPOSED STRANGULATED HERNIA

in a female child, which was found to contain an ovary-like body which proved to be a retained testis. A similar body was present upon the opposite side. Photographs of the external genitals were shown. They appeared to be those of a normal female child.

Dr. GEORGE CARPENTER spoke of the value of rectal and bi-manual examination in these cases.

Dr. G. A. SUTHERLAND and the CHAIRMAN discussed the question of sex, and thought the child should be brought up as a girl.

Mr. WHITELOCKE, in reply, thought the question of sex in some cases might be a difficult one, and the question of the right to inherit property might be concerned.

Dr. C. O. HAWTHORNE and Mr. H. J. CURTIS then read a paper upon a case of

NEPHRECTOMY FOR SARCOMA OF THE KIDNEY

in a child, *et. 4*. The child appeared at first to be doing well, but died three weeks later from pleural effusion into both sides of the chest. The tumour weighed 3 lbs. 15 oz.

The Chairman, Dr. Nabarro, Dr. Porter Parkinson, Dr. Theodore Fisher and Dr. Thomson Walker commented upon the case.

Dr. GEORGE CARPENTER read notes on what was proved at the autopsy to be a case of

MALIGNANT ENDOCARDITIS

in a child, *et. 8*. The case came under observation as one of a sudden onset of coma, in apparent good health, with hemiplegia, associated with mitral disease. He recovered from the coma and next developed cerebral symptoms and ocular pareses, and was expected shortly to succumb to tuberculous meningitis, but these symptoms subsequently passed away. Intense optic papillitis, a simulated choroidal tubercle and subretinal hemorrhages were found on ophthalmoscopic examination, which lent weight to the idea he was suffering from a tuberculous cerebral tumour; he did not react to tubercle. Just before his death he developed embolic plugging of the right common iliac artery.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, May 3rd, 1902.

At the Congress for Surgery Hr. Hochenegg (Vienna) read a communication on

THE RESULT OF TREATMENT OF CARCINOMA OF THE COLON.

The cases treated numbered 282. In one case of disease of the cæcum rectal carcinoma at the level of the third sphincter had developed; the carcinoma was very friable, and at the operation small fragments were washed away. In one case of cancer of the transverse colon a special method of operation was carried out. In June, 1894, a man, *et. 76*, was operated on who on the third day thereafter developed ileus, with a good deal of meteorism. On laparotomy the transverse colon was seen to be distended to the right, and examination revealed a small annular carcinoma. The author did not resect at once, but drew the diseased portion out of the wound, sutured it, opened the distended colon, and a week later did the resection. The patient at present feels quite well, so that we have a permanent result for eight years. The operation was also performed in four other cases, twice with good result. In three cases of carcinoma of the flexure health was retained for six years in one, the patient dying of a non-malignant cerebral disease. The second case was that of a man of 70, who was operated on in October, 1900. The flexure was the seat of numerous diverticula, and the disease had commenced in one of them. The third case was interesting as showing that in cases where the occlusion was highest, irrigation did harm. The medical attendant had ordered washing out on account of retention of feces. After this, a tumour formed above Poupart's ligament, which was painful, and accompanied by fever. The speaker found a large infiltration at the spot, and on more careful examination, a large tumour on the left. The infiltration was opened up; the cancer of the flexure drawn into the wound and resected. The patient

was feeling well except, of course, for the artificial anus. The violent irrigation had forced an opening through the intestinal wall. As regarded carcinoma of the rectum very varied results had been given by various operators. The speaker had only made use of the sacral method, and always with a good result. It had been suggested that he had made a careful selection of cases for this operation, but it was not so. He had performed this kind of radical operation in 72 per cent. of his cases, in the remainder only palliative measures were admissible, and these were not included in his statistics. The number of his radical operations was 174, and this showed that selection was not much made use of. He was very careful, however, and when in the course of an operation success did not seem probable, he preferred abandoning it rather than to complete it. In order to arrive at some clearness as to the mortality in the hands of different operators he had examined the cause of death. He grouped them in two series—(1) direct result of operation, (2) disturbance during the progress of the wound. He had lost only one case from collapse and one from hemorrhage on the eighth day, whilst other operators showed larger numbers from these causes. He could show a large number of permanent recoveries—30 in 174 operations—when the patient had remained free for over three years. Ten cases had complete, and two a comparative, continence.

Hr. Krönlein compared

MEDICAL TREATMENT OF CANCER OF THE STOMACH with that by operation. Since the hopes raised twenty-two years ago by Billroth's first successful resection of cancer of the stomach, opinions were now again gradually becoming pessimistic. Even among surgeons there were doubts. He had thought therefore that an inquiry and a balancing of the results would be useful. Was operation curative or palliative? Could life be prolonged if not saved, or only made bearable for a time? He had collected notes of 284 cases, of which 195 had been operated on, whilst 89 were not operated on, 54 because operation was not admissible, 14 because they declined to submit to it. Exploratory laparotomy was performed in 71 cases with 7 deaths; gastro-enterostomy in 74 cases with 18 deaths, and gastrectomy in 60 cases with 14 deaths; total deaths 39 - 19.4 per cent. As regarded permanent results he had only failed to obtain information as to 4 per cent. of the cases. The average duration of time between the first appearance of symptoms and admission into hospital was nine months. If patients were now submitted to operation the average duration of life was another 104 days; so that the average life from onset of symptoms was about one year. Patients went, therefore, first to the surgeon when three-fourths of their space of life had already run out. After gastro-enterostomy the average existence was 193 days, a prolongation of about three months. After gastrectomy they lived 420 days, a lengthening of life of about fourteen months. Of the gastro-enterostomy cases nine were still living, and of the gastrectomy thirteen. Of these one was healthy in the eighth year after operation, one in the fourth year, two in the third, three in the second, and six in the first. As recurrence took place late in carcinoma of the stomach, freedom from disease for three years could not be accepted as a permanent recovery. The figures showed at least that surgery offered some improvement on the hopeless outlook of

internal treatment only. It not only prolonged life, but rendered it more bearable. This was especially the case in gastrectomy, which rendered even a radical cure possible. The speaker concluded with the wish that the operation, like that of extirpation of the vermiform appendix, might become more popular, not only with the surgeon, but also with the public. With early operations even better results might be obtained.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, May 3rd, 1902.

GENERAL LYMPHOMATOSA.

At the "Gesellschaft für innere Medizin" Shur showed preparations of blood taken from a case he showed to the Society in December, and who died on the last of January. In the sputum, *usque ad finem*, no tubercle could be discovered, while all bacterial preparations proved negative.

There were a few subjective symptoms, which he viewed lightly, might be noted before he expressed his views, viz., pressure on various parts of the body which gave pain, more particularly the extremities, the left one especially about the hip.

There was no anatomical lesion to show the possibility of tuberculous origin, neither was there amyloidosis to prove tuberculous pseudo-leukæmia. The post-mortem diagnosis affirmed that it could not be a case of simple pseudo-leukæmia, or no other complication ought to exist. In this case there was a myelocystic metaplasia in the shaft of the femur as well as in the ribs and sternum. Nowhere could tubercle of the marrow or bones be found. It was therefore concluded that the blood was the source of primary affection.

On criticising the post-mortem results, in which the operator expressed the opinion of pseudo-leukæmia as a basis of tubercle, with fibrous induration of the lymphatics, he thought this was strongly presumptive, as the spleen had the same tubercular pseudo-leukæmia, which may have become chronic as there were small glands that had even become cheesy. There were also pseudo-leukæmic tubercles in both lungs, with amyloidosis in liver, spleen and kidneys, with hydronephrosis on the right side.

The microscopic examination proved the case to belong to that class of cases Sternberg has proved in his work on the subject denoted pseudo-leukæmia in the course of tubercle, as they contained a characteristic giant-cell; while Langhaus found this cell with genuine tubercle. Tubercle bacilli were actually found by the microscope in the small lymphatics along with eosinophile cells; the presence of these cells militated against the opinion of a malignant lymphoma, but were in favour of a tuberculous condition.

Shur affirmed that he had examined the whole history of medicine to find a parallel case, but had failed. In Sternberg's cases the clinical examination negated all leucocytes or only a very slight reduction of the leucocytes, which would prove the foregoing case not to be one of tuberculous pseudo-leucocythæmia.

There are two notable points to be observed in the blood constituents of this case: first, in spite of the duration of the leucocytosis no mononuclear granulated cells, myelocytes, were to be found. It may be accepted

that the appearance of a large number of myelocytes is a symptom of diseased cells which indicates a loss of the amoeboid movement and a determination of nucleus; secondly, that after many years' duration under severe irritation of the marrow, nowhere could nucleated red blood-corpuscles be found.

Schrotter asked whether the bronchial glands, tonsils, or tonsillar-pharyngeal glands had been examined, as this might be the primary channels of attack; to which Shur said the broncho-lymphatics were swollen, but the pharynx and tonsils were not.

Türk thought "tuberculous pseudo-leucocythæmia" should be banished from the mind, and the case simply regarded as one of tubercle. From his own investigations of the blood a very large number of leucocytes do not alter the relative proportion of the blood, while there are others in a different stage, or a third with eosinophiles and leucocytes to the extent of fifteen, twenty, or even as high as thirty-eight thousand. When the constitution of the blood becomes inconstant there is a symptom of high temperature, fever, and accompanied with the typical hectic type, usually termed pseudo-leucocythæmia, which is neither less nor more than tuberculosis; failing these clinical symptoms, the case becomes one of tuberculous lymphomatosis. The glands in tuberculous lymphomatosis are for the most part painful, indolent with much hyperplasia, and on looking at the symptoms of Shur's case with pain, swollen glands, and altered condition of the blood, little doubt need be entertained on the case.

In tuberculous lymphomatosis you never find diffuse tubercle-nodules or swelling in the lymphatic apparatus either in the mucous membrane of throat or mouth, but in hyperplastic lymphomatosis swelling is the general rule.

Now a diagnosis from the blood alone of hyperplastic lymphomatosis is not possible as there are cases of real genuine hyperplastic lymphomatosis without any lymphocytes at all, but are irrefutable in their clinical aspect but may be distinguished from pseudo-leucocythæmia. (1) General hyperplastic lymphomatosis has no local aggressive character. (2) Lymphomatosis with local character (lymphosarcoma) has usually no lymphocytosis: (3) Lymphomatosis with small local swellings has occasionally lymphocytosis.

The Operating Theatres.

ROYAL FREE HOSPITAL.

EXAMINATION OF AN APPENDICULAR ABSCESS AFTER A FORTNIGHT'S APYREXIA.—Mr. E. W. ROUGHTON operated on a case of appendicitis. The patient was a boy, æt. about 12, who had been admitted a fortnight previously suffering from a typical attack of appendicitis. On admission his temperature was 102°, and there was a tender swelling in the region of the appendix. The question of immediate operation was at that time seriously considered, but as the symptoms were not very urgent, and showed a tendency to abate rather than to become more severe, it was decided to treat the case in the first instance by medical means only. All the acute symptoms very rapidly subsided, the temperature and pulse becoming normal in the course of forty-eight hours. The patient was then allowed to remain quietly in bed for ten or twelve days, during

which time he had no symptoms whatever, the tenderness over the appendix disappeared, but an ill-defined lump could still be felt. Mr. Roughton before operating said that it would be much better for the boy to be submitted to operation rather than to be sent out and allowed to run the risk of having further attacks. An incision three inches long was made parallel to the outer half of Poupart's ligament, the abdominal muscles being divided in the direction of their fibres. On opening the peritoneum a mass of thickened omentum and adhesions was found; the area of operation was then packed off with sterilised gauze. The adhesions were next cautiously separated, and a small abscess cavity was discovered, from which about three drachms of pus were slowly evacuated, great care being taken to prevent infection of the peritoneal cavity. A search was then made for the appendix, with the result that the proximal inch of the process was found, the rest of it having sloughed off. What remained of the appendix was removed in the usual way, the inflamed omentum ligatured and cut off, a drainage tube inserted into the abscess cavity, and the muscles and skin brought together by suture. Mr. Roughton drew attention particularly to the fact that the rapid improvement which had occurred during the first few days in hospital was to a large extent illusory, although fever and all other acute symptoms had completely disappeared. He pointed out that such a case might quite possibly have been regarded as recovered, whereas future trouble was in reality inevitable. The case, he thought, afforded a strong argument in favour of operating upon all cases of appendicitis after a first attack, even when an apparent cure had resulted after medical treatment.

Six days after operation the patient's condition was extremely good, although a little pus was still escaping from the drainage tube.

Pure Water !

ONE of the 40-inch mains of the Manchester water-supply system was recently cleaned out and no less than seven hundred tons of animal and fungoid growth with mineral matter caught therein were removed. A 36-inch main in use from 1899 to 1901 yielded one hundred and sixty-five tons of deposit. If this deposit represented the whole of the impurities contained in the water all would be well, but such is far from being the case.

Manchester Branch of the National Association for the Prevention of Consumption.

THE recent visit of Sir William Broadbent to Manchester, where he delivered a valuable address on "The Prevention of Tuberculosis," has led to the formation, long talked of and sadly needed, of a branch of the National Association for the Prevention of Consumption, and the Manchester and Salford Sanitary Association are to take steps to arrange for its organisation.

Maxima Debetur Mortuis Reverentia.

WE have all heard, says the *Lancet*, of the American ladies whose sense of modesty was such that they clothed the legs of their tables and chairs in nether garments. The following occurrence at one of the great London hospitals is illustrative of feeling every whit as nice. A cold storage chamber was being constructed in connection with the post-mortem room and the secretary of the hospital, on going to see how the work was getting on, found that the chamber was being fitted with double doors—and those of small size—instead of one large door. He made inquiries as to the reason for this deviation from the original plan when the chief carpenter, who was superintending the work, replied: "Oh, sir, we are putting in double doors and a wooden partition in order to keep the sexes apart!"

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d., Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantships, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion 6d. per line beyond.

LIGHT AND SANITATION.

WE look back with mingled amazement and pity on the uncomfortable and unsanitary conditions of existence which our forefathers were content to put up with until the great fire came along and simplified the problem of rebuilding the city in accordance with more enlightened principles. Elementary as were the ideas of our ancestors in respect of personal cleanliness and public hygiene, we must admit that their conditions of environment were in some respects superior to our own. They at any rate had not far to go to get into green fields and fresh air; the air they breathed was not contaminated by admixture with thousands of tons of coal converted into smoke and the sun poured its vivifying rays into the city comparatively unhindered by murkiness of atmosphere. Outside the city proper most houses, great and small, had their gardens where the citizen could retire after his day's labour to breathe an atmosphere not, as now, deoxygenated by the lungs of six million people. The main roads leading into the country, north, south, east and west, of which in most instances only the bald lines remain, were broad avenues with a deep fringe of verdure and flowers. As we have improved in some directions we have retrograded in others so that, if the last state be not worse than the first it is not as much better as we, in our vanity, are apt to suppose. We have come to recognise the beneficent influence of plenty of fresh air, but in practice we fail to avail ourselves of that of light. In his address before the Sanitary Congress at Manchester, Sir James Crichton Browne dwelt upon the effects of direct sunlight in promoting health and the enjoyment of life. Apart from its well-known destructive action on certain varieties of disease-producing germs, its stimulating effect on retrogressive oxidation, hastens decomposition and curtails the stage of putrefaction.

Light, indeed, has still deeper and more intimate human relations of a sanitary character, in that it is a necessary condition of mental and physical well-being. Pure white light is "the normal cerebral atmosphere." The gospel of the future will be "big windows and open doors," with plenty of open spaces, though the doctrine of floor space is being deliberately contravened in the Metropolis by the construction of huge barracks specially designed to admit of a large increase in the number of human beings housed per acre. The problem of providing more light is intimately associated with the smoke question, since it is the smoke which, in our large cities, is the most effectual barrier to the sun's rays. We have secured, more or less, the purity of our water supplies, we have sacrificed untold millions in order to prevent further contamination of the soil, we have still to undertake the task of purifying that even more important factor in our physical existence, the air we breathe. Fortunately the dawn is perceptible above the chimney-stacks, the steady progress of electricity for lighting and warming, and as a source of power for manufacturing purposes, promises to minimise the evil entailed by the griminess of steam. The steady rise in the price of coal, distressing as it may be to the present-day householder, will give an impetus to more economical methods of procuring warmth for domestic purposes, and economy means less smoke individually from the six hundred thousand houses of the metropolis. With the disappearance of the superabundant smoke, then will the grass grow green again, the herb flourish after its kind, flowers blossom in our urban gardens, moss and lichens mantle on our city walls; then will the faces of our toiling millions again be burnished with the glow of health, while the pale pestilence that walketh in darkness will alink away abashed. Then, too, it may be hoped, the sleeping spirit of beauty among us will awake at the touch of the auroral prince from her long fume-begotten torpor, so that ugliness may depart from our streets, and the glories of architecture again adorn them, while the refining influences of art exalt the national life." Such an ideal may perhaps seem Quixotic to the dwellers in Cottonopolis, but it breathes the spirit of scientific prophecy. Sanitary reformers at least in their methods of work have so to agitate and educate as though nothing had been done so long as anything remains to be done.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND ITS LICENTIATES.

THE motto which was chosen by the fathers of the unum Corpus et Communitas perpetua sive Collegium perpetuum, the Royal College of Physicians, must have been a subject of much consideration and debate among them. "Life is short but art is long" ("Ὁ βίος βραχύς ἡ δὲ τέχνη μακρά") suggests much that may encourage some and depress others, and we fear that the latter effect may be now making itself felt on the College in Pall Mall. Nearly four hundred

years have passed since H.M. King Henry VIII. granted to John Chamber, Thomas Linacre and others, the Charter of Incorporation of the College, which raised the practice and profession of medicine from its rather doubtful character into one of great public importance and national benefit. It has been the fate of many institutions, companies or societies which started and were powerful three or four centuries ago to have gradually changed to such a degree that they have practically died out. The arts or purposes they were devoted to have lived, for ἡ τέχνη is μακρά, though ὁ βίος is βραχύς. When the Charter of Incorporation of the College of Physicians, with its sidenotes as printed and published, are carefully studied, as they ought to be, by those interested in any questions concerning Fellows, Members, or Licentiates, it will be seen that if the "reasons for incorporating—viz., to check men who profess physic rather from avarice than in good faith, to the damage of credulous people," exist now as they did in 1508, the College does certainly not make this a matter of its special care or duty. The public is now protected by so many chartered societies, whose duties are the same as those undertaken almost solely by the College of Physicians in the time of Henry VIII., that the question arises whether it would not be better for the College to consider the second part of its motto than in trying to do what has been amply provided for, in direction of checking "men who profess physic . . . to the damage of credulous people." In the year 1522-23, that is, four years after the Charter of Incorporation was granted, the very important extension was legally allowed of the radius of seven miles round London to the whole of England, and "that no person from henceforth be suffered to exercise or practise in physic through England, until such time as he be examined at London," &c. What great changes have taken place in the relations between the Royal College of Physicians, the profession and the public since 1522-23, we need not now remark upon. The public is protected so widely and by so many chartered corporations and universities, and lastly by the General Medical Council, that the College is not called upon to give special attention to the purposes for which the leaders of the profession obtained the first charter. Under these circumstances some might take the view that the βίος of the College, if it has not been βραχύς, it has been μακρός enough; unless, as we have suggested, it sees some way of working for the public good. Some may take the view that the interests of the profession ought to be considered, and in this we heartily concur; but at present it rather looks as if the great body of Licentiates of the Royal College of Physicians of London were under disadvantages which other licensing bodies in Great Britain do not impose. So far as the qualifications of those who wish to practise are considered, it looks as if the General Medical Council were inclined to require a higher standard than that of the College, and that in such matters as registration and education of

students the College is disposed to be less particular and exacting than the Medical Council. There is another matter to which undoubtedly attention should be given both by the licensing bodies and the Council, and that is the practical teaching of students, a subject more important by far than that of examinations. It was the university system of teaching that gave Oxford and Cambridge the privilege of being independent of the College when it obtained its charter; and there is no doubt that the College has done its best to assert itself over the great Universities of England. It is true that the Universities may have deserved such treatment by neglecting in a singular manner the education of students in the art and science of Medicine. Things have been improving, however, during the past few years, and we hope they will continue to do so. Now that the licence to practise Medicine and Surgery in England can be obtained in so many other ways, it would be well for the College of Physicians to turn its attention to the improvement of the profession rather than to that of making something out of the granting of licences, and to consider how it may avert the fate of *βίος βραχύς* by some attempts to make its *ταύτη μακρή*.

Notes on Current Topics.

Proposed Abolition of the Midwives Training School of Sir P. Dun's Hospital.

THE Board of Governors of Sir P. Dun's Hospital has, in a somewhat sudden and apparently unaccountable manner, decided to abolish the training school for midwives which has been attached to the hospital since the time of Sir Edward Sinclair. The fact that they have decided on so important a step without communicating with the Royal College of Physicians—who appoint the King's Professor of Midwifery, the medical head of the school—and contrary to the wishes of the King's Professor, has, we learn, given rise to some not unnatural indignation on the part of the College. The reasons for the abolition of the school are apparently obscure. Its nurses hold an admittedly deserved high reputation. The numbers trained annually have increased from seven at the time of the appointment of the present King's Professor to more than thirty. The results of the cases treated can more than bear comparison with any lying-in hospital in the United Kingdom. In spite of this, the school is to be abolished and no more nurses are to be admitted for training after June next. It is difficult to surmise the reasons which have led the Governors to this—we cannot but think ill-advised—decision. A number of trained midwives spread through the country must be of value to the hospital which trained them. And for this reason, if for no other, we should have thought that the Governors would do everything in their power to increase their number, more especially at a time when the Poor Law medical service is recruited to so small an extent from the students of Sir P. Dun's. We can

only attribute their decision to a desire to economise, but this, we fancy, would be better met by making the nurses a source of profit to the hospital. The President and Censors of the College of Physicians are *ex officio* members of the Board of Sir P. Dun's Hospital, and we trust that as a result of their presence the general body of the Governors will be led to alter their determination to close a valuable school, especially when by so doing they will, as we understand, run counter to the wishes of a body with which they are so closely connected as they are with the Royal College of Physicians.

Meat-juice and Marking Ink.

OR all places in the world a hospital for the sick should be administered with rigid attention to detail and order. That such is not always the case is abundantly shown by the reports of the coroners' courts. Hardly a week elapses without the tale of some death in a public institution of the kind due to gross negligence and want of method. Not very long ago we commented severely upon the carelessness which allowed strong carbolic acid to be left lying about in a ginger-beer bottle at one of our leading London hospitals. The result was the death of a workman who took a pull at the bottle under the impression it contained some harmless beverage. The latest scandal of the kind comes from the fever hospital near Bromsgrove, where marking-ink was given in mistake for meat-juice to two scarlet fever patients? Will it be believed that in a public hospital marking-ink was habitually kept in a meat-juice phial and left where it could be administered to a patient! It is all very well for a hospital committee, wise after the event, gravely to censure a nurse for stowing away the marking-ink along with medicines and food. The fault lies with the system, or lack of system, that allows marking-ink to be placed in any but a properly labelled and distinctive bottle of its own. Most marking-inks are poisonous. It would be interesting to know what are the ward regulations at the Bromsgrove Infectious Hospital regarding poison bottles and poison cupboards; or do the dispensers utilise odd bottles and phials for all poisons needed in the wards?

Zenana Medical Work.

ALL creeds of modern Christianity appear to be recognising the fact that it is necessary to look after the bodily as well as the spiritual welfare of mankind. In pursuance of that principle the addition of the medical element has immensely increased missionary influence throughout the world. Here at home in the Mother Country the two things are usually kept apart, as the vast majority of the medical charities are strictly undenominational. Abroad, the combination of medicine with the teaching of the principles of the Christian religion has nowhere been more conspicuously successful than in the case of India, where the religious scruples of the people exclude the attendance of medical men on women. It is not many years

since the native women of our great Eastern Empire were practically without any skilled medical assistance whatever, that is to say, skilled in the modern scientific sense of the term. That deficiency has been in great part supplied by the Zenana Mission, which supplies qualified lady doctors, who are allowed free access to the native houses. Some interesting facts were given by Lord Kinnaird at the annual meeting of the Zenana Bible and Medical Mission last week in Exeter Hall, London. It appears the Society now has no less than 154 European missionaries, with 270 native Christian teachers and nurses, at thirty-seven centres in India. There is an immense field still open in this direction for solid good work in the relief of suffering humanity, as shown by the fact that in not a few Eastern cities the size of Liverpool there are only one or two medical missionaries available at the present time.

Homes for Inebriates.

THE Annual Report of the "Homes for Inebriates Association" embodies the record of another year's work which, on the whole, is encouraging, in spite of the fact that a smaller number of patients presented themselves for treatment at the Dalrymple Home, at Rickmansworth, during the past year, and there was a loss on the year's working. It is but too obvious that the value of legislation has not been at all commensurate with the condition which it was intended to remedy, but this cannot cause surprise in view of the highly tentative and restricted scope of the law relating to the sequestration of confirmed inebriates. The Act of 1898 only applies to those whose failing has become a public scandal, bringing them within the purview of the criminal law, but it leaves unassisted the thousands of unhappy victims of the alcoholic habit whose vicious practices are tinctured with a measure of discretion so far as publicity is concerned. No doubt when our legislators have had time to satisfy themselves as to the value of the treatment, they will be willing to extend the scope of the law and offer a helping hand to those who cannot be trusted to help themselves, without interposing technical and often insurmountable obstacles. The loss sustained in the person of that indefatigable and consistent temperance advocate and reformer, the late Dr. Norman Kerr, is acknowledged in the report in feeling terms that will commend themselves to those who are cognisant of the immense amount of time and labour which he devoted to the spread of sound temperance principles.

Temperance and Advertisement.

YOUR thorough-going temperance advocate is nothing unless an enthusiast. He proves too much, assumes too much, suggests too much, asserts too much, infers too much; in a word, he is a creature of excess, and so is wont to arouse opposition by the rancour of his over-statements. At Lille, Professor Folet has recently entered the lists with a ponderous anti-alcoholic weapon of his own forging. His task is unhappily light enough so far as the proof of the enormous and increasing consumption of alcohol in

France is concerned. Thus, we are told, that whereas the consumption of absinthe in 1881 was only 18,000 hectolitres, in 1897 the amount had risen to 168,000 hectolitres. Further, the consumption of alcohol per head of the French population now reaches 4·72 litres, as against 2 litres per head some twenty years ago. These figures are capable of proof or disproof, but a similar remark does not apply to a further remark of the learned professor to the effect that out of every 100 consumptive patients in the Paris hospitals in no less than 71 per cent. can their malady be traced to alcohol. That statement is probably far removed from the truth. The fact that a consumptive drinks to excess does not necessarily show that alcohol led to his consumption. Then the professor comes to his panacea, which is to apply the vast resources of modern advertisement to the stamping out of the evils of intemperance. We may therefore look forward to a Paris in which temperance warnings are blazoned forth on hoardings, railway stations, omnibuses, tickets, newspapers, blotting-pads, and the thousand and one advertising agencies familiar to the modern citizen of the world. So mote it be.

Mountain Sickness.

THE pathology of *mal des montagnes* is still wrapped in obscurity. While the group of symptoms comprising lassitude, dyspnoea, headache, and palpitation constitutes a serious barrier to many mountaineers, the etiological factors remain far from clearly ascertained. Mr. Douglas W. Freshfield, in the attractive record of his work among the glaciers of Kangchenjunga, published in the last issue of the *Geographical Journal*, details his experience in relation to this matter:—"Most of us Englishmen and natives felt in various degrees our powers diminished; we experienced an indisposition to exertion, bodily or mental—what Stevenson, writing of the climate of Davos, calls 'an underlying languor of the body'—a slackening of pace and increased breathlessness in going uphill. We suffered most on first reaching an elevation of 15,000 to 16,000 feet; there was no increase in our symptoms on rising over 20,000 feet." Mr. Freshfield commits himself to the opinion that while training and habit and attention to diet will not do away with mountain sickness, they will however, go on reducing its area and its virulence. "Kangchenjunga and its still loftier Nepalese neighbour will one day have a flag on their summits"—in spite of the *mal des montagnes*. Let us hope Mr. Freshfield will himself fulfil his own prophecy.

THE rumour that the authorities of St. Bartholomew's Hospital contemplated the reconstruction of the buildings on another site, is contradicted, although this was hardly necessary, in view of the fact that a quarter of a million sterling has just been expended in the acquisition of additional land for extensions on the land now occupied by Christ's Hospital.

The Licensing Question in Ireland.

A PARLIAMENTARY Return just issued gives the following interesting statistics of the licensed houses in Ireland:—The total number of licenses issued numbered 19,702, divided as follows: Belfast 2,845, Cork 2,414, Dublin 4,952, Dundalk 2,386, Galway 2,766, Kilkenny 2,226, Limerick 3,049, and Londonderry 2,075. There are in Ireland 38 brewers: Belfast 4, Cork 6, Dublin 7, Dundalk 4, Galway 1, Kilkenny 10, and Londonderry 3. To brew all the liquor made 5,978,136 bushels of malt were used, of which 4,754,448 were used in Dublin. Of rice, maize, and other preparations 6,307 cwts. were made use of. Of sugar 9,623 cwts. were used, of which Dublin used only 13 cwts. 3 qrs. Taking the recent census returns we find that in Belfast there is one public-house for every 123 of the inhabitants; in Dublin, 1 for every 59; Cork, 1 for every 38; Londonderry, 1 for every 20; Limerick, 1 for every 15; Galway, Kilkenny, and Dundalk, 1 for every 6. The return shows clearly that in small places and towns like Limerick, Galway, and Kilkenny, where local influence can be brought to bear on the magistrates licenses are freely granted, until in many places in Ireland there is a licensed house for every family in the town. We are no advocates for making men sober by Act of Parliament, but we do object, in the interest of the health of the people, to every house in a village being converted into a tavern. The evil is particularly objectionable in small towns where there is no floating population, and these public-houses live on the promotion of drunkenness in the villagers, who become the victims of their excesses. We think the power of licensing should reside in some central authority who, being independent of all local influence, could refuse all applications for a licence to sell alcoholic stimulants other than those he had good grounds for believing necessary. And we further would suggest that from time to time the police should take samples of the liquors sold, and in case of adulteration being detected more than three times in the same house the licence should be cancelled.

Ping-Pong Teno-Synovitis.

THE ubiquitous game of ping-pong has already been dragged into the lists of adventurous insurance agents as a possible cause of death, and from the columns of a contemporary we learn that it may be also responsible for a less severe form of pathological process. Dr. F. G. Crookshank describes a case in which he found considerable œdema of the lower third of the left leg obscuring the anterior border of the tibia, with pain and general disturbance so great as to suggest the possibility of an acute osteomyelitis in a gentleman æt. 30, of heavy build. The patient was put to bed and appropriate remedies employed. The next day the œdema had in great part subsided, and it was obvious from the creaking and crackling sensations on examination that there was acute teno-synovitis, in connection mainly with the tibialis anticus. The patient attributed his condition to his

daily avocation, which involved much walking, but incidentally another and more material circumstance was elicited—that he had been devoting his evenings with much ardour to ping-pong, and had, moreover, played the game wearing his usual stiff buttoned boots. Truly the possibilities of the insignificant are considerable. Dr. Crookshank considers that until in the fulness of time a costume and footgear appropriate to this national sport is evolved, such cases as this will probably from time to time occur.

Cutaneous Precursors of Cancer.

THE presence of multiple cutaneous angiomas, rapidly increasing in number, is regarded by certain observers as an early sign of what may be called the cancerous diathesis, indeed it has been asserted that their existence justifies the suspicion of malignant growth. Statistics, it is true, do not seem to confirm this view to any great extent, apart from the fact that similar developments are met with in persons who have not manifested any tendency to cancerous degeneration. The features upon which special emphasis is laid from a diagnostic point of view are their sudden appearance and their number. In the subjects of cancer, moreover, the existence of these nævoid formations has coincided with the appearance of other cutaneous manifestations, such as a tendency to pigmentation of the skin and the development of a large number of warty outgrowths. According to certain authors, this pigmentation is particularly characteristic, especially in intestinal cancer. In these cases the surplus pigment is distributed in the form of patches, resembling freckles, from which they can be distinguished by their darker hue, their less regular outline and the fact that they make their appearance in parts of the body where freckling proper does not take place.

The Midwives Bill.

WE learn that there is a not remote possibility that the Midwives Bill will fail to become law during the present session, owing to the encroachments which will be made after Whitsuntide on the time devoted to private Bills and to the opposition to which the Bill has given rise. We wish we could add that there was a corresponding possibility that it would never pass into law in its present form—a form in which it is prejudicial to the best interests of the public. Failure to pass this year would undoubtedly have a beneficial effect upon it, and would prove—if anything would prove—to its promoters that a Bill of such a nature must possess the approval of the medical profession, who alone are capable of forming a correct opinion on its essential clauses. Medical men and medical bodies should seize every opportunity which is possible before June 4th to impress on members of Parliament the inadvisability of allowing the Bill to pass in its present form. We have already drawn, and here again draw, the attention of Members to the injustices that the Bill would inflict on the great maternity hospitals of Ireland, and to the necessity for

opposing it unless the alterations which have been demanded by the Royal College of Physicians are granted.

The Refrigerant Treatment of Soft Chancres.

SOFT chancres are not as a rule very refractory to treatment by the methods usually employed, but healing, nevertheless, is often a slow process. Dr. Brandweiner, of Vienna, claims that healthy granulation can be obtained in two or three days by the application of cold. His method comprises the application twice daily for from three to five minutes of a refrigerating substance, such as chloride of ethyl. The sore is carefully cleansed and dried, and a jet of the ethyl chloride is then allowed to play on it, evaporation being promoted by pumping air on to the surface from the tube of a thermocautery. The treatment is one to be employed with caution, because, if too prolonged or severe, sloughing of the tissues may be caused.

Lay Sanitary Missions.

PROFESSOR A. BOSTOCK HILL, of Birmingham, has recently been dealing with the perplexing but most important relationship of voluntary effort to constituted authority in promoting sanitary reform. He showed that, in spite of all the work hitherto accomplished in connection with sanitary progress, there had been practically no reduction in the terrible waste of infant life. The published rates of infant mortality for England and Wales, except in certain special instances, showed no improvement, and, indeed, in some of our large towns the condition of affairs was worse than at the beginning of the sanitary era. Despite efforts to spread knowledge concerning hygienic matters, the people whom it is most essential to teach are not reached. Dr. Hill contends that the only real way of imparting the necessary information was by what he termed "missionary effort" in the homes of the people themselves.

Tobacco Catarrh.

THAT common ailment, cold in the head, represents a group of symptoms common to several very different conditions. The most prominent symptom, nasal catarrh, with more or less obstruction of nasal breathing and running at the nose, is associated in most instances with a disagreeable feeling of tension in the forehead due to implication of the ethmoidal and frontal sinuses. Sometimes, as in hay fever, the affection is dependent upon the presence of a special micro-organism; it is much more frequently caused by an extension upwards of gastric catarrh, which first gives rise to catarrh of the pharynx with dryness and soreness of the throat, and then attacks the mucous membrane of the posterior nares. Attacks presenting this sequence are invariably of gastric origin, and should be treated accordingly. There can be no doubt that a proneness to naso-pharyngeal catarrh is established by the habit of tobacco smoking, especially in the form of cigarettes. In sensitive subjects the smoke provokes a condition of chronic

irritation which is fanned into a flame by comparatively slight exposure. Persons addicted to habitual cigarette smoking, it will be noticed, complain of huskiness, and the voice has a muffled tone due to engorgement of the mucous membranes. When the smoke is inhaled there is in addition a troublesome short dry cough, testifying to chronic irritation of the larynx. Such cases are very refractory to treatment, because the sufferer is rarely willing to consent to the removal of the source of irritation.

Small-pox in London.

THERE has been no marked diminution in the outbreak of small-pox in the metropolis, but the negative fact of there being no serious increase in the month of May renders the outlook more hopeful. The number of patients under treatment at the Metropolitan Board's Hospitals on Friday, May 2nd, was 1,452, a slight decrease on the figures of the preceding week. Taking the two weeks together there were 1,474 cases, as against 1,458 for the previous fortnight. The deaths from small-pox in London were 42 for the past week, compared with 54, 78, and 42 in the preceding three weeks. It is therefore evident that the disease is about stationary, which is so far the best news that could be looked for at this time of year. One of the most noteworthy incidents of the week with regard to the epidemic has been the prosecution of a Croydon resident for refusing to permit the removal of his son, a small-pox patient, to the local infectious hospital. The father, who was fined £5 and costs for this offence, contracted the disease himself. His wife was fined £3 and costs for refusing to allow her husband to be removed. The local authority can interfere only when a householder is not able to carry out proper isolation, or where the safety of other persons, as in an hotel, would be obviously endangered. Prosecutions of this nature are fortunately rare, and would naturally be avoided by the sanitary authorities unless in extreme cases.

Hospital-mongering in the United States.

As all the world knows, medical advertising is carried on in a perfectly open and unabashed manner in the United States. A somewhat lurid example of the way in which some of the obscurer so-called medical charities are managed in that country may be gathered from an account recently published in the *Morning Leader*. That journal states that St. Luke's Hospital, of Niles, Michigan, a town of 6,000 inhabitants, offers the following advantages to gentlemen wishing to join their dental staff:—(1) A neat lithograph pocket membership ticket costing two dollars, which, judiciously displayed, should pay for costs of dental certificate many times over in a single year. (2) A very costly and ornamental solid gold button with inscription, costing two dollars also. (3) A commission of 25 per cent. cash for all surgical and 10 per cent. for all medical cases sent to the hospital. (4) A certificate from fifteen to twenty-five dollars, according to style and language. The candour of these induc-

ments, supposing them to be genuine, shows a keen commercial grasp of the situation. It is hard, however, to imagine how solid gold buttons can be produced and sold at a profit at the price quoted by this enterprising hospital. The state of Michigan must be governed by a complacent set of rulers if they allow private institutions to confer qualifications at their own sweet will in the manner indicated in the foregoing sketch. If we remember aright, not a few of the quack testimonials published on this side of the Atlantic are supported by the familiar title of "M.D. Mich., U.S.A."

Ratepaid Revaccination.

ALTHOUGH technically the services of the public vaccinator are at the disposal of all and sundry, irrespective of social status, most people in a position to pay for medical attendance prefer to have recourse to a private practitioner for revaccination. Such does not appear to be the view of the Chief Constable of Flintshire, who sees no harm in having his family and himself revaccinated at the public expense, a fact to which exception was taken by certain members of the Holywell Board of Guardians. In a letter addressed to the Board the Chief Constable affirms his undoubted right to be vaccinated at the cost of the rates, "to which he has paid for years and from which he has derived no personal benefit." We would call the gallant major's attention to the fact that free vaccination is not the sole purpose to which rates are applied, and we would respectfully point out to him that if all the inhabitants followed his example the rates would undergo a very marked increase; indeed, in his own district the additional cost has been calculated at not less than £11,000.

Test for Albumin.

A SIMPLE test for albumin in the urine is suggested by F. C. Fuhs (*Med. Rec.* Mar. 8th, 1902). Equal parts of carbolic acid and glycerine are used and an equal quantity of urine is added. The mixture is then shaken and an emulsion formed. If there is any albumin present in the urine a turbidity appears which, it is said, is always due to the albumin and will not be formed by the presence of any other excrementary substance. The test is very sensitive, for 0.1 per cent. of albumin can easily be detected. Glycerine is used to prevent the formation of a permanent emulsion between the carbolic acid and the watery elements of the urine and is added in excess to prevent any possible error.

Sanitary Works at Buckingham Palace.

WE understand that the drainage and other sanitary arrangements which were carried out at Buckingham Palace by the officials of his Majesty's Office of Works a few years ago have been thoroughly inspected and tested by Professor Corfield, M.D., the Consulting Sanitary Adviser to H.M. Office of Works, who has reported "that the drainage arrangements have been very well planned and carried out, and reflect credit on all concerned with them." He has,

however, suggested a number of improvements in the sanitary arrangements generally, the most important of which have been already carried out under his supervision and to his satisfaction. The remainder, which consist chiefly of certain re-arrangements, will be carried out in the autumn.

The Proposed Disruption of Victoria University.

IN consequence of the decision of Convocation against disruption the graduates of Victoria University are taking very practical steps to carry out the wishes of Convocation. A petition is being prepared, and is to be presented to the Privy Council. Public opinion and the best educational opinion does not favour a multiplication of local and necessarily feeble and narrow-minded Universities in this country. As the numerous medical graduates scattered throughout the country recognise that disintegration of the Victoria University will lower the value of the degree and tend to weaken the standard of medical education, the petition will doubtless receive influential support.

The Gonzaga Panacea.

A LEADING article in one of the daily papers was recently devoted to an account of the wonderful properties of a panacea which renders all who drink of it immune, not only to small-pox, but every other kind of contagious disease. The preparation is not a culture of the bacilli of small-pox or any other known zymotic disease, but is simply an admixture of well-known drugs. It is as follows:—Sulphate of zinc, one grain; solid extract of digitalis, one grain; one half-teaspoonful of sugar. Mix all with two tablespoonfuls of water; when thoroughly mixed add four ounces of water. Taken, teaspoonful every hour for twelve hours; for a young child diminish the dose. This remedy will cure scarlet fever, as well as small-pox and diphtheria. This absurd prescription emanates from Mother Gonzaga, of the Nuns of St. Joseph, Philadelphia. We do not suppose for one moment that Mother Gonzaga had any other motive in publishing her formula than to benefit the public. But any ordinary intelligent woman, recognising that she knew nothing of the cause, character, or treatment of disease, would have submitted the remedy to some physician of standing in his profession before launching it on the world with absurd, groundless, and fallacious claims. But what is to be said of those who use the formula and prepare the mixture as a trade advertisement? We would like to know on what grounds a vendor of this worthless nostrum would defend himself, in case that a child suffering from diphtheria died whilst under Mother Gonzaga's treatment.

It is announced that thirty commissions as surgeons in the Royal Navy will be offered for competition early next month. Twelve commissions in the Indian Medical Service will be offered at an examination to be held early in September.

An Interesting Case.

At a recent meeting of the Academy of Medicine of Paris MM. Chipault and Lefur read the clinical history of an interesting case of a man who, without any appreciable affection of either the nervous system or of his viscera, suffered atrocious abdominal pains for years. During these paroxysms of pain, which were most intense at the navel, the body was strongly flexed, and the abdominal muscles contracted violently. The hyperalgesic region corresponded to the area of distribution of the eighth, ninth, and tenth dorsal ribs. Hypodermic injections having given no good results, spinal injections were tried, and they also failed. It was now decided to cut the intercostal nerves of the area of greatest pain, and this was done without any benefit. The posterior laminae of the eighth, ninth, and tenth dorsal vertebrae were then incised, and the posterior roots of the corresponding spinal nerves cut. When the spinal cord was exposed there was found a localised patch of arachnitis of some standing. The result was eminently satisfactory. At the end of a month the hyperalgesic zone had disappeared, and gradually the severity of the paroxysms of pain diminished until they finally ceased. The operation and the pathological condition both have an interest for British surgeons. That the operation was feasible was demonstrated by John Bell, who instructed his younger brother in its performance and in the physiology of the nerve roots; and the paroxysmal pains were described long since by Dr. William Griffin.

Pigmented Moles and their Clinical Significance.

It is an open question whether the cells of which pigmented moles are composed are derived from epithelium, or have a mesodermal origin. Unna favours an epithelial origin, and his view has been confirmed by other investigators, but clinically it is admitted that malignant growths starting from naevi partake of a sarcomatous, rather than of a carcinomatous, character. Leaving this purely academic question for further study, the importance of moles as the starting-point of intensely malignant and pigmented growths cannot be too strongly insisted upon. The great thing to bear in mind is that the slightest sign of growth in a pigmented mole is an indication for immediate and thorough removal. Any operation which falls short of free ablation is a mistake not unlikely to be attended by serious consequences, for there lurks in the cells of pigmented moles a malignant potency too generally overlooked.

THE annual general meeting of the Medical Defence Union will take place on Thursday, May 15th at 5 p.m., at 4, Trafalgar Square, to receive the annual report and to transact the business of the association. That of the London and Counties' Medical Protection Society is to be held at the offices, 31, Craven Street, Strand, on the 8th inst.

Eggs as a Medium for the Cultivation of Bacillus Tuberculosis.

It seems that the egg affords an excellent medium for the cultivation of the tubercle bacillus, a circumstance which might excite apprehension were the contents of the egg not hermetically closed against contamination from the outside. According to Dr. Dorset (a) the egg may be used as whole, i.e., white and yolk mixed, or the yolk and white may be employed separately. The former gave the most satisfactory results, but he was enabled to grow colonies in all three. Hitherto the cultivation of the tubercle bacillus upon artificial media has been found a matter of extreme difficulty, especially when the cultures were attempted with bacilli drawn from animal tissues. The effect of the egg medium upon the morphology and virulence of the several varieties of tubercle bacilli has not been determined, but the ease with which these cultures can be made will, the author suggests, be of value to those engaged in experimental work in connection with this organism.

WE are informed that eighteen students have entered for the current session of the London School of Tropical Medicine, among them being several members of the Colonial Services and two ladies.

PERSONAL.

DR. A. BROWN RITCHIE has been appointed Medical Officer to the School Board for Manchester.

SIR WILLIAM SELBY CHURCH has had conferred upon him *honoris causa* the degree of D.C.L. of the University of Durham.

SIR JOHN ANDERSON, K.C.M.G., is to take the chair at the May dinner of the Aberdeen University Club, which will be given on the 21st instant.

HIS GRACE THE DUKE OF ARGYLL will preside at the dinner of the Edinburgh University Club, which takes place at the Criterion Restaurant this (Wednesday) evening.

PROFESSOR WILLIAM R. SMITH, of King's College, has been awarded the Harben Gold Medal of the Royal Institute of Public Health, in recognition of his services to public health.

A GENEROUS but anonymous donor has sent one thousand pounds to the Treasurer of Guy's Hospital, under the initials "J. M.," towards the renovation and building fund of the hospital.

DR. VERNON GREENHOUGH, of Chapel-en-le-Frith, was the victim a few days since of a serious carriage accident, he having been pitched down a steep embankment owing to his horse having been startled by a dog.

DR. WHEATLEY, Medical Officer of Health of Blackburn, was presented last week with a silver fruit dish and other articles of plate by the members of the

(a) *American Medicine*, April 5th, 1902.

Borough Police Force, of which he was until lately surgeon.

DR. W. A. REIDY and his brother, Dr. Charles Reidy, of Maes-y-cwimmer, have been presented with illuminated addresses and cases of surgical instruments in recognition of their behaviour in connection with the Maes-y-cwimmer shooting case.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

PROPOSED ALTERATION IN THE MEDICAL CURRICULUM OF THE UNIVERSITY OF EDINBURGH.

IN the joint reports of the business and finance committees at the forthcoming half-yearly meeting of the Council an important item dealing with the curriculum of the medical student will come up for consideration. The committee recommends the Council to pass the motion by Drs. Richard Berry and Norman Walker—"That this Council requests the University Court to inquire into the feasibility of reorganising the medical curriculum on the lines suggested by the Pathological Club of Edinburgh." The report continues:—"Only a few years ago the medical curriculum was altered, and a fifth year was added, with a view to give the student in the end of his course more time for the clinical subjects, which are the completion of his equipment for entering the practice of his profession. This expectation has entirely failed. These latter sessions are as crowded as ever, and the additional year and extra expense give the medical student no relief. Concurrently with this, the increased attention to hospital teaching has resulted in the hours from 11 to 1 being given over absolutely to clinics. Hence the pressure upon, and friction with regard to the other hours available for systematic lectures have led to the present arrangements being further closely scrutinised. It was in this way that the scheme came to be drawn up, and its elaborate detail about hours is thus to be explained. The framers, however, claim, and your committee think with reason, that the scheme does more than offer a solution of this question of the hours, and that it also formulates a plan for the distribution of the time and energy of the medical student throughout his whole course which is well adapted to present requirements, and not as a balance, meantime sadly lacking, among the numerous subjects. . . the scheme makes the following proposals:—The academic year shall be divided into three terms of ten or eleven weeks each, all the alteration made in the existing periods being that all the classes, and not anatomy only, would meet on October 1st. All examinations shall be held thrice a year, and, unless under strict regulations, no student who has failed to pass an examination shall be allowed to attend the succeeding classes of the course. The order in which students may take out their classes is to be prescribed, so that they may proceed logically with their studies, and the subjects may be grouped in a rational sequence. . . Dr. Berry's scheme was widely commented on in the medical journals at the time of its publication some eight or nine months ago, and it is a matter for congratulation that it has now been formally considered and approved by the University Council. It is a far cry from this, however, to its actual adoption by the University. One can only hope.

LABORATORY OF THE SCOTTISH ASYLUMS.

The fifth annual report has recently been issued, and contains a gratifying record of steady progress. Dr. W. F. Robertson, the pathologist, states that a great deal of time has been occupied with the special study of material sent to the laboratory from asylums for special report, work which had, for various reasons, fallen somewhat into arrear, but is now practically up to date. Twenty-seven cases were reported upon during the year.

Eight workers have carried out independent researches upon such subjects as the intra-cranial lymphatic system, general vascular and cerebral capillary changes in paralytic dementia, morbid anatomy of Mongolian idiocy, tabes dorsalis, and certain forms of nervous disease in horses, and the pathogenesis of paralytic dementia. Arrangements are being made by which bacteriological observations may be carried out upon cases of insanity by workers connected with the laboratory. It is thus hoped that some definite progress will be made in research upon the acute insanities. The General Board of Commissioners in Lunacy heartily commend the laboratory, and express the opinion that so far from the erection of a central laboratory having suppressed scientific research in the individual asylums, opportunities for prosecuting such work have been facilitated by the training of the assistant medical officers of the asylums in methods, the circulation of "demonstration sets" of slides, and the collection of a reference and lending library. During the first four years of the laboratory's existence twenty-four assistant medical officers of asylums and six other medical men received instruction in laboratory work. Twenty-six demonstration sets were circulated 124 times, five special memoranda were issued, and 152 issues made from the lending library. There are probably few laboratories in the kingdom in which more honest scientific work is done than in this of the Scottish asylums, and it is not too much to say that nine-tenths of its success have been due to the zeal and industry of the pathologist who has done so much with such a modest establishment.

Belfast.

[FROM OUR OWN CORRESPONDENT.]

THE APPROACHING ELECTION TO THE SENATE OF THE ROYAL UNIVERSITY.

THE chief topic of conversation in medical circles in Belfast during the past week has been the approaching election of six representatives of Convocation on the Senate of the Royal University, and the manifesto of the Royal University Graduates' Association thereon, published as a letter from one of the secretaries of the Association in the Belfast papers of May 2nd. The six retiring members are Dr. J. W. Browne, Mr. E. Cuming, Rev. Dr. Leitch, Judge Shaw, Professor Sinclair, and Sir Wm. Thompson, all of whom offer themselves for re-election. Three other candidates have appeared—Dr. Cotter, of Cork; Mr. Michael Drummond, K.C., of Dublin; and Mr. Anderson, President of Queen's College, Galway. The above-mentioned letter quotes from a circular marked "confidential," said to have been sent to the Roman Catholic members of Convocation, calling on them to plump for Dr. Cotter and Mr. Drummond, and goes on to call on members of the Association to vote for the first five of the retiring members, but to substitute Mr. Anderson's name for Sir William Thompson. The reason of this attack on Sir William is stated to be his attitude towards the vexed question of the appointment of extern examiners in the Royal University. The Royal University Graduates' Association—more familiarly and briefly known in Belfast as "Dr. McKeown's Association"—is said to number about 500 members, of whom nearly half are members of Convocation, so that if they all do as their militant leaders bid them, they will exercise a considerable influence on the poll. The Association is composed of admirers of the Royal University, who admit that it is not in robust health, but think that a course of mild tonics and alternatives (such as extern examiners) will make it a thing of beauty and a joy for ever. There is a large number of outsiders, however, including probably the majority of medical men holding hospital appointments in Belfast, who refuse to have anything to do with the Association. They believe that the Royal University was conceived in iniquity, brought forth in sorrow, and has been a

malformed monster from its earliest days, and while some say that an extensive operation might effect a radical cure of its more objectionable deformities, others think that euthanasia and a quiet grave would be more satisfactory in the long run.

In the point at issue, however, many of these outsiders will undoubtedly agree with the Association, the feeling that the Belfast Medical School has been unfairly treated by Dublin being deep and widespread.

NATALITY IN GREAT BRITAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—This important and most interesting subject has clearly many aspects, as shown by the different standpoints from which your correspondents have dealt with it. "A Student of Medicine" invites the opinion of the practical physician, and especially the gynaecologist, and I propose to make a few observations on this part of the subject. Before doing so, however, I should like to say a few words on the wider question of the ethics of this department of Malthusianism.

I apprehend that the advocates of the practice of preventing conception contend that the limitation of the number of children is a measure of prudence; as a matter of fact, I entirely agree with "A Student of Medicine," that the effect on the moral and mental health of both husband and wife is that selfishness is directly engendered, and that the good qualities developed by conscientious fatherhood and motherhood are inhibited. Moreover, in practice, the thriftless and improvident couples are usually the ones that let families multiply apace, whilst those who do adopt preventive measures are mostly the people in somewhat better circumstances and of a fair degree of intelligence; these people could almost invariably make provision for the increased financial responsibility involved, and their children, if they had any, would probably be of a type of mental development which is of the greatest service to the community.

My experience leads me to believe that in many cases the deliberate prevention of conception in the early years of married life is followed later on by unhappiness and mutual recriminations; for the instinct of fatherhood or motherhood which is at first latent may become developed when the opportunity would appear to have passed away. On the other hand, when one or more children have been born to couples who perhaps at first felt grave anxieties as to their financial prospects, there seems to be good reason to believe that they have almost invariably managed, perhaps with the exercise of a not unwholesome self-denial, to make a proper provision for the new-comers.

Speaking generally, therefore, the rule of wisdom appears to be to let events take their natural course.

I am far from urging that there are no cases where preventive measures should be adopted. There are cases where a family has attained a certain size, and where special circumstances make it undesirable for the parents and unfair to the existing children that the numbers should be indefinitely increased. There are cases where the woman's health imperatively demands that she should not incur the additional risks of child-bearing, either for a given period or at any time; and lastly, there are instances where the husband or the wife, or both, may be suffering from some disease that will necessarily lead to disease in their children, and in these cases it appears to me that the argument for preventing conception may be a sound one.

I come now to the question specially raised by "A Student of Medicine," namely, the effect on the physical health, and especially the pelvic organs, of women who,

while gratifying their sexual appetites, adopt systematically effective means to prevent conception. It must be admitted at the outset that the question is by no means an easy one, because a direct relation of cause and effect is often very difficult to trace. An experience of many years of gynaecological practice in hospital and in private supports the view that patients who have had many years of childless marriage show a special tendency to functional disorders associated with pelvic congestion, and leading to leucorrhœa, fulness and weight in the pelvis, backache, and chronic lack of energy. From this class also the ranks of neurasthenic women are largely recruited. Moreover, it is a fact that the mothers of moderate and large families hardly ever suffer from uterine fibro-myoma, and that, on the other hand, this condition when occurring in married women is nearly always associated with a long period of sterility; and it is by no means uncommon among single women. It may, of course, be argued that the tendency to fibro-myoma of the uterus is the cause and not the consequence of the sterility; but the view that the sterility is a causal factor is not without support, especially in view of cases where no sign of the disease has appeared until after many years of sterility. Hence the view is permissible that the development of fibro-myoma is, speaking figuratively, Nature's protest against the disappointed natural function of the uterus, namely, pregnancy. It is possible that the periodic congestion incidental to menstruation leads to pathological hyperplasia and fibrotic changes, in the absence of that respite from menstrual activity which successive periods of pregnancy and lactation afford.

These observations are made in the tentative spirit demanded by the scientific uncertainties of the subject, but no doubt it is a sound generalisation that the fulfilment of the natural functions of organs is more likely to be associated with health than their non-fulfilment.

I am, Sir, yours truly,

London, May 1st, 1902.

GYNÆCOLOGIST.

Medical News.

The Investigation of Cancer.

THE Worshipful Company of Drapers have voted a sum of £250, to be paid in five annual instalments of £50, towards the fund of the Middlesex Hospital for the scientific investigation of the cause and cure of cancer, on the understanding that the hospital's Director of Research shall present year by year to the Presidents of the Royal College of Surgeons and the Royal College of Physicians a report of the work done in the laboratories by himself and his assistants, and on condition that this work is duly approved and the Presidents consider the object worthy of support.

Merck's Annual.

THE fifteenth volume of the valuable Annual Reports issued by the well-known house of E. Merck, of Darmstadt, has just appeared. The medical profession owe much to the enterprise and research of pharmacists, and this work is such as to place all medical men under a debt of gratitude. All new and sufficiently important pharmaceutical preparations are reviewed in an impartial spirit, and there is no evidence of those objectionable features only too frequently visible in ordinary market and drug reports of many firms. We advise every medical man to procure a copy of this annual, as it will prove of much service for purposes of ready reference, and affords much material rich in suggestions.

Apothecaries Hall of Ireland.

At the quarterly meeting of the Governors and Company of the Apothecaries Hall, held on May 1st, it was proposed by Dr. J. McWalter, M.A., seconded by Dr. J. Evans, and passed unanimously:—"That, in the opinion of this Company, the action of the Institute of Chemistry in examining candidates in therapeutics and issuing certificates of qualification in that subject constitutes an infringement on the rights of the medical profession, and that our representative in the General Medical Council be requested to ascertain the legality of the practice."

Cork Fever Hospital.

At the annual meeting of this institution held last week the report of the medical staff stated that the total number of cases treated was 228. Typhus, 8 cases—no death occurred from this disease; enteric, 36, of whom 2 died; scarlatina, 145, of whom 5 died; diphtheria, 6, all of whom recovered; erysipelas, 9 cases, with 1 death; pneumonia, 9 cases, with 1 death. The percentage of mortality from every cause 4.3. There were no cases of small-pox. After the adoption of the report, and some further resolutions, the meeting terminated.

Suicide of a Lady Doctor.

MISS JEANIE M'LEOD, daughter of Mr. Alfred M'Leod, Lecturer on Elocution at Aberdeen University, was found dead in bed on Friday morning with her throat cut. She took her medical degree last month, and had just been appointed resident physician to the Aberdeen Sick Children's Hospital. She was one of the most distinguished women medical students Aberdeen University has produced.

Middlesex Hospital.

THE GOVERNORS of the Middlesex Hospital have received a further donation of £500 from Sir Elliott Lees, Bart., M.P., half of which has been allocated towards the maintenance of the inmates of the wards in the special department devoted to incurable cancer patients, and the other half to the research department established in connection with it for investigation into the cause of that malady.

The Medical Labourer's Hire.

At the hearing of a judgment summons at the Lambeth County Court the other day it was stated that the defendant, a fully qualified medical man, was acting as assistant at a weekly wage of fifteen shillings, with board and lodging. Out of this he will have to find the means to pay his tailor's bill, otherwise he is threatened with "seven days."

University of Durham.—Faculty of Medicine.

At the Convocation holden on Saturday, April 26th, 1902, the following degrees were conferred, viz.:—

Doctor in Medicine.—Laurence J. Blandford, M.B., B.S., Durh., Leopold S. Davison, M.B., B.S., Durh., Richard H. Dix, M.B., B.S., Durh., Henry A. Fielden, M.B., B.S., Durh., John R. Fuller, M.B., B.S., Durh., Edward W. Joscelyne, M.B., Durh., Eliot Swainston, M.B., B.S., Durh., David H. Weir, M.B., B.S., Durh.

Doctor in Medicine for Practitioners of Fifteen Years' Standing.—Edward H. Armitage, M.B.C.S., L.R.C.P., D.P.H., Charles W. J. Bell, M.R.C.S., L.R.C.P., E., Albert Bowhay, M.R.C.S., L.R.C.P., L.S.A., D.P.H., Edward J. Day, M.B.C.S., L.S.A., Ambrose W. Fairless, M.R.C.S., Thomas F. Gardner, M.R.C.S., M.R.C.P., L.S.A., Frederick C. Goodwin, M.B.C.S., L.R.C.P., D.P.H., William Gosse, M.R.C.S., L.R.C.P., Robert E. Hunter, M.B., M.S., Glas., M.R.C.S., Richard J. Morris, M.R.C.S., L.R.C.P., L.S.A., John L. Parke, L.K.Q.C.P., L.F.P.S., G., L.S.A., D.P.H., James W. Patrick, L.R.C.P. and S., George F. Pollard, M.R.C.S., L.S.A., Alfred T. Rimell, M.B.C.S., L.R.C.P., John Rogerson, L.R.C.P. and S., E., L.F.P.S., G.

Master in Surgery.—Joseph W. Leech, M.D., B.S., F.R.C.S., E., William H. Richards, M.B., B.S.

Bachelor in Medicine (M.B.).—Ernest B. Appleby, William R. D. Daglish, Mary E. De Russett, Henry W. Furnivall, James A. Giles, James H. Graham, Ivon H. S. Hawes, Kenred Manson, Lucy S. Molony, Robert W. Nevin, Henry Reah, Ralph S. Renton, Hermann H. Ruffmann, Alfred H. Proctor, Godfrey De Bec Turtle, Ralph T. Vaux, Marmaduke C. Wetherell, Hugh Widdas, Thomas Wilson.

Bachelor in Surgery (B.S.).—Ernest B. Appleby, William R. D. Daglish, Mary E. De Russett, Henry W. Furnivall, James A. Giles, James H. Graham, Ivon H. S. Hawes, Kenred Manson, Lucy S. Molony, Robert W. Nevin, Alfred H. Proctor, Henry Reah, Ralph S. Renton, Hermann H. Ruffmann, Godfrey De Bec Turtle, Ralph T. Vaux, Marmaduke C. Wetherell, Hugh Widdas, Thomas Wilson.

The Diploma in Public Health (D.P.H.).—Charles V.

Dingle, M.D., B.S., B.Hy.; Robert A. Dunn, M.D., B.S., D.Hy. Durh., M.R.C.S., L.R.C.P.; Alfred Reid, M.R.C.S., L.R.C.P.; Robert Walker, M.B. B.S. Durh., M.R.C.S., L.R.C.P.

Royal University of Ireland.

M.B., B.Ch., B.A.O. DEGREES EXAMINATION.—The following candidates have passed the above-mentioned examination:—

Upper Pass.—*John Armstrong, *Albert L. Black, B.A., Samuel R. Hunter, B.A., *Walter Phillips, B.A., Charles F. White.

Those marked with an asterisk (*) may present themselves for the further examination for honours.

Pass.—David R. Campbell, B.A., John Clements, Timothy F. Heas, John P. Higgins, M.A., John L. Lunham, Maurice J. Macauley, Francis H. McCaughey, Edward J. McKenna, Frederick C. Mann, Louis T. Moore, William F. O'Connor, Patrick O'Doherty, John J. O'Hare, Frederick W. Stewart, B.A., William A. Stoops, B.A., William J. Thompson.

THIRD MEDICAL EXAMINATION, 1902, SPRING.—The Examiners have recommended that the following candidates be adjudged to have passed the above-mentioned examination:—

Upper Pass.—Thomas Barry, William M. Crofton, B.A., Hugh P. Devlin, William Egan, Robert Johnston, Denis J. Keane, Samuel H. Whyte, Malcolm O. Wilson. The above candidates may all present themselves at the further examination for honours.

Pass.—Anna E. Adderley, Robert J. Cahill, Foster Coates, B.A., William H. Davis, John Dawson, Edward Fitzgerald, Arthur S. Gardiner, Devonshire P. H. Gardiner, Mary K. Gibson, Harry Gill, Samuel J. Killen, Francis McDonald, John W. McFarland, Robert H. McGiffin, Francis A. McOstrich, George B. Moffatt, Edward J. O'Hanlon, John S. O'Neill, Patrick Quinn, John G. Shanklin.

Conjoint Examinations of the Royal College of Physicians and Royal College of Surgeons.

The following candidates have passed the Second and Third Professional Examinations:—

Second Professional (Old Regulations).—W. H. Bourne.

Second Professional (New Regulations): A. Honours in Order of Merit.—J. Bradley, J. J. Connolly, Miss A. M. Barry, Miss J. C. Hargrave, J. Pratt, M. Lochrin; J. C. Murphy, J. Sheill (equal); J. C. Heelon, E. C. Mulligan. B. Pass, Alphabetically.—E. B. Bird, A. J. Bracken, G. P. A. Bracken, A. N. Crawford, C. A. Cusack, F. O'D. Fawcett, P. E. Harrison, G. A. D. Harvey, R. W. D. Leslie, T. C. C. Leslie, W. F. B. Loughnan, T. J. O'Donnell, E. J. Phillips, J. Quirke, R. E. J. Sheridan, W. J. Sullivan. C. Completed the Exam.—P. Kinsella, T. B. Moriarty.

Third Professional: A. All Subjects.—P. McDermott, R. C. Nicholl, J. P. Ziervogel. B. Completed Exam.—F. H. Cooke, E. Humfrey, J. Murray, O. F. M. Ormsby, R. F. H. Oulton, F. C. Yorke.

Conjoint Board for Scotland.

At the April meetings of the Scottish Conjoint Board of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, held in Glasgow, the following candidates passed the respective examinations as undernoted:—

First Examination, five years' course.—Fred Miller Murray, Frederick Barnes Elwood, Andrew Ford Garrand, John Wm. Nelson Roberts, Frederic James Breakell, Evan Alan S. Shaw, Edward Francis Nyhan.

First Examination, four years' course.—John Stothart Farrier, Alexander Jack, George Munro MacLeod.

Second Examination, four years' course.—Adam Ardill, Joseph Edmund Mullan.

Final Examination (and admitted Licentiate of the three Co-operating Colleges).—Henry Leighton Jones, Thomas Weir McCubbin, William Thomson, Edwin Norman de Vere Dawson, Henry Solomon, Stanley Lister, G. D. MacLaine, William Henry Duncan, Hugh Williams, Terence Aloysius Welch Patrick Carroll.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

THE SALE OF BROMIDIA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It was stated at the inquest on the late Mr. Geoghegan that he had become possessed of an entire bottle of bromidia, a statement which is calculated to give rise to a very erroneous impression concerning this extensively prescribed medicament.

As agents for Messrs. Battle we desire to point out that bromidia is not in any sense a secret preparation, the complete formula being freely communicated to the medical profession in the literature bearing thereon. Nor is bromidia a "popular remedy," for it is not intended to be supplied to the public otherwise than in accordance with a physician's prescription, like any other active pharmaceutical product.

The bottles containing it only bear the plain bromidia label with the dose, and neither on the label nor on the wrapper is any indication given of its nature and use.

The paper envelope bears a label specially calling attention to the fact that the preparation is supplied unstamped for dispensing purposes.

Yours, Sir, yours truly,

ROBERTS AND CO.

76, New Bond Street.

[It would be interesting to know whether the bottle supplied to the victim was stamped in accordance with the law, and under what circumstances so large a quantity was supplied, presumably without a medical prescription.—Ed.]

L.R.C.P.—Your letter on "The Vagaries of Medical Etiquette" is unsolicited for publication.

DR. F. N. C. (Birmingham).—We have referred our correspondent's note to the writer of the article, "The Electrical Treatment of Pulmonary Phthisis."

ASSISTANT.—The cause which has led to the friction described appears to us to be one which our correspondent could himself easily remove without loss of dignity.

MEDICO.—The district has grown rapidly of late years, the train service, for a suburb, being excellent. The class of houses is good, and quite possibly a new-comer might find an opening.

DR. F. H. Y.—The allegation if untrue, is, in our opinion distinctly libellous.

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, MAY 7TH.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.)—8 p.m. Specimens will be shown by Mr. Alban Doran, Dr. McCann, Dr. Ralph Vincent, and others. Paper—Dr. John S. Fairbairn: Five Specimens of Fibroid Tumour of the Ovary, with Observations on their Pathological Anatomy.

THURSDAY, MAY 8TH.

BRITISH GYNECOLOGICAL SOCIETY (20, Hanover Square, W.)—8 p.m. Dr. Bedford Fenwick: Fifty Laparotomies. Specimens will be shown by Dr. A. J. Smith, Dr. H. Macnaughton-Jones, and others.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.)—8.30 p.m. Discussion on "The Early Diagnosis of Specific Fevers." Opened by Dr. Sidney P. Phillips.

FRIDAY, MAY 9TH.

THE BRITISH LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL ASSOCIATION (11, Chandos Street, W.) General Meeting. Cases will be shown by Dr. Wyatt Wingrave, Mr. Mayo Collier, and Dr. Abercrombie. Adjourned discussion on "The Diagnosis and Treatment of Various Forms of Nerve Deafness."

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.)—8.30 p.m. Mr. W. G. Spencer: Congenital Diffuse Lymphangioma terminating in Lymphosarcoma in a Child aged 4 years. Mr. George Turner: Sarcoma of the Ankle-Joint. Mr. C. B. Lockwood: Sarcoma of the Synovial Membrane. Dr. W. Ewart and Dr. Isambard Owen: A Case Illustrating the Clinical Features of "Horizontal" Dilatation of the Left Auricle. Dr. Isambard Owen: "Horizontal" Dilatation of the Left Auricle. Dr. W. Ewart: A Note on Palpable Systolic Intercostal Pulsation in a Case of Mitral Stenosis, with Dilatation and Thrombosis of the Left Auricle.

POST GRADUATE COURSES AND LECTURES (Medical Graduates' College and Polyclinic, 22, Chancery Street, W.C.)—Demonstrations will be given at 4 p.m. as follows:—Monday, Skin; Tuesday, Medical; Wednesday, Surgical; Thursday, Surgical; Friday, Eye.

WESTMINSTER HOSPITAL.—On Tuesday May 13th Dr. Allchin will give a Demonstration in the Post Graduate Clinical Course on "Some Clinical Aspects of Arthritis" at 4.30 p.m.

DUBLIN.

THURSDAY, MAY 8TH.

ROYAL COLLEGE OF SURGEONS.—Council Meeting.

FRIDAY, MAY 9TH.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Surgery, College of Surgeons, 8.30 p.m.

Appointments.

BROUGE, DANIEL, M.B., C.M. Edin., L.R.C.P. Lond., M.B.C.S., Deputy Medical Officer of Health for the Borough of Devonport.

BROWN, H., M.B., Ch.B. Vict., Resident Obstetric Officer to the General Infirmary, Leeds.

CLARKSON, W., L.R.C.P. Edin., L.F.P.S. Glasg., Medical Officer of Health to the Morpeth District Council.

DODGSON, H., M.B., Ch.B. Edin., Senior Assistant Medical Officer to the Cumberland and Westmorland Asylum.

ELDER, J. B., M.B., Ch.B. Aberd., Junior Assistant Medical Officer to the Cumberland and Westmorland Asylum.

HINGTON, CHARLES ALBERT, M.D., B.Sc. Lond., M.B.C.S., Honorary Physician to the Crownhill Convalescent Home, near Plymouth.

JONES, HERBERT, L.R.C.S. Irel., L.S.A., Medical Officer of Health for the Bromyard Urban District.

LAIRD, ANDREW J., M.D., D.P.H., Assistant Medical Officer of Health for the County of Lanark, Medical Officer of Health for the Borough of Crewe.

LEWARCHAND, ARTHUR WHARTON, L.R.C.P. Lond., M.B.C.S., Honorary Medical Officer to the North Devon Infirmary, Barnstaple.

MELLAND, CHARLES HERBERT, M.D. Lond., M.B.C.P., Honorary Physician to the Ancoats Hospital, Manchester.

STEVENSON, ROBERT, M.D., Medical Officer of Health to the Bootle Postal District.

TIPPETT, SYDNEY G., M.B. Lond., Assistant Surgeon to St. Bartholomew's Hospital, Chatham.

WALLACE, J. SIM, M.D., D.Sc., L.D.S. Eng., Honorary Dental Surgeon to the West End Hospital for Diseases of the Nervous System.

Vacancies.

Borough of Weymouth and Melcombe Regis.—Urban District Council.—Medical Officer of Health. Salary £300 per annum. Applications to Richd. Nichols, Howard, Town Clerk, Municipal Offices, Weymouth.

Fisherton Asylum.—Assistant Medical Officer. Salary £150 per annum to commence, with board, lodging, and washing. Applications to Dr. Finch, Salisbury.

Kent County Asylum, Barming Heath, Maidstone.—Fourth Assistant Medical Officer and Pathologist. Salary £175 per annum, with furnished quarters, attendance, coal, gas, garden produce, milk, and washing. Applications immediately, to F. Pritchard Davies, M.D., Superintendent.

Kings Norton and Northfield Urban District Council.—Medical Officer of Health. Salary £500 per annum. Applications to Edwin Docker, Clerk of the Council, 10, Newhall Street, Birmingham.

Liverpool Stanley Hospital.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Chairman of the Medical Board.

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £110 per annum, with board and lodging. Applications to the Chairman of the Selection Committee at the Hospital.

Royal Cornwall Infirmary.—House Surgeon (unmarried). Salary £100, board, and apartments. Applications to the Secretary, 4, Parkverras Terrace, Truro.

West Riding Asylum, Wakefield.—Pathologist and Assistant Medical Officer. Salary £140, with furnished apartments, board, washing, and attendance. Applications to the Medical Director.

Births.

CHARLES.—On April 22nd, the wife of J. R. Charles, M.D., M.B.C.P., Pelsall, Staffordshire, of a daughter.

TURNER.—On May 2nd, at Purley, Surrey, the wife of S. Duke Turner, M.B., D.P.H., of a daughter.

Marriage.

MURRAY-McNAIR.—At the Cathedral, Bombay, on April 11th Captain John George Patrick Murray, M.B., C.M. Edin., Indian Medical Service, eldest son of Deputy Inspector General George Bell Murray, R.N., to Grace Edith, only daughter of J. W. A. McNair, Esq., Lahore, Punjab.

Deaths.

ADAMS.—On April 30th, at Springwell, The Terrace, Barnes A. J. Bowman Adams, M.B.C.S., L.R.C.P., eldest son of Dr. James Adams, of pneumonia, aged 38 years.

BERRY.—On May 2nd, at 66, Pembroke Villas, London, W., Henry Thomas Berry, M.B.C.S., in his 63rd year.

STEPHENS.—April 30th, at Lynton, N. Devon, Daniel Robert Porritt Stephens, M.B. Camb., F.R.C.S. Eng., eldest son of the late Daniel Woolcott Stephens, of Hinderswell, Yorkshire.

A CASE OF PYÆMIA FOLLOWING OTITIS MEDIA.

By WM. MURRELL, M.D., F.R.C.P.,

Physician to the Westminster Hospital, &c.

THE diagnosis and treatment of otitis media, especially when followed by pyæmia, is a subject which of late has attracted a good deal of attention, and it is only by a careful and systematic record of clinical cases that we can hope to arrive at a definite conclusion. Dr. Philip Hammond, of Boston, Mass., in a recent paper on "Indications for the Mastoid Operation" (*American Medicine*, April 12th, 1902), points out that the absence of temperature is no guide whatever. There may be considerable elevation of temperature during the more acute stage of the inflammation, but this usually subsides as soon as a free discharge from the drum cavity occurs. Dr. Hammond also emphasises the fact that absence of tenderness of the mastoid on pressure signifies nothing, for the cortex is extremely thick in many cases, and an acute inflammation must have existed for some time to become apparent to the touch through so much bone. Probably the most difficult and unsatisfactory cases are those in which there has been a chronic or latent discharge from the ear, followed by apparent recovery. A case of this kind may go on some years, giving rise to very little pain or inconvenience beyond a little slightly offensive discharge; suddenly, however, the whole condition becomes septic, and the patient is in a position of extreme danger.

The following case, which ran a short course and terminated fatally, is instructive in many ways:—

F. R., a boy, æt. 14, was admitted on March 27th, 1902, suffering from pyæmia. From the history it appeared that whilst at school he had contracted measles, followed by broncho-pneumonia. In the course of the illness a foetid purulent sanguineous discharge was noticed from the left ear. Some days before admission to the hospital a fluctuating swelling was discovered, apparently involving the right sterno-clavicular articulation, with another over the right elbow. The temperature for nine days whilst at the school was of a hectic type, ranging from 103.2° to 104.6° at night, and falling to 99.2° in the morning. Sweating was profuse, but there were no rigors.

The general condition of the patient on admission was good. The temperature at 8 p.m. was 102°. A few moist sounds were heard over both lungs, but there was no consolidation either at apex or base. The heart sounds were normal; the pulse was 128, of fair volume, and there was no albumin in the urine. The tongue was furred, but the breath was

not offensive. The swelling over the elbow was about the size of a hen's egg, fluctuated freely, and undoubtedly involved the joint. The swelling in front of the sternum was smaller, but evidently also contained pus. There was some discharge from the ear, but it was not very offensive, and on percussion over the bone no tenderness could be detected. At 9 p.m. on the day of admission the abscesses were opened by Mr. Walter Spencer, but it was decided to leave the ear untouched. Streptococci were found in the pus from the abscesses. For some days the wounds discharged freely, but there was no fall in temperature, which continued to range from 100° to 104.8°. The patient's general condition was very unsatisfactory, and brandy and champagne had to be given, with occasional hypodermic injections of one-sixtieth grain of strychnine. On March 30th, an examination of the blood showed 24,000 leucocytes per cmm., consisting of finely granular cells, 89 per cent., coarsely granular, 5 per cent., hyaline, 2 per cent., and transitional, 4 per cent. On April 1st the patient's condition was so critical that it was determined to operate on the ear. Under gas and ether, administered by Mr. Nimmo Watson, Mr. Spencer opened up the lateral sinus and evacuated a small quantity of very foetid pus. The opportunity was taken of examining and further laying open the abscesses connected with the elbow and the sterno-clavicular articulation. The recovery was fair, and on the following day the highest temperature was 101.4°, the pulse 142, and the tongue clean and moist. There were, however, indications of collections of pus in the left ankle, in the right hip behind the great trochanter, and over the sacrum, the last apparently having commenced as a bed-sore. On April 3rd all these abscesses were laid open freely. The patient was kept in a boracic acid bath, but there was no material fall in temperature, and the pulse ranged from 124 to 136, becoming more and more feeble. The patient died at 9.30 p.m. on the 7th.

Autopsy (by Dr. R. G. Hebb) ten hours after death. —Body much emaciated, flaccid. Surgical wound behind the left ear with deep excavation where part of the petrous portion of the temporal bone has been removed. Right elbow-joint freely open. Pus in right sterno-clavicular articulation and in adjacent parts. Pus in both hip-joints and right ankle joint, and purulent lymph in left shoulder-joint. Brain 3½ lbs., sub-arachnoid œdema, nervous substance rather soft, otherwise normal. Pia normal except at outer surface of dura just outside jugular end of lateral sinus, where there is purulent lymph; the dura normal. There is a clot in the left lateral sinus, adherent and yellow, near bone, but beyond this soft and black. No clot in jugular vein. All the other organs normal.

Mr. Philip de Santi, who examined the temporal bone, reported that there was septic thrombosis of the lateral sinus due to middle ear suppuration.

This case illustrates forcibly the necessity for scrupulous care in the treatment of acute suppurative inflammation of the middle ear, and the importance of prompt surgical interference. There was no difficulty in diagnosis, and the point of infection was recognised from the first. Such, however, is not always the case, and in a pyæmia following otitis media which I published with Mr. de Santi (*British Medical Journal*, December 21st, 1901) the origin of the mischief was disclosed only at the necropsy, when the left middle ear was found to contain pus in small but definite quantities, the tympanic membrane being widely perforated. In the present case there were no head symptoms, and it was rightly concluded that there was no cerebral or cerebellar abscess, and that the meninges were not involved. It was a typical case of arthritic pyæmia, but why the brunt of the attack should have fallen on the joints, leaving the viscera free, it is difficult to say. The patient was sound of heart and lung and this probably affords an explanation of the good fight he made in spite of the extensive suppuration. In this connection the large proportion of leucocytes will be noted. Baldy, of Philadelphia (*American Medicine*, March 15th, 1902), has thrown doubt on the value of blood counts in surgical cases, but useful information is often afforded by them especially in the matter of prognosis. Leucocytosis occurs only when the struggle between the patient and his disease is intense. A blood count of 24,000 is high, but Cabot records a case of septicæmia with arthritis in which the white cells numbered 43,000, and a case of sloughing breast in which there were 48,000 per cmm.

Whether anti-streptococcus serum should have been employed in this case is a moot point. I have seen so much good from it in cellulitis, general suppurative peritonitis, in diseases of the middle ear, thrombosis of the lateral sinus, and in other form of septicæmia, purulent surgical affections, that I am not likely to discard it lightly. I remember especially a case under Mr. Spencer of acute pharyngitis due to *streptococcus pyogenes* followed by deep glandular inflammation and pericarditis which was cured by streptococcus serum. But in the present case the fact that the patient had been infected for nine days before admission seemed to me to be an argument against its employment. It is quite possible that instead of improving his condition it might have made him worse. I have heard of a somewhat similar case in a child, in which an injection of 20 cc.—undoubtedly too large a dose—proved rapidly fatal.

Vienna Clinical Lecture.

BLOOD PRESSURE IN CHRONIC NEPHRITIS.

By Dr. ERNST VON CZYHLARZ,

Assistant to Professor Nothnagel.

THE following observation may be of interest to the profession from the fact that in the whole range of medical literature no similar researches have yet been placed on record which can lay claim to any degree of accuracy. The following results have been obtained in Professor Nothnagel's service with Gärtner's "tonometer" which is now acknowledged to be as valuable an instrument in clinical observations as is the stethoscope, the urinometer, or the thermometer, as has been shown on many previous occasions. I shall commence at once by giving the facts as observed.

CASE I.—S. M., æt. 35, potter, chronic interstitial nephritis or lead-poisoning kidney. When admitted

on February 2nd last year, he passed 2,600 c.c. (92½ ozs.) of urine, sp. gr. 1012, nucleolar albumin nil, but albumin was present to the extent of 0·5 per cent. Sugar 0; acetone 0. In the sediment a few granular casts. Tonometer 210 millimeters. The cardiac impulse was in the fifth intercostal space one finger's breadth outside the nipple line. He complained of headache and dyspnoea, but there was no oedema. Pulse 90, radial artery moderately dilated, thickened and serpentine in outline.

February 3rd.—2,400 c.c. of urine passed; sp. gr. 1020; albumin 0·5 per cent.; sediment as above; tonometer 210 mm.; while the objective and subjective symptoms are unchanged.

4th.—Urine 2,800 c.c.; sp. gr. 1010; albumin 0·5 per cent.; sediment as before; tonometer 200 mm.

5th.—Urine 2,400; sp. gr. 1009; albumin 0·5 per cent.; sediment same; tonometer 200 mm.; general condition better; objective condition unchanged.

6th.—Urine 2,500; sp. gr. 1010; albumin 0·5; sediment as above; tonometer 200 mm.

7th.—Urine 2,400; sp. gr. 1011; albumin 0·5 per cent.; tonometer 200 mm., or 7·874 ins. of hg.

8th.—Urine 2,200 c.c.; sp. gr. 1013; albumin less than 0·5; sediment as before; tonometer 205; patient complained of headache.

9th.—Tonometer 200 c.c.; general conditions good.

10th.—Tonometer 200 c.c.; general conditions good.

11th.—Tonometer 180 c.c.; general conditions good; objective symptoms offered nothing for remark.

	Mm. Hg.		Mm. Hg.
12th.—Tonometer	180	21st.—Tonometer	165
13th.— Ditto	175	22nd.— Ditto	155
14th.— Ditto	180	23rd.— Ditto	150
15th.— Ditto	175	24th.— Ditto	160
16th.— Ditto	170	25th.— Ditto	160
18th.— Ditto	170	26th.— Ditto	150
19th.— Ditto	160	27th.— Ditto	160
20th.— Ditto	175	28th.— Ditto	155

At this time patient was discharged from hospital as well. During his stay there he was kept in bed on milk diet. The headache lasted but a short time after admission as a constant symptom, then became periodical, and finally only occasional and transitory. The dyspnoea and other uræmic symptoms disappeared with the headache. The quantity of albumin remained almost constant throughout at 0·5 per cent. The urine varied in amount between 2,000 c.c. and 2,600; on the day preceding his discharge it was 2,300 c.c.

CASE II.—T. M., æt. 58, farmer, with chronic interstitial nephritis and arterio-sclerosis. He was admitted on August 5th with severe headache, consciousness unimpaired, but there was vertigo and persistent vomiting. The cardiac impact was in fifth intercostal space in the anterior axillary line, and could be seen beating on the thoracic wall. The radial artery was tortuous and dilated, and its walls were much thickened. Pulse 82, arhythmic, regular, but quick. Tonometer, 225 mm. No oedema. Urine, 3,000 c.c. Sp. gr., 1010. Nucleolar albumin, 0. Ordinary albumin, 0·5 per cent. Sediment contained a few granular casts.

	Mm.	
Aug. 6th.—Tonometer	200	Urine unchanged and other conditions same.
7th.— Ditto	200	Ditto.
8th.— Ditto	190	General conditions better, especially the headache. No vomiting.
9th.— Ditto	180	Ditto.
10th.— Ditto	180	Patient feels better. Objective symptoms unchanged. Albumin 0·5 per cent. Sediment, with granular casts.

11th.—	Ditto	180	During this period urine 3,000 c.c.; sp. gr., 1011; albumin, 0.5 per cent. A few granular casts. Patient felt perfectly well and was discharged.
12th.—	Ditto	175	
13th.—	Ditto	175	
14th.—	Ditto	180	
15th.—	Ditto	170	
16th.—	Ditto	165	
17th.—	Ditto	160	

This is a fair picture of ten other cases followed by similar results which need not be recapitulated here. They all go to prove that the blood pressure is undoubtedly lowered in chronic nephritis by confinement to bed with proper treatment and suitable diet. This lowering of the blood pressure is not accompanied by any other symptom indicative thereof, since no cardiac enfeeblement is evident during the course of the disease unless, indeed, it be inferred from the subjective symptoms of the patient himself, who states that he feels perfectly well when the fall takes place. The severe headache, vertigo, and persistent vomiting subside as soon as the blood pressure begins to fall, so that this may be regarded as the cause of these grave symptoms and should, therefore, receive early attention.

ANÆMIA IN DISEASES OF THE SKIN.

By DAVID WALSH, M.D. EDIN.,

Hon. Physician, Western Skin Hospital, London, W.

THERE can be little doubt that the condition of anæmia, using that term in a wide and general sense, has a considerable influence not only in the causation but also in the modification of many diseases of the skin. Indeed, the determination of blood to the surface of the body explains to a great extent the action of many applications and plans of treatment in cutaneous maladies. Looked at in this way, it seems likely that in not a few cases the baths, lotions, ointments, and other remedies used by the dermatologist effect a cure mainly by increasing the flow of blood to the skin. It may be said broadly that the great lesson to be learned in the treatment of skin troubles is when to soothe and when to stimulate, or, to put the matter in other words, when it is desirable to induce either local anæmia or local hyperæmia.

To take a case in point, say, an ordinary pale pink, old-standing patch of chronic psoriasis. Although the process is undoubtedly of a chronic inflammatory nature it seems more than likely that in the later stages local anæmia results from the thickening of the skin and the obliteration of the capillaries. Rub this patch with some highly irritant application, such as chrysarobin, and the psoriasis rash will sometimes rapidly melt away. The action of this irritant drug is to set up an intense vascular flush of the skin to which it is applied, whereby the thickening of the skin is absorbed and the offending microbes that probably lie at the root of the malady are destroyed. Anyway, judging by results alone, the good effect of strong stimulation upon psoriasis may be taken as an instance of cure dependent upon the correction of local anæmia.

The pallor of many of the patients who attend a skin hospital is a noticeable feature of that class of practice. One of the first conditions that suggests itself is that of the so-called physiological acne of the young adult. The pale face, the small pulse, the coated tongue, and the constipation, as everyone knows, are constantly associated with the crop of "black-heads," papules and pustules scattered over the face. In such cases ordinary treatment comprises among its essentials the internal administration of some iron compound and the external application of a stimulant, as sulphur. There are various constitutional states characterised by pallor and associated

with multiple rashes of the skin; among them may be mentioned chiefly rickets, tuberculosis, syphilis, and chronic disease of the kidney. In all these cases the skin manifestation may be due either to the local anæmia of the surface or to the local excretion of some poisonous products, or to both causes acting together. In any case successful treatment will depend upon the correction of the anæmia of the skin by appropriate external and internal remedies.

It is not intended to enter fully into this most interesting and suggestive subject in the present article, which is intended to be more in the nature of a preliminary communication than of a formal discussion. At the same time a word may be said of the pruritus that is often one of the most distressing complaints brought under the notice of the dermatologist. The most serious and obstinate forms of this malady are often met with in persons who are past middle age, or have attained old age. In them the decline of life is sometimes rendered a burden by the incessant irritation and itching of the skin, which leads to scratching that is surreptitious by day and involuntary by night. That there is some relation between this disturbance of the sensory nerve-ends and the local anæmia of the skin seems more than probable. In a fair number of these trying cases it is possible to find a cause in some external irritant, such as that of body parasites, from which no class of society, high or low, is exempt. In a larger number, however, one cannot discover any such obvious starting-point for the generalised itching. In such cases, quinine or salicylate of soda are sometimes useful when given internally, and mild iron preparations. Hot baths often afford relief, and creolin may be added, in the strength of about one teaspoonful to the gallon of water. In elderly people the writer has found the hot creolin bath answer best in combination with tablespoonful doses of Hommel's hæmatogen twice daily. The latter is a mild preparation of organic iron, and is of considerable value in the treatment of anæmia as a complication of skin complaints. From its non-constipating and slightly stimulant qualities it is specially adapted for children and for old persons. Menthol soap, as advised by Norman Walker, may relieve the itching. He advises that the patient be lathered all over before going to bed, and should then sleep in a flannel night-dress. It is only as a last resort and in desperate cases of pruritus that narcotics should be used. To resort to drugs of that kind is to confess that one has been baffled both in discovering the origin of and in treating the mischief.

For robust persons the sulphate of iron in combination with sulphate of magnesia forms an excellent alterative mixture.

One of the most powerful modern remedies placed in the hands of the dermatologist is the superheated air system introduced by Mr. Tallerman. Copious sweating is produced, and so powerful is the influence upon the skin that the present writer has been able to cure chronic eczematous conditions by that means alone. In most chronic skin troubles it is also necessary to act on the other excretory organs, especially the bowel and the kidneys, by the use of aperient waters, and to improve the quality of the blood by the administration of iron in the form most suitable to the needs of the individual case. The writer has a case of chronic psoriasis covering roughly about one-half of the body surface. It had resisted all kinds of treatment, including violent stimulation with chrysarobin ointment. Under the Tallerman treatment the improvement has been immediate and rapid, and has given results that were attainable by none of the ordinary plans of treatment. At the same time it is more than likely

that to prevent recurrence careful external treatment with antiseptic applications will also be required.

Recent researches have shown that secondary *anæmia* is a symptomatic condition of wide significance, in which the red and white corpuscles and other constituents of the blood may be variously altered to an almost unlimited extent. The most familiar instances of skin eruptions associated with more or less profound pallor are those met with in lead poisoning, Bright's disease, and in the subjects of tuberculous or cancerous disease. The way in which some skin affections run riot in these cases must be familiar to all who have had much experience in that class of affections. It is perhaps best seen in the case of the mixed and other hypertrophic skin lesions frequently met with in patients having a tuberculous family history.

Toxic *anæmia* may be due to absorption of toxic products from a skin affection. This often happens in the case of children who have extensive suppurating eczematous or other inflammatory cutaneous troubles. The pallor of such patients suggests that the skin is deprived of its most efficient weapon in regaining a healthy state, inasmuch as its blood supply is defective both in quantity and in quality. In young children presenting this combination of severe eczematous trouble and pallor of skin the author has found hæmatogen most valuable in teaspoonful doses twice daily in milk. At the same time it is of course necessary to attack the skin from the outside with various soothing and antiseptic applications. Often the most useful plan in the case of young children is to apply the antiseptic in the medium of a warm bath, followed by the application of drying antiseptic dusting powders to the affected skin. It is well known that cases of eczema in *anæmic* children are frequently most rebellious to treatment, and a cure may be delayed for months or even for years, with lasting injury to the constitution. The best chance for recovery will be afforded in such cases by a combined plan of external and internal treatment with appropriately chosen remedies.

NOTES ON A CASE OF LEAD POISONING. (a)

By R. B. McVITTIE, M.D.

A RETIRED Indian officer, *æt.* about 58, who had always enjoyed fairly good health in India with only occasional slight attacks of fever, settled with his family in a fine country house most healthfully situated. In about three months time he began to complain of some general seediness, loss of appetite and muscular weakness, which he attributed to having over-exerted himself, being always a man of unusually active habits. A month later he suffered from occasional very severe attacks of abdominal pain, with increasing nausea and loss of appetite.

After a residence of six months he was seized with the first really violent paroxysm of vomiting, abdominal pain and constipation, the remaining members of the family being all in good health. From this attack he made a partial recovery, and was able to take a little food, and get about again. He now began to observe what he described as a "fumblyness" about his hands, especially the right, and became unable to button his clothes or write a letter. He was supposed to have gout by some medical men who saw him and was ordered to Buxton, where he underwent treatment with baths and waters from which he derived very little, if any, benefit, although perhaps the change effected some improvement in his appetite.

(a) A Paper read before the Section of State Medicine of the Royal Academy of Medicine in Ireland.

He had returned to his residence when I saw him, and was taking thialion. He had right wrist-drop, but having lost all his natural teeth during the Burmese campaign, there was no line on the gums. He still had occasional attacks of nausea and a tendency to constipation; he, however, could sometimes take his meals pretty well, but always observed that the soup increased the nausea, and was unnaturally depressed and irritable.

The water supply was examined and I found it to be supplied from two wells situated in a field above and behind the house at a distance of about 100 yards. The pipes from the wells appeared to be iron, but in the house the tap from which most of the water was drawn was attached by a few feet of lead piping to the main coming from the wells, and water taken in the morning from this tap contained, according to Dr. Lapper's analysis, 1·67 grains of lead, while that taken direct from the well contained no lead.

Since this discovery he has used water taken directly from the wells with complete restoration to his general health, although the right hand has not yet fully regained its power.

The disastrous consequences of resting satisfied with an incorrect diagnosis are forcibly brought home to us here, for while this poor man was supposed to have gout he was continuing to poison himself every day, and was going rapidly down the hill.

It is remarkable that one member only of a large household should suffer so severely while the others escaped any manifestations of injurious effects. This was probably explained by the facts that he was the oldest member of the household by a good deal, and that having been exposed for many years to the injurious influences of the Indian and Burmese climates, his eliminatory organs were probably not in as active a condition as those of the other members of the household; and further, that he probably consumed more water per diem than any of the others, as it was his custom after active exertion about the place to come in and take large draughts of water with whiskey in them.

The nausea after the soup is interesting, and may perhaps be explainable from the fact that soups are usually made by a prolonged process of simmering or slow boiling, and that in this way by evaporation a certain amount of concentration would result by which he would take a larger quantity of lead in a given quantity of fluid.

CLINICAL NOTE ON THE VALUE OF HYDRASTIS CANADENSIS IN RENAL HÆMORRHAGE.

By WM. BRAMWELL, M.A., M.D., B.Ch.,
Liverpool.

HYDRASTIS canadensis is now one of the official remedies in use at the Rotunda Hospital, Dublin, to check hæmorrhage from the uterus. It does not however seem to have been much resorted to in cases of hæmorrhage from the kidneys. The following case will I think, be a good instance of its value in hæmorrhage of this nature which sometimes baffles all our efforts at successful treatment.

J. G., a man, *æt.* 65, came to me some time ago complaining of what he thought was blood in his urine. He said that he had had a stroke a year previously, from which he had so far recovered as to be able to attend to his business, though not with the same regularity as formerly. I found his heart considerably hypertrophied, and there was a loud mitral regurgitant murmur. The urine was of high specific gravity, of deep blood colour, answering to

the usual tests for blood, and depositing large quantities of coagula on the floor of the vessel.

I concluded that my patient was suffering from the hæmorrhage of congested kidney, and tried many remedies directed to this cause but without effect, until I resolved to try hydrastis. This I gave in ten minim doses of the fluid extract every two hours, at the same time taking care to keep the bowels free. By the end of the first day of this treatment there was marked improvement, and in three days the hæmorrhage had entirely ceased, nor has it since returned.

The above case seems to point to this drug as worthy of trial in those cases of obstinate renal hæmorrhage which one occasionally meets with.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MAY 9TH, 1902.

HOWARD MARSH, F.R.C.S., President, in the Chair.

CONGENITAL DIFFUSE LYMPHANGIOMA TERMINATING IN LYMPHOSARCOMA AFTER LYMPHANGITIS.

MR. W. G. SPENCER read a paper under this title. The case was as follows:—A girl, *æt.* 4, was born with the right leg longer than the left. It caused no uneasiness until, without any assignable exciting cause, it became swollen by inflammation immediately before coming under observation. For the following three months until death there was marked and continuous hectic fever, an evening temperature of 103° F., with a fall to a subnormal morning temperature of 97° F. or even 96° F. The pulse throughout was about 130 to 140, on many days rising to 170 or even 180 per minute. The respiration was constant at 35 to 40 per minute (chart shown). First the leg, then the thigh, and finally the hip, loin and groin became swollen, with, in the later stage, some decrease of size in the leg and lower thigh. There was no change in the skin, but small incisions allowed serous fluid to escape, with fibrinous casts of the dilated lymphatic spaces, white globular masses the size of pear and beans. Streptococci, and at other times staphylococci, were found in the discharge, but there was no true suppuration or pus found until the day of death, when a small collection was present in the region of Scarpa's triangle. No chylous fluid ever escaped, nor did lymph vesicles form on the skin, nor did the skin become rugose. *Post-mortem*—The swellings of the thigh and hip region were found to be due to dilated lymphatic spaces with intercytic masses of lymphosarcoma, as shown in microscopic sections. Other cases including macroglossia, in which congenital lymphangioma has terminated in lymphosarcoma, were mentioned. The fever in this case was continuous, not remittent.

Dr. H. D. ROLLESTON took exception to the term "lymphosarcoma," as applied to this case, and thought that the condition would be more correctly expressed as "lymphatic-gland sarcoma."

Mr. GEORGE TURNER communicated a case of

PRIMARY SARCOMA OF THE SYNOVIAL MEMBRANE OF THE ANKLE-JOINT.

The patient was a man, *æt.* 28, who two months before admission into St. George's Hospital knocked his foot against a brass screw. Three weeks after this he noticed a swelling in front of the right ankle. This had slowly increased in size and measured about 1½ by 1½ inches. There was no obvious connection with the tendons. When removed it was found to be growing from the synovial membrane of the ankle-joint. Dr. Rolleston reported the tumour to be a fibrifying and chondrifying mixed-cell sarcoma. Attention was drawn to the rarity of primary sarcoma of synovial membranes of joint. Myelomata of tendon sheaths are much more commonly met with, and are innocent clinically, differing thus from a case recorded by the President of primary sarcoma of the synovial membrane of the knee-joint.

The patient was shown to the Society at a clinical evening early in the year.

Mr. C. B. LOCKWOOD read a paper on a case of

SARCOMA OF THE SYNOVIAL MEMBRANE OF THE KNEE.

The patient was a young married woman who had disease of the right knee of three years' duration. The joint was slightly flexed, but possessed almost its full range of movements. The capsule was slightly distended by a swelling of the synovial membrane which made the circumference of the joint three-quarters of an inch greater than its fellow. The surface of the swelling was rather warm, and it was tender on pressure. A consultation was held, and the opinions were almost unanimously in favour of the disease being tuberculous. As no treatment had been tried it was thought well to rest the joint and apply a splint. Nothing was seen of the patient for about a year, when she returned with what appeared to be well-marked tuberculous disease of the knee. A resection was performed, and the absence of carious material or of pus excited some suspicion. The material was independently examined by two pathologists and pronounced to be "spindle-celled sarcoma" and "oval-celled sarcoma." When first seen two points might have excited suspicion that the disease was not tuberculous, (1) the absence of muscular wasting, (2) the free and painless mobility of the joint after having been the seat of supposed tuberculous disease for three years.

In the discussion on these two papers,

The PRESIDENT referred to the case alluded to by Mr. Turner, which he had reported in the thirty-second volume of the Society's "Transactions." The patient, a man, *æt.* 21, was admitted into St. Bartholomew's Hospital on account of a swelling in the knee, which had existed for fifteen months. When the knee-joint was opened the growth was found to be surrounded by synovial membrane. It was removed, and recurrence of the growth took place four times, the first time after three years and the last time six years from the time he came under observation. On the last occasion the leg was amputated. It was remarkable to note how the growth successively affected different portions of the synovial membrane. Microscopical examination showed that it was a spindle-celled sarcoma. The patient was at the present time alive and free from any return of the disease. By a curious coincidence he was in the hospital a few days ago with consolidation in one lung. Knowing his history, it was feared that the lung was the seat of growth, but it had cleared up. A short time ago the President had seen a young woman, *æt.* 22, with a condition very like that found in Mr. Turner's case, except that the tumour was in the knee. When the joint was opened, the growth was almost pedunculated. It proved to be a sarcoma. Mr. Lockwood had dwelt on a very important point, namely, the obscurity of the diagnosis in these cases. Mr. Lockwood had remarked that the temperature had led him to suppose that the disease was tuberculous, but this was not really a trustworthy guide in differential diagnosis, because malignant growths in joints were not infrequently found associated with high temperature.

Mr. W. G. SPENCER called attention to an important point of difference between Mr. Lockwood's case and the others, in that the growth in Mr. Turner's case and in the President's was localised, whilst in Mr. Lockwood's it was diffused. This feature of the latter case rendered the diagnosis additionally difficult. The President's case appeared to resemble a class of tumour recently referred to in a sister society as "endothelioma." With regard to diffuse growths in the synovial membrane, as distinct from tuberculous, he had seen two cases which were put down as "rheumatic" without any sufficient evidence for this view. There was a case also under the care of his colleague, Mr. Stonham, of a girl with a tuberculous history. When the joint was opened there was no evidence of tubercle, and it may have been a case either of a fibrous condition or of sarcoma. Mr. Hardie, of Manchester, had described in 1894 a sarcoma occurring in the synovial membrane of the knee-joint. These rare forms of sarcoma appeared to run a different course

to that observed in the case of sarcoma attacking bones.

Mr. TURNER, in reply, said that the discussion had shown, as Mr. Spencer pointed out, that these sarcomata were of two kinds, the circumscribed and the diffuse. In his case tuberculosis was not even thought of before operation; the diagnosis lay between some kind of new growth and a bursal cyst.

Mr. LOCKWOOD also briefly replied.

A CASE ILLUSTRATING SOME OF THE CLINICAL FEATURES OF "HORIZONTAL" DILATATION OF THE LEFT AURICLE.

A paper on this subject was contributed by Dr. WM. EWART and Dr. ISAMBARD OWEN. The authors premised that a complete account of the clinical features of this affection was not yet possible, but they had endeavoured to bring out some of the broad lines which might facilitate its identification by comparing the clinical record of the original case published by Drs. Owen and Fenton in the last volume of the Society's "Transactions" and that of the present case which was exhibited before the Society in January of this year with a provisional diagnosis of the condition in question. The patient, an omnibus driver, æt. 32, subject to winter coughs, had had pneumonia in 1896, but denied any rheumatic, syphilitic or other affection. He dated his illness from a "chest cold" one month before his admission on November 20th, 1901. In spite of palpitation and dyspnoea during the last fourteen days he had remained at work until unable to get up on November 19th. *Condition on Admission.*—Face slightly puffy, with dusky lips and complexion; no ascites and hardly any anasarca; only slight enlargement and occasional pulsation of liver. External jugular veins filled, but not greatly distended nor visibly pulsating. Pulse irregular and quick, with many small beats; respiration quick and without much distress. Coarse rales; slight cough, no expectoration. Extensive cardiac impulse in the left precordium. A visible and palpable impulse was also perceived below the level of the right nipple and internal to the latter—chiefly in the fourth intercostal space. This was the seat of the habitual pain described by the patient, and, together with the epigastrium, was the only tender part, the left precordium not being tender or painful. The apex beat was under the sixth rib, about 1½ inch beyond the left mid-clavicular line. Two murmurs, a slight and uncertain presystolic, and a distinct steady systolic, were audible at the apex; and they were also heard with almost undiminished clearness in the right infra-mammary region, where there was occasional thrill. Percussion yielded a considerably widened dullness anteriorly, and a characteristic increase in the auricular dullness in the back. Gradual improvement occurred under rest, tonics and stomachics, and he was successfully treated for fistula. On December 30th, after a period of tympanitic abdominal distension, a free hæmoptysis occurred, and on the 31st he was bled to 16 ozs. with great relief. From that time he slowly gained strength, and was allowed up on January 7th. He was now able to walk slowly on the level without dyspnoea, and the pulsation in the right infra-mammary region was not perceptible except after hurried walking or stooping. The pulse has also improved, but is still weak and irregular. *Clinical Remarks.*—The etiology of this apparently rare affection remained obscure. The chief clinical features were insidiousness of onset, gradual progression, long-continued latency and remarkable toleration for the auricular dilatation which was permitted to grow without necessarily setting up severe pain, dyspnoea or other urgent symptoms until loss of compensation supervened. By means of skiagraphy the diagnosis might perhaps in the future be made at a comparatively early stage, but not without the help of dorsal percussion, and, in particular, of percussion of the left auricle. *The leading objective signs* noted were: 1, Systolic pulsation with or without thrill in the right fourth intercostal space; 2, synchronicity of this pulsation with the apex beat; 3, equality in the loudness of the existing murmurs at the pulsating area and at the apex; (4) great increase in the transverse diameter of the præcordial dullness which might extend towards the right beyond the mamillary line; (5) increase of the

post-cordial dullness, with a characteristic enlargement (chiefly in the transverse diameter) of the post-auricular dullness with a loss of its symmetry; 6, the liver might be at times the seat of an inconstant pulsation; 7, the absence in this case, in spite of the cyanosis and dyspnoea, of any advanced general or serous dropsies was remarkable; 8, the dyspnoea seemed to present an important clinical peculiarity in its association with cyanosis and with quick breathing without any great respiratory distress. More striking still was the readiness of the present patient to lie almost flat, in marked contrast with the common type of orthopnoea seen in advanced cardiac cases; 9, lastly, an important confirmatory sign was the impairment of the respiratory movements and sounds on the right side of the chest. *The subjective symptoms* were above all the pain and tenderness localised to the right of the sternum in contrast with those special to ordinary cases of mitral stenosis in which the pain was referred to the ventricular or left parasternal region. To the dyspnoea reference has already been made. As regards prognosis and treatment the inference was that the condition when fully developed was not likely to be cured. The observations in hand tended, however, to show that considerable alleviation might be effected by rest and by venesection, rather than by medicinal treatment.

Dr. ISAMBARD OWEN also contributed a paper on "Horizontal Dilatation of the Left Auricle," with special reference to other cases and specimens besides the one he had shown in May, 1901. Inquiries at all the principal museums and medical schools in the United Kingdom had shown that only two other specimens were known to be in existence, namely, one in St. Bartholomew's Hospital and one in University College. These were briefly described, after which Dr. Owen compared and contrasted the most important clinical and pathological features of the three cases.

In the discussion on these two papers,

Dr. A. F. VOELCKER inquired whether in Dr. Ewart's case there was any murmur in the tricuspid area. He asked what were the grounds for supposing that the pulsation observed on the right side was due to dilatation of the left auricle. It seemed to him open to consider this pulsation as due to dilatation of the right auricle.

Dr. HERRINGHAM expressed himself in a similar sense. It appeared to him that all the signs described by Dr. Ewart could be explained by the assumption of dilatation of the right auricle.

Dr. EWART, in reply, briefly gave the reasons which led him to the conclusion that the principal dilatation affected the left, and not the right, auricle.

Dr. EWART also read a short note on

PALPABLE SYSTOLIC INTERCOSTAL PULSATION IN A CASE OF MITRAL STENOSIS, WITH DILATATION AND THROMBOSIS OF THE LEFT AURICLE.

The purpose of this communication was to elicit further information concerning the significance of systolic pulsation felt over the region of the right auricle, the frequency of its occurrence, the various modes of causation, and the value which it might possess as a diagnostic physical sign. In this instance the systolic pulsation felt at the fourth and fifth intercostal spaces had been regarded during life as due to the direct pulsation of an enlarged left auricle. But it was found after death that the seat of the pulsation corresponded to the surface of the right auricle. The left auricle was, however, markedly dilated above a button-hole stenosis of the mitral valve, and was completely filled with a spongy thrombus which had partly broken down into a grumous fluid. The history of the case was then briefly related. The author considered that visible and palpable pulsation of the right auricle did not belong to the normal cardiac function; if capable of being felt the beat should presumably be diastolic or presystolic in time. In the ordinary cases of dilatation of the right side of the heart he had not hitherto noted any pulsation to the right of the sternum. When the heart was displaced into the right chest the abnormal pulsation is systolic, and to be regarded as a direct ventricular pulsation conveyed from the ventricular walls. If palpable systolic

pulsation to the right of the sternum (not due to intrapericardial aneurysm) was as uncommon as he believed it to be, a study of its conditions of occurrence was of importance, and any definite observations by others on this point would be of value. Pulsation within the auricular area of the præcordium had now been shown to be sometimes due to the left auricle when immensely enlarged. The present case showed that on the other hand a systolic pulsation might be transmitted through the right auricle when the left auricle was distended in such a way as to be incapable of performing its systolic contraction. To these modes of causation others might probably be added as the result of future inquiry.

The meeting then adjourned.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

MEETING HELD AT THE ROYAL COLLEGE OF SURGEONS ON FRIDAY, MAY 2ND, 1902.

Professor E. J. McWENNEY, M.D., President, in the Chair.

THE PRESIDENT called on the Hon. Secretary of the Section (Professor White) to read the report of the Reference Committee on the specimens of diseased vertebrae exhibited at a previous meeting by Dr. Doyle. The report stated that the inflammation which had been present in the vertebrae had caused the absorption of a large portion of the transverse ligament of the atlas, but that neither tuberculous disease nor suppurative inflammation had occurred.

Dr. CRAIG and Professor WHITE then read their paper, on

CASE OF CONTINUED FEVER DUE TO THE BACILLUS ENTERITIDIS OF GÄRTNER.

Dr. Craig said the patient who is the subject of the communication was an unmarried man, æt. 22, of temperate and regular habits. About September 18th, 1901, he complained of not feeling well, was out of sorts, and to recuperate he went home to Wexford for ten days. On the 24th, he had shiverings, felt worse, and during the next few days vomited several times; had slight diarrhoea, but felt no pain. He returned to Dublin on the 28th of the month, and on the 30th he visited the Meath Hospital, where he came under his (Dr. Craig's) notice. His temperature was 103°; pulse 100; respirations 24; his tongue was furred with a creamy matter, though clean at the tip and along the margins. When protruded it was seen to be ataxic; the patient was covered on the front and back of the trunk with rose spots, and was suffering from diarrhoea, the stools being thin and yellowish. Typhoid fever was diagnosed, and the man was admitted to hospital. The following day the temperature was 104°, his cerebration was slow, he was disinclined to talk, lay on his back, had an eruption of herpes labialis, and in the evening his temperature reached 104°8'. The rash became darker. Sir John Moore saw him in consultation, and recommended his removal from the ward, as he looked on the case as one of typhus. Professor White examined the blood-serum and found that Widal's reaction took place with a one in twenty-five dilution. During the following days, his condition became worse, the diarrhoea more frequent, still neither pain nor tympany; his spleen was distinctly enlarged. He now refused nourishment, became wildly delirious, having to be held down; he passed his faeces and urine under him unconsciously. He got black coffee and hypodermics of strychnine, but no alcohol. He died on the eleventh day after admission to hospital. The autopsy revealed an enlarged spleen and a condition of inflammation of the mucous membrane throughout the length of the small intestine, but no enlargement or ulceration of Peyer's patches.

Professor A. H. WHITE, Hon. Sec. of the Section, said the small intestine did not present the ordinary lesions of typhoid fever; the whole mucous membrane was inflamed. The spleen was enlarged, and from it he obtained a pure culture of an organism which, though at first sight appeared to be the typhoid bacillus, he

now considers to belong to the *B. enteritidis* group. The organism is a motile bacillus, which decolorises by Gram, and does not liquefy gelatine nor coagulate milk; it ferments glucose, but not glycerine. These, and other points, Professor White demonstrated by the exhibition of about twenty different cultures on various media of this organism and similar cultures of the typhoid bacillus, bacillus coli, and two known varieties of the *B. enteritidis* kindly given him by Professor O'Sullivan. Unfortunately, he did not immunise an animal against this organism, but hoped to do so in order to determine, if possible, to which of the varieties of the *B. enteritidis* group this organism belongs. In this connection, it should be noted that the blood serum from some typhoid patients gave a clumping reaction with this organism at low dilutions only, while the serum of this patient gave a reaction with typhoid bacilli at one in twenty-five but not at one in fifty. Professor White then recounted a number of outbreaks of serious illness following on the eating of meat containing these organisms, in many of which deaths resulted, and gave more especially an abstract of Durham's work on the subject. He looks on the present case as one not of typhoid fever but of fever due to a bacillus having all the morphological, cultural, and pathogenic characters of the *B. enteritidis*, and suggests that possibly some of the milder and shorter cases of fever may be due to this or some similar organism.

Professor McWENNEY desires to congratulate Professor White on his large and beautiful series of cultures. His paper raises many interesting points of which, however, he will but touch on a few. (1) The constancy of character of these organisms. They are subject to great variety, and they cannot place much importance on slight differences. He inclines to the idea that the Gärtner organism occupies an intermediate position between the typhoid bacillus and coli bacillus. He regrets that Professor White had not immunised an animal against this bacillus; until this is done he has not shown that the organism is that of Gärtner. The case related in its clinical aspects had a striking resemblance to a series of six or eight cases brought forward by Chiari, at the International Medical Congress, Moscow, in which there were no typhoid lesions, but in which splenic puncture obtained micro-organisms which gave typhoid infection. He looked on the case as one of typhoid septicæmia due to an aberrant bacillus.

Dr. COLEMAN thought the authors were carrying the refinement of diagnosis too far. His recollection was that in Chiari's cases the micro-organisms were obtained from the gall-bladder.

Professor McWENNEY: From both the spleen and the gall-bladder.

Dr. BAWLEY: The absence of ulceration in Peyer's patches does not exclude typhoid fever. Mann has drawn attention to this fact. Is it characteristic of Gärtner's bacillus not to cause ulceration?

Professor WHITE had not much to say other than to thank the members for the reception given to his paper. With what the President has said he agrees in the main; but he considers the Gärtner group of micro-organisms as distinct organisms, not aberrant forms. If this theory is accepted, then the case is not one of typhoid fever. The organism found is, he believes, undoubtedly a *B. enteritidis*. He will, however, immunise an animal. He did not examine the gall-bladder because he had not got it. He was aware that there are a number of cases of typhoid fever without intestinal lesion recorded. Many of them, however, had not been proved, or had, bacteriologically, only been imperfectly proved. Some cases, however, had been completely proved, and in these typical typhoid bacilli were found. Such cases alone should be accepted as typhoid septicæmia. In his opinion they cannot have too refined a diagnosis. He is not aware whether ulceration may follow on bacillus enteritidis infection.

Professor C. Y. PEARSON, of Cork, then exhibited a SARCOMATOUS OSTEO-CHONDROMA OF FEMUR REMOVED BY DISARTICULATION AT HIP.

C. C., æt. 57, farmer, married, some family. Family

history good. Always healthy himself, and has had no previous illness. About eight years ago, had a fall from a ladder, a distance of 11 feet, and landed on his feet. About two years after this he noticed a small swelling on the front of his thigh at the lower part. This was about the size of a marble, hard, and unaccompanied by pain. It gradually increased in size, and in another two years it was of such a size that he had to get his trousers enlarged for it. At this time (about four years ago) he was seen by the late Dr. O'Sullivan, who, after consultation, advised amputation; the patient refused to consent, and returned home to the country. Up to this time he had never suffered much pain. On August 17th, 1901, he was again admitted to the North Infirmary. The tumour had by this time assumed large dimensions, and was causing severe pain. It was of almost stony hardness, and measured 31 inches in circumference at its widest part. The skin over it presented numerous dilated veins, and a cutaneous eruption of a lichenous character. The leg was much swollen and oedematous. There were two glands in the groin of stony hardness and about size of a walnut. Operation performed August 22nd. The femoral vessels were exposed by anterior vertical incision, and ligatured above and below the glands which were then excised. The amputation was then completed by a socket-shaped incision, all vessels clamped as divided, no tourniquet or digital pressure being employed. The patient made a good recovery, but returned in April, 1902, ailing with severe abdominal pain, and was found to have a tumour with communicated impulse in the epigastrium; behind was a large gland with secondary deposit; also an enlarged gland near external iliac. The tumour was a periosteal osteochondroma, sections of which showed ossification in cartilage and the sarcomatous tissues. A section of one of the glands showed large-cells, with active nuclei resembling squamous epithelium, but believed to be cartilage cells.

Professor C. YELVERTON PEARSON also showed a breast with large encapsuled tumour, which he had removed from a girl, *et.* 18. It had commenced five months previous to removal, and had rapidly increased. There was no enlargement of axillary glands, but marked engorgement of the veins. Microscopic examination showed it to be a papillomatous form of adenoma, with penetration of the acini.

Professor McWHEENY said that Professor Pearson had brought before them very interesting specimens. Sarcomata are usually infective through the blood current, though cases are on record showing that the lymphatics sometimes convey the infection. In his experience the enlarged lymphatics usually disappear after operation. The cells seen in the section exhibited by Professor Pearson are remarkable, being large, cartilaginous, with active nuclei.

Professor BENNETT congratulated Professor Pearson on the successful removal of such a large osteoid sarcoma. He found that such growths taking their origin from the periosteum are as a rule of the more malignant type. The case is further interesting from the considerable time the tumour existed before it gave evidences of malignancy, and it is much to be regretted that the poor man did not get operated on years before he did. Malignant tumours of this character usually infect the abdominal organs, but the most frequent site of infection is the lung.

Dr. BLAYNEY desired to draw attention to some very interesting statistics of the recurrence of sarcomata that have recently been published, showing a percentage of ninety. The prognosis is decidedly bad in such cases. It has, however, been recorded in the paper to which he has referred that cases in which suppuration occurred had a smaller percentage of recurrence of the disease than any others; and some surgeons have recommended that hypodermics of the toxin of the bacillus prodigiosus be injected into such tumours to promote suppuration, and that the production of pus during healing, after operation, be encouraged.

Professor PEARSON thanked the Section for the kind reception that his paper had got. He did not inject Coley's or any other fluid in sarcomatous tumours; he thought the methods recommended savoured of trifling

with human life. He waits and watches results before adopting extraordinary measures. He omitted mentioning that all the muscle tissue of the leg below the site of the tumour had undergone colloid degeneration. The Section then adjourned.

OBSTETRICAL SOCIETY OF LONDON. MEETING HELD WEDNESDAY, MAY 7TH, 1902.

PETER HORROCKS, F.R.C.S, President, in the Chair.

MYOMA AND FIBROMA OF THE UTERUS.

MR. ALBAN DORAN showed specimens to illustrate his contention that fibroma and myoma of the ovary were not necessarily the same thing. The first specimen was a double tumour removed from a single woman, comprising a cyst which was obviously ovarian, while underneath was another tumour absolutely solid. The ovarian ligament ran well on to the cyst and on to the tumour, which bulged from its lower part. Section of the latter showed pure muscle cells with hardly a trace of fibrous tissue, exactly resembling a specimen which he had shown before the Society and which figured in the "Transactions" of 1888. The other specimen was a pure fibroma of the ovary from a woman, *et.* 55. This was shown to consist of pure white fibrous tissue.

Mrs. STANLEY BOYD also showed a large fibroma of the ovary removed from a woman, *et.* 50, who two years before had noticed some enlargement of the abdomen and difficulty in micturition. Three months before she had seen her the growth had become more rapid, and when seen it reached two fingers' breadth above the umbilicus. It was perfectly movable. The uterus could not be defined apart from the tumour, and it was diagnosed to be a fibroid of the uterus. At the operation she found that it occupied the position of the left ovary, and was connected with the uterus by a pedicle two inches long. It was removed along with the tube which was healthy. By a curious coincidence she had operated on this patient's younger sister some years previously for fibroid of the uterus.

Mr. STANLEY BOYD showed a tumour removed from a woman, *et.* 47, married seven years, but who had never been pregnant. The periods had always been very free, but since two years they had become more excessive, leaving only a fortnight free in each month. The pedicle occupied the place of the right ovary, and the uterus and tube were normal.

FIVE SPECIMENS OF FIBROID TUMOUR OF THE OVARY, WITH OBSERVATIONS ON THEIR PATHOLOGICAL ANATOMY.

Dr. JOHN S. FAIRBAIRN read a paper in which he directed attention to the descriptions of these growths as given in the text-books and monographs on the subject. The general statement is that these tumours are formed by hyperplasia of the whole stroma, so that the organ is converted into a hard tumour retaining more or less the original shape of the ovary. Five specimens, varying in size from a small growth the size of a hen's egg up to a large tumour of over four pounds in weight, were described in detail. In all of them the new growth had arisen within the ovary, and affected only a portion of the stroma, leaving a considerable part of the organ as a separate and easily recognisable structure. The microscopic appearances were also noted, and a short clinical history of the cases from which they were obtained was added. After looking through a large number of recorded cases of fibroma and fibro-myoma of the ovary, some fifteen or sixteen were selected as similar to those described in the paper, and a short abstract of them was given. When such specimens have been shown at societies, they have given rise to some discussion from the unusual persistence of a portion of the ovary. The number of instances quoted, together with the five specimens under review, is sufficient to show that the descriptions usually given are misleading. While the difficulty of detecting unstriated muscle cells among fibrous tissue cells is acknowledged, the evidence of a comparative examination of sections from these tumours appears to be in favour of their being considered fibromata. The sections provide a very good opportunity of

contrasting the minute structure of the growth with the ovarian stroma from which they have originated; the results of such a study are adduced in favour of considering these firm hard growths of the ovary as simple fibromata, and not as fibro-sarcomata. The question of these tumours arising from a chronic oophoritis was discussed very briefly, and the importance of the tunica albuginea in forming a strong covering to ovarian growths was pointed out. In conclusion, the fibromata of the ovary were divided into three classes for purposes of description:—(1) The ovary is entirely replaced by the new formation. This occurs in small as well as large growths, and therefore does not depend on the size to which the growth has attained. (2) A local growth of the stroma, leaving part of the ovary unaffected, except by compression. The growth tends to remain within the capsule of the ovary. (3) Pedunculated fibromata like subperitoneal fibroids of the uterus. These may either have originated in the stroma and later been extruded, or they may be growths of the tunica albuginea.

Mr. ALBAN DORAN observed that, thanks to the author's paper, they would know something in future concerning a class of growth of which they had in years gone by been remarkably ignorant, and respecting which they had held very erroneous views. They used to be taken for spindle-celled sarcomata, but the saying that solid carcinomata were commoner than solid sarcomata was based on the assumption that these tumours belonged to the sarcoma class. He thought the view as to the malignancy of these tumours was due to the fact that formerly, although they thoroughly studied morbid histology, they were imperfectly trained in normal histology, and so mistook muscle fibres for spindle cells.

Mr. BLAND-SUTTON congratulated the author upon having been successful in so short a time in collecting five specimens of this rare kind of tumour. He pointed out that the distinguishing features of these tumours were that they were encapsuled, that they were ovarian in shape, and on section displayed a whorled pattern. The age limits of these tumours differed from that of similar tumours of the uterus. The latter did not form after the menopause, whereas these tumours might apparently form at any age. He protested against the histology of a tumour being determined by a fourth year's student, who scarcely knew the use of the microscope, and his dictum produced as evidence at the Society. Thanks to the points elucidated in the paper, they could now turn their backs on histology and in future, whenever they removed a tumour of this kind, they would bisect it, and if they found the whorled appearance they would group it among the non-malignant tumours forthwith. He observed that the author had rescued these formations from a group of tumours which had a very bad character, and he hoped he would continue his rescue work.

Dr. GRIFFITH pointed out that the corpus fibrosum was the ultimate result of a corpus luteum. He had seen them in great numbers in an ovary, producing some enlargement, though nothing comparable to the tumours that had been shown them. Another kind of enlargement of the ovary of which no mention had been made was that due to an overgrowth of the stroma, a form which was often met with in performing hysterectomy.

Dr. BRIGGS, of Liverpool, observed that one result of the paper would be to direct greater attention to fibromata of the ovary than had hitherto been accorded. He thought there was still a disposition among gynaecologists to regard sarcoma of the ovary as very common. All the patients he had operated upon for such tumours, as recorded in his paper, were still living, and since then he had added eight more to the list. One of these was from a girl, *æt.* 18, and the appearance was that of brain substance of the tumour; indeed, it looked very like a sarcoma, but that girl was still alive, and engaged as a hospital nurse.

Dr. SPENCER admitted that he had formerly held that a fibroid of the ovary was circumscribed by the ovary, but he had since met with enormous tumours. He had three specimens, one of which he thought clearly showed the origin of an ovarian fibroid from a corpus luteum.

LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MAY 2ND.

The President, Mr. E. CRESSWELL BABER, F.R.C.S., in the Chair.

CLINICAL MEETING.

Dr. A. BRONNER showed macro- and microscopic specimens of a large papillomata of the left maxillary antrum, which had caused destruction of the bone, and was accompanied by an offensive discharge. It had been twice removed with a snare, and the second time without recurrence.

Dr. WALTER DOWNIE showed (1) a specimen of sarcoma of the right tonsil from a woman, *æt.* 58, which was enucleated in September 1899. The patient remained in good health and without local discomfort until October, 1901, but she now had new growths in palate, pharynx, and infra-auricular region. (2) A specimen from a man, *æt.* 33, consisting of the soft palate, fauces, pharynx, larynx, and gullet, the seat of an extensive round-cell sarcoma, many secondary tumours in other viscera. (3) A large fibrous growth (removed November, 1892) from the naso-pharynx of a boy, *æt.* 11, who a year later developed symptoms of sarcoma of the left maxillary antrum. The left superior maxilla was excised and no further recurrence had taken place. (4) A large fibrous growth (removed February, 1901) from the naso-pharynx of a boy, *æt.* 14, followed by continued improvement in health and with no local recurrence.

Dr. J. DONELAN showed a case of laryngeal stenosis in a man, *æt.* 50, resulting from a large syphilitic ulcer of the left side of the larynx. The patient had been shown twice before, on which occasions the diagnosis had been doubtful. Dr. Donelan also showed a case of syphilitic contraction of the posterior pillars of the fauces in a man, *æt.* 44.

Dr. HERBERT TILLEY showed a case of complete occlusion of the right nasal vestibule in a man, *æt.* 32, following the insertion of a strong styptic for the arrest of epistaxis. The septum was deflected to the right, and Dr. Tilley said he proposed to remove the scar tissue and at the same time to perform Asch's operation on the septum. Dr. Tilley also showed a case of advanced destruction of the intra-nasal structures associated with suppuration of the right maxillary sinus, and invited opinions as to whether such a condition might arise independently of syphilis as a result of septic infection of the nasal mucosa.

Dr. H. L. LACK showed a case of great symmetrical thickening of the upper and anterior part of the nasal septum in a man, *æt.* 38, who had been under constant treatment for the past twelve years for nasal obstruction. The thickening was so great that it had been diagnosed as a cyst of the septum. It had been cut away and cauterised many times, but had always recurred. Dr. W. Hill and Sir Felix Semon said that they had great difficulty in preventing the recurrence of similar swellings. Dr. Lack also showed a case of inherited syphilis of the nose, pharynx, and larynx, with complete occlusion of the anterior nares in a boy. The appearances in the pharynx and larynx clearly simulated lupus, but the ulceration which had at first existed about the right of the anterior nares had healed under iodide of potassium, leaving complete atresia. The left nostril was already occluded.

Dr. J. W. BOND showed a case of large laryngeal growth in a woman who had suffered from huskiness of the voice for ten months. There was no history, sign, or symptom of either tuberculosis or syphilis. The growth involved the right side of the larynx, was red, and firm to palpation, and extended from below the cord to the level of the tip of the epiglottis. There was much diversity of opinion as to whether the swelling was the result of tuberculous infiltration or whether it was sarcomatous.

Dr. ST. CLAIR THOMSON showed a case of glosso-labial laryngeal paralysis, with complete paralysis of one cord and abductor paralysis of the other. Dr. Thomson had been able to watch the case from an early stage. There had been thickness of speech for twelve months. In

November last paresis of the abductor muscles was noticed, but one month ago there was double abductor paralysis. At the present time there was complete paralysis of the left cord and abductor paralysis of the right.

Dr. E. LAW showed a case of excrescences or incrustations or chalky deposits low down in the trachea. The patient had suffered from osena since childhood, but that at the present time was practically cured, only a small crust being noticed in the post-nasal space. She complained now chiefly of a constant hacking cough. On examination, a number of papillomatous excrescences or incrustations or crust-like deposits were seen low down in the trachea; a large one with ragged edges on the right side and a number of smaller ones dotted in an annular or crescentic arrangement around the trachea. Members were invited to express opinions as to the diagnosis. Mr. Waggett, who had observed the case under strong illumination for the purpose of making a drawing, ventured on a diagnosis of papillomata. Dr. Lack and Sir Felix Semon were both of the opinion that the excrescences observed were due to crusts.

Mr. R. LAKE showed a case of tuberculosis of the larynx occurring in a man, *æt.* 30, in which the epiglottis had been removed by means of the galvano-cautery snare. The stump had healed quite satisfactorily. Mr. Lake also showed a case of tubercular perichondritis; the thyroid cartilage was exposed by an external incision and a yellowish-white semi-transparent mass was found separating the perichondrium from the cartilage. This was carefully removed.

Dr. L. H. PEGLER showed a case of geographical tongue occurring in a boy, *æt.* 14. Mr. F. H. Tod showed a case of syphilitic necrosis of the intra nasal structures exposing to view the openings of the sphenoidal sinuses on each side and of the posterior ethmoidal cells on the left. There was some difference of opinion as to whether the openings seen were the normal ostia sphenoidalia or whether they were adventitious.

Mr. E. B. WAGGETT showed a case of cystic adenoma of the pyramidal lobe of the thyroid occurring in a woman, *æt.* 43, who first noticed a lump in the neck six years ago. It had recently increased to double its former size, and had become painful, evidently the result of hæmorrhage into the cyst.

Special Article.

DR. DOVER AND HIS POWDER.

AN interesting sketch of the career of Dr. Dover, whose powder has made his name a household word, appeared in a recent number of the *Chemist and Druggist*.

Dover's Powder, says our contemporary, which secured the tiniest reference among the seven personally named remedies of the German Pharmacopœia quoted from the *Apotheker Zeitung* the other day, had been famous 150 years when tuberculinum Kochi came into the physic market, and few there are who would not back the old compound against the young one as a stayer yet. "Thomas Dover," says the German journalist, "was a London doctor, and died in 1741." That is all he tells of him; what a generous record! Old Dover was no *savant*. He discovered no bacillus; he was a good way on the road towards quackery, and yet I fancy his life is better worth narrating than are those of half of the famous men of medicine stamped with the hall-mark of any university whatsoever.

"The Ancient Physician's Legacy to his Country—Being what he has collected himself in Forty-nine Years' Practise. Or an Account of the Several Diseases incident to Mankind, described in so plain a Manner that any Person may know the Nature of his own Disease. Together with the several Remedies for each Distemper faithfully set down. Designed for the Use of all Private Families." That was Thomas Dover's sole contribution to literature, and therein his famous formula is contained. It was published in 1732, when he was past seventy, and he lived nine years longer. But Thomas felt he had a message to deliver, and he had but little faith in the "clan of prejudiced gentlemen," as he termed the Royal College of Physi-

cians. They returned his contempt; or more probably they began the squabble, for Dover tells in his book that they had referred to him in derision as "the quicksilver doctor." But it was a title in which he gloried. He had immense faith in quicksilver, "this precious jelly of mettals as it may be called." It makes a pure balsam of the blood, he says; that is why it cures venereal complaints. You all give it, he adds, but you disguise it. I give it in an honest, open manner. You give it combined with sulphur, the worst excipient you could find, in the form of Ethiop's mineral. That is like striking a man with a sword in the scabbard. They (the clan of prejudiced gentlemen) say it is a poison. "Their opinion is a sign they have travelled far at home." He advises them to "take a trip to Hungary and visit the mines where the quicksilver is dug. They may there see slaves working entirely naked to prevent them stealing the mettall." But these slaves, it appears, dodged their taskmasters "by swallowing every day so much that they buy a choppin of drink with it at night."

Dover was born somewhere in Warwickshire in 1680. How he got his medical training is not known, but some time in his youth he lived in the house of the famous physician Sydenham. There he had small-pox, and his treatment is worth recording. First he was bled to the extent of 22 ozs.; then he had an emetic. It was January; he had no fire in his room, the windows were always kept open, and the bedclothes were only allowed up to his waist. The medicine he took was twelve bottles of small beer, acidulated with spirit of vitriol, every twenty-four hours. Having resisted both the disease and the treatment he is first heard of in practice at Bristol in 1684. He plodded on there till 1708, when at the age of forty-eight he set out with a privateering party on a voyage round the world. They had two ships, the *Duke* and the *Duchess*. Captain Woodes-Rogers, who has left an account of the expedition, was in chief command, and Dover, who had charge of the *Duke*, was his second. He must have been on the sea in his early life, or he would hardly have been chosen to command a vessel. The buccaneers were away from England three years, and they came back with a Spanish frigate of twenty-one guns and lots of loot. Among the other events of the voyage was one of world-famous importance. On February 2nd, 1709, Dover touched at the island of Juan Fernandez, and brought away from it Alexander Selkirk, who had been there alone four years and four months, and who was the prototype of the immortal Robinson Crusoe.

A few months later the expedition landed at Guayaquil, in Peru. Having sacked the city and stored their plunder in the ships, the sailors slept in the churches, and Dover records quaintly how they were annoyed by the smell of the corpses. For plague was raging in the place at the time, and the victims were laid just below the floor with only a plank or two to cover them. Forty-eight hours later, after they had again put to sea, a large number of the sailors were attacked by the disease. One hundred and eighty of them altogether had it. Dover, who had four surgeons under him, ordered them to be bled freely, and he says about 100 ozs. of blood was taken from each man. The surgeons went round and started the bleeding, and only stopped it when they had made their rounds. Then he gave them spirit of vitriol, and only seven or eight died. Returning to England, Dover practised in Cecil Street till 1728, when he is again missed for two or three years. From 1731 to 1736 he lived in Arundel Street, Strand. There he wrote his book, in the preface of which he quotes Dr. Radcliffe's opinion that it is expedient that young gentlemen entering our profession should travel. "If travelling be necessary to make an accomplished physician," Dover remarks, "I am very sure that I have travelled more than all the physicians in Great Britain put together."

His diaphoretic powder is prescribed in his book in a chapter on gout. The formula differs, but the resulting compound is practically the same thing that we call Dover's powder. The original formula was as follows:—

Take opium 1 oz., saltpetre and tartar vitriolated each 4 oz., liquorish 1 oz., ipecacuanha 1 oz. Put the saltpetre and tartar into a red-hot mortar, stirring till they have

done flaming. Then powder them very fine; after that slice in your opium; grind these to a powder, and then mix the other powders with these. Dose: from 40 to 60 or 70 gr., in a glass of white-wine posset going to bed, covering up warm, and drinking a quart or three pints of the posset-drink while sweating.

In two or three hours at furthest the patient will be free from pain; and, though before not able to put his foot to the ground, 'tis very much if he cannot walk next day. The remedy may be taken once a week or once a month.

A side-light on the relations between doctors and apothecaries in the early days of the eighteenth century is thrown by Thomas Dover's treatise. In a chapter on ague (for which he says bark is the best medicine known to mankind, though he wishes he could have the resinous quality of it separated from the earthy part) he remarks that he cannot prescribe to please the apothecaries. He cannot bring a fever case to £3, though he has known apothecaries who have run up their bills in such cases to £40, £50, or £80. Every time a physician writes, he says, it is supposed to put 10s. or 12s. in the apothecary's way. Then, as a postscript, he prints the following on the last page:—

N.B.—Having taken notice of some errors in the practice of other physicians, I shall frankly own one in my own; I have hitherto been too zealous in recommending one particular apothecary, but am resolved, for the future, to let all my patients make use of any apothecary they like best, which I think is but doing justice to the gentlemen of that profession.

Whether this was a really honest repentance, or whether the one particular apothecary had offended Master Dover, doth not appear.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, May 11th, 1902.

THE TREATMENT OF LUPUS AND PSORIASIS.

M. HALLOPEAU, at the last meeting of the Dermatological Society, read a paper on the treatment of lupus and psoriasis by permanganate of potash, in which he pointed out that although some specialists believed that permanganate of potash was powerless against lupus, he had recently treated a woman for one of the gravest forms of the disease with that agent, and the success was complete. He presented several other cases in which the cicatricial tissue was very extensive, and he did not doubt that by persevering in the application of the salinated solution he would obtain a complete cure. In psoriasis he obtained also considerable satisfaction by applying compresses to the lesions of a solution of permanganate 0.3 to 1 per cent., according to the tolerance of the patients.

BURNS.

According to M. Goldstein the same salt (permanganate of potash) in saturated solution painted on burns is superior to all other treatment. By it the pain is quickly relieved and healing rapidly follows. As the permanganate when in contact with organic substances becomes decomposed into caustic potash, oxygen and oxide of manganese, M. Goldstein believed that the potash and the oxygen produce the anæsthesia by local caustic action, while the oxide of manganese ensures the asepsy of the wound.

CHOREA AND ARSENIC.

M. Fabel has recently passed in review the arsenical preparations employed in the treatment of chorea, and which are in order of importance Boudin's solution—

(1-1000), Fowler's solution, arseniate of soda and cacodylate of soda. In children of eight to ten years old the daily dose of Boudin's solution, to commence with, is a drachm or a drachm and a-half and gradually increased by half a drachm until symptoms of intolerance appear (vomiting, diarrhoea, pricking sensations in the limbs), at this period the choreic agitation begins to yield, and after a rest of four or five days the arsenical solution is prescribed again, but in decreasing doses. Prof. Cornby prefers to commence with large doses, two drachms and a half daily, and rapidly increase until an ounce is reached, or nearly one grain of arsenious acid. M. Fabel considers this treatment too heroic, and positively dangerous. The Fowler solution is given in subcutaneous injections by the Lyons school, it being easy to execute and improving rapidly the state of the patients; but, in spite of these advantages, M. Fabel prefers the usual internal administration as recommended by Reese, who gives from three to four drops twice a day to children of from eight to ten, and this dose need never be exceeded during the whole treatment.

The arseniate of soda has been employed particularly by Gillette and Cadet de Gassicourt. Gillette's formula is as follows:—

Arseniate of soda, 0.05 gramme.

Water, 500 grammes.

A teaspoonful contains the fiftieth part of the active principle. From one to two teaspoonfuls are given to commence with, and gradually increased the following days until intolerance sets in. Cacodylate of soda is generally employed subcutaneously according to M. Garraud, of St. Etienne; its effects are certain and its employment without danger. M. Lannois considers that it should be preferred to any of the metallic preparations.

SYPHILIS.

Cyanide of mercury, } 15 grains.
Hydrochl. of cocaine, }
Water, 3iij grains.

Inject a full Pravaz syringe every two days into the muscle of the gluteal region. A series of thirty injections are required for a complete cure.

The advantages of this treatment of secondary syphilis and the later manifestations of the disease over the ordinary methods of treatment are: it is painless, produces no local reaction, and it is rapidly effective.

THE BLIND IN FRANCE.

Dr. Troussseau presented a report to the Ophthalmological Society from which it appears that the number of the blind in France reaches the high figure of 31,966, or a proportion of 8 to 10,000 of the population. This proportion considerably exceeds that of Denmark, Sweden, Switzerland, Austria, and notably Holland, where it is exactly 4.46 per 10,000. According to Dr. Troussseau, two-thirds of these unfortunates might have escaped the terrible deformity if proper precaution had been taken. Purulent ophthalmia was one of the chief causes of avoidable cecity. Professional wounds of the eye were another cause that might be avoided. Workmen at such trades as stone-cutting, filing, grinding, &c., and all those employed at steel and iron works should be compelled to wear protective spectacles.

A third great cause of cecity, single or double, was myopia. Parents should pay more attention to the eyes of their children during the school period.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, May 10th, 1902.

At the Surgical Congress, Hr. Petersen, Heidelberg, gave an address on

RECURRENCE IN CANCER.

Recurrences or secondary tumours at the site of operation arose when epithelium was present that had already undergone changes, and later took on the character of carcinoma. They were frequently caused by disease being left behind, and also by previous implication of the glands of the region, such diseased lymph vessels being often found on section at a considerable distance from the original disease. Inoculation with the disease was certainly possible in this way. Intentional implantation of living carcinoma was very rarely successful. Inoculation recurrence was therefore not impossible, but precaution should be exercised in the diagnosis, and this mode of origin must only be accepted when all others were excluded. The recurrences had this in common that they all proceeded from cells that were undergoing cancerous degeneration. In other cases the recurrence was not restricted to the spot, but occurred at parts locally removed from the original site. These pluricentral growths also frequently occurred at different times; they were, therefore, pluritemporal, as in the case of the epithelial tumour of the ovaries, where it was found in different spots in the one stage, or in different stages. These conditions were better observed in benign tumours that developed more slowly. In the neighbourhood of carcinoma were tissues which showed commencement of the disease, though this might escape the naked eye. The epithelium was only anaplastically changed and overlooked at the operation. Frequently the epithelium was not changed, and only became so later on. The period of time between the occurrence of the original tumour and recurrence varied greatly. Deferred recurrences were specially interesting. There were also peculiarities in the original growth that influenced recurrences. Encapsulation processes might retard recurrence and further it was not every cancer cell that when left behind led to return of the disease. Such cells sometimes underwent retrogressive metamorphosis as in lung and liver carcinoma. More delayed recurrences were to be attributed to pluricentral forms of the disease.

Prof. Wennebach, of Groningen, has a paper in *Therapie u. Gegenw.* 2/1902 on

AN EFFECTIVE TREATMENT OF SEPTIC ENDOCARDITIS.

The desideratum for the cure of an infective ulcerative endocarditis is a harmless antiseptic which, when introduced into the blood current, is strong enough to kill the bacteria circulating in it and to disinfect the diseased spot on the endocardium. Such a remedy the author believes Crede's argenticum colloidal to be, introduced into the market under the name of collargol. It can not only be used externally and internally, but it may be injected in a 1 or 2 per cent. solution directly into the blood current. When one can overcome the dread of injecting such a thick-looking material into the system one becomes convinced of its harmlessness. The author reports two cases that speak in favour of the external efficacy of the remedy. It should be used

early in the disease, and the author does not see why it could not also be used in cases of rheumatic endocarditis, which must really be of bacterial origin.

At the Surgical Congress, Hr. Korte, Berlin, discussed

THE PATHOGENESIS AND TREATMENT OF PERITYPHILITIS AND PERITONITIS,

introducing a report of sixty cases of subphrenic abscess. Subphrenic abscess occupied an unusual position, from its etiology, its not easy diagnosis, and its treatment. As regarded etiology, its more frequent cause was inflammation of the vermiform appendix; it was so in nearly the half of the speaker's cases. In consequence of this origin the abscess was nearly always on the right side. Other causes were ulcers of the stomach and duodenum (ten times out of the sixty). Gunshot wounds were also a cause. It was more frequently situated between the left lobe of the liver and the stomach, and most frequently contained gas. Stomach contents were not found in his cases. Five of these cases recovered and five died. At the autopsies no direct communication was found between the abscess and the stomach, but only an indirect one, that might be blocked. The abscess might also arise from the liver or bile passages—five cases, and here the prime cause might be echinococcus of the liver and gall-stones. These cases were, as a rule, unsuitable for operation on account of the multiple collection in the liver—five deaths. The abscess originated in the spleen in five cases with three recoveries and two deaths. Four from empyema—three recoveries and one death; four after perinephritis, with two recoveries and two deaths; two from disease of the ribs, both recovering. The diagnosis was based on the history of inflammation of the organs from disease, of which experience taught us such abscesses had their origin, and next on displacement of neighbouring parts. When empyema was the cause it could only be determined by operation. The operation should be performed quickly after exploratory puncture, as general infection readily took place. As regarded operation, the peripleural incision, and that along the margin of the ribs, were to be considered. With the first-named we had to reckon on the possibility of an empyema developing.

The following precautions were taken to prevent infection of the pleura. A portion of pleura the size of a five-shilling piece was sutured off and the operation performed within this space. A secondary empyema followed in four cases. In fifteen cases the incision was at the margin of the ribs and four times in the middle line. In order to ensure a good result the patient should come into the hands of the surgeon early.

The total number of operations performed by the speaker was sixty, of which forty recovered and twenty died.

		Recovered.	Died.
Peripleural incision	41	27	14
Costal margin incision ...	15	10	5
Middle line incision	4	3	1
	60	40	20

Royal College of Physicians and Surgeons, Ireland.

The following candidates have been admitted to the Diploma in Public Health of the Colleges:—W. E. Burton, F. J. de Lisle, M. McGrath, E. McCombe, J. E. M. O'Ferrall, Gibb Smith, A. E. Robb, A. Williams

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, May 10th, 1902.

HYSTERIA.

At the "Gesellschaft der Aerzte" Yörök showed a young woman, æt. 18, with nineteen needles in the left leg which she had inserted herself. They were readily seen by the aid of the Röntgen rays. He purposed cutting down and removing them forthwith.

MULTIPLE CARTILAGINOUS EXOSTOSIS.

Spiegler demonstrated a case of multiple cartilaginous exostosis of the humerus, scapula, and costal joints, as well as several joints in the left foot. These commenced to form about the seventh year of age, and gradually increased until puberty, when osseous growth ceased. There was no history of rachitis, but rather an inhibition of osseous growth, particularly in the left forearm. The mother of the patient, as well as several other of the ancestors, presented deformities or malformations.

ERYTHROMELIA.

Ehrmann next showed a patient, æt. 20, with a rare form of erythromelia of the left leg, which commenced twenty years ago with redness and thickening of the skin. Since that time the cutaneous surface from the nares to the malleolus of the left leg had acquired a peculiar colour with a smooth, thin integument. About the knee the skin had the appearance of atrophic cutis idiopathica, lower down that of scleroderma. Sensation was not impaired. Electrical stimuli, owing to the cutaneous atrophy, was increased. This, he thought, was a doubtful case, and he could not decide whether the vessels were at fault, whether it had a toxic origin, or was due to erythema angio-paralyticum of Neumann, or to simple toxic erythema.

Ganz said this was certainly a very unusual case, as the disease was usually bilateral, though not to the same extent and not unilateral as in this patient.

Neumann thought it was premature to affirm a cognate relationship between the symptoms of erythromelia, idiopathic atrophy of the skin, and scleroderma.

Weinlechner recalled the case of an elderly woman with atrophy of the skin which was occasioned by contraction of the knee-joint, and asked if the same cause might not be incriminated in the case before them. Ganz replied to this by saying that the condition might arise in a case of scleroderma but not in a case of atrophic cutis idiopathica.

Kreibich recalled the case of an old woman whom he attended with a shiny swelling over the instep, which he fixed, and which afterwards became contracted. Kaposi thought this case of Kriebich was similar to the knee-joint case, and that the reddening and desquamation were nothing else than pityriasis rubra at the stage of atrophy.

Ehrmann said he quite understood why contractions were not present in erythromelia and idiopathic atrophy, while present in scleroderma, viz., that the first two were simply atrophy of the parts, while the latter sclerotic condition involved the subcutaneous and fibrous tissues.

FOLLICULAR OR PERIFOLLICULAR ABSCESSSES.

Spitzer presented a patient whose skin was literally covered with scars, large and small, reminding one of syphilitic or scrofulous lesions. Histological examination proved it to be due to a follicular or perifollicular

process, producing an enormous dilatation of the folliculi, which culminated in abscesses. In these were found pus and detritus, containing the white purulent cocci.

PNEUMOTHORAX.

Hofbauer presented a case of acute pneumothorax which had appeared within three weeks without fever or other complication. Neither clinical history, Röntgen rays, nor physical examination afforded an adequate reason for the morbid phenomenon.

EPICARINS.

Winkler has been using epicarins in the dermatological department with apparent success in seborrhœa capitis and shedding of hair. His prescription is:—

R. Epicarini	...	...	50 grammes
Spt. æther sulp.	...	15.0	"
Spt. vini gall	...	800	"

M

Sig.—Hair wash. To be used daily by rubbing well into the scalp.

He also uses an ointment made with soft soap.

CARCINOMA OF PENIS.

Englisch next read a lengthy communication on cancer of the penis. In the protocols of Vienna for the years 1892 to 1898 inclusive there were 540,539 patients treated, 12,607 suffered from carcinoma, 81 of whom were suffering from carcinoma of the penis (1.78 per cent.). In the literature of the subject he found 528 cases, 12 of which were minutely described. The disease appears between fifty-one and sixty years of age. The origin usually assigned was slight inflammation of the foreskin, frenulum, or glans. Congenital phymosis was noted in only 29 per cent. of the cases, which fact was opposed to the view of this being one of the factors in the ætiology of the disease.

The induration is usually preceded by œdema, hypertrophy, extraordinary swelling, or, what is more frequently the case, tubercles in the form of warts or papillomata. The usual period of development is twelve to fifteen months.

The early symptoms are local, such as frequent micturition, burning in the urethra, particularly near the orifice, with sometimes a little discharge, then the glans become swollen when the external phenomena commenced. These premonitory symptoms lasted about eighteen months. The glands of the inguinal canal, in front of the symphysis pubis, and bladder are usually enlarged. Metastases in the internal organs are very rare.

The rational treatment is amputation either with the knife or galvano-cautery, at the same time removing all enlarged glands within easy reach. Out of 465 cases operated on, 438 recovered completely (94.19 per cent.), while 5.8 per cent. went from bad to worse.

YOHIMBIN IN THE TREATMENT OF IMPOTENCE.

Yohimbin seems to be efficacious as a remedy for impotence. Silberstein records several successful cases. It may be remembered that this drug was brought before the profession some time ago as a powerful agent in impotence, but from its limited application we were cautious in its praise. It is a crystalline alkaloid, obtained from the bark of the yohimbe tree.

Oberwarth and Löwy used 0.005 to 0.015 of a gramme in the form of a hypodermic injection in dogs, which caused swelling of the testes and scrotum, followed by erection.

Eulenburg and Beeyer next used it clinically with a similar result.

Silberstein showed two patients suffering from hypochondriacal impotence, whom he had treated with yohimbin with perfect success. He records a number of chronic alcoholic paralytics with whom he obtained equally good results. Two cases of chronic bromide drinkers had their potency restored in a similar manner after one week's use of yohimbin, although the patellar reflex had been lost for a month.

The Operating Theatres.

WESTMINSTER HOSPITAL.

CHOLECYSTECTOMY.—Mr. WILLIAM TURNER operated on a man, *æt.* 31, who for nine years had suffered on and off from typical attacks of biliary colic; a fortnight previously he had had an attack which lasted twenty-two hours and then suddenly ceased, but the stone was not passed per rectum, though very carefully looked for. On admission he complained of a continuous aching pain in the epigastric region and a general feeling of malaise; he was slightly jaundiced, tongue furred, temperature normal, pulse 64; on examining the abdomen there was distinct prominence in the epigastric region, the upper segments of the recti muscles were very rigid, and there was marked tenderness at a spot two inches above and one to the right of the umbilicus; this region also was dull on percussion; the dullness extending over to the left side and seeming to correspond to the left lobe of the liver rather than to the gall-bladder; the edge of the liver could not be made out. Ether was administered and the same resistance and dullness was found as before, so a vertical incision was made from the margin of the ribs $1\frac{1}{2}$ inches on the right of the linea alba for six inches downwards; the skin, superficial fascia, and the anterior layer of the sheath of the rectus were divided, and the fibres of the muscle then separated in the line of incision; at this stage there was some free hæmorrhage from the muscular branches of the superior epigastric artery, which was controlled by Spencer-Wells' forceps and then by catgut ligatures. The posterior layer of the sheath of the rectus and the transverse muscular fibres of the transversalis were divided with a scalpel in the same line; the peritoneum was picked up with dissecting forceps and opened, and then the opening enlarged with scissors, the first finger of the left hand acting as a director. The liver was found to be enlarged, extending down to midway between the margin of the ribs and the umbilicus, the edge being turned somewhat backwards; on lifting up the edge the gall-bladder, containing numerous gall-stones, was found, rather contracted and firmly bound down by numerous adhesions to the intestines, stomach and omentum. As the conditions of the ducts could not be made out for certain, and as it was obvious that the adhesions were in a great measure responsible for the continuous aching pain complained of, these were next dealt with, being divided between Spencer Wells forceps and the cut ends carefully ligatured with fine catgut, the lower part of the wound being carefully packed with sponges. Retractors were then placed in the wound and the liver being held up by an assistant's finger, the condition of the ducts was carefully explored; gall-stones were found to extend the whole length of the gall-bladder, but none were found in the cystic duct itself, which was small; the finger was introduced

into the foramen of Winslow, and then the common bile duct was found rather enlarged but empty, and with no trace of a stone in it. Some enlarged glands were felt posteriorly behind the peritoneum, their enlargement being presumably caused by the chronic inflammatory condition around and of the gall-bladder. The hepatic ducts were next isolated and found also to be empty. The peritoneum binding down the gall-bladder to the liver was next divided first along the left side, and then the gall-bladder carefully separated from the liver and traced down to the cystic duct, which was ligatured with silk about a quarter of an inch from its junction with the common hepatic duct, then divided, and the mucous membrane touched with pure carbolic acid, and the gall-bladder containing fourteen stones removed. The cystic artery gave some little trouble, but was soon controlled by a catgut ligature. The cavity was sponged quite dry, a few oozing points being ligatured; the silk ligature tying the cystic duct was passed through a drainage tube having no side holes, this last was inserted to the bottom of the wound and brought out about the centre of the skin incision; a small plug of gauze was also packed into the raw surface of the liver and brought out alongside the tube. The abdominal wound was now sewn up in layers; peritoneum with simple continuous catgut stitch, posterior layer of sheath of rectus and transversalis muscle with the same; separated fibres of rectus by four interrupted kangaroo-tendon stitches, anterior layer of sheath with continuous fine silk and skin by two interrupted silk-worm gut sutures and three continuous blanket sutures, a small space being left about the centre for the drainage tube and gauze to come through. The drainage tube was stitched in position and the wound dressed in the ordinary manner with double cyanide gauze and wool. The operation lasted an hour and fifty minutes, but the patient stood it very well. Mr. Turner said that this case presented several points of interest; first the patient was a male and only 31, whereas gall-stones were much more common in females and after the age of 35; then the marked spot of localised tenderness about two inches above and one inch to the right of the umbilicus, which has been pointed out in books as so characteristic of stone in gall-bladder, and as being almost as commonly met with as the tenderness at McBurney's spot in appendicitis. Then again, he said, the gall-bladder itself could never be definitely felt owing to the liver being lower than normal, and its edge curled in owing to the numerous adhesions demonstrated at the operation. As regards the operation itself, he said he preferred the vertical to the transverse incision, as the rectus muscle is not damaged, but only its fibres separated, and ample room obtained by the use of suitable retractors. He pointed out that the muscular fibres of the transversalis met with posteriorly to the sheath of the rectus sometimes bother the surgeon, but they must be divided before the peritoneum is opened. The peritoneal adhesions were troublesome, as is often the case, taking time and care to deal with satisfactorily; they were mostly between the gall-bladder itself and the hepatic flexure of the colon, though some went on to the pyloric end of the stomach, omentum, and all round the common duct to the duodenum. His reasons for removing the gall-bladder and not opening and draining, he remarked, were first because the large ducts were patent and con-

tained no stones; secondly, the incurved edge of the liver practically prevented the bringing up of the gall-bladder satisfactorily to the surface; then the gall-bladder itself was not distended with bile, but had very thickened walls, and from the old inflammatory trouble was of an hour-glass shape; again the presence of the adhesions was undoubtedly giving much trouble and discomfort to the patient, and had to be dealt with, anyhow to give him his best chance of relief; and lastly, because stones are known to be formed more easily in a chronically inflamed gall-bladder, so that after removal they would have recurred if drainage only had been adopted. He thought the deep silk ligature might, if cut off and left, give rise to more adhesions and some chronic inflammation round the common duct, so he brought the end outside and passed a drainage tube over it to provide against any leaking which might occur when it came away. Mr. Turner also said that in the after-treatment he preferred rectal feeding for four or five days, and if necessary a little morphia could be given. Sometimes the presence of the plug of gauze and the drainage tube gives rise to reflex vomiting, and if this occurred the plug should be partially or completely withdrawn, and the tube pulled out half an inch. He hoped the plug would be able to be completely removed on the third or fourth day, and the drainage tube and the silk ligature in about eight to ten days. The surface of the liver, from which the gall-bladder had been removed, being left uncovered with peritoneum, a certain amount of bile was usually found staining the plug, and the patients often absorbed a little, and became a little jaundiced after the operation.

It is satisfactory to state that the patient, eight days after the operation, is going on very well; the plug was removed on the fourth day; the temperature had not been above 100°. The slight transient jaundice disappeared on the sixth day, and he has practically no pain.

"Christian" Science.

Among the fashionable forms of pseudo-science, so-called "Christian Science" has undoubtedly taken a firm hold. Recently the Hon. W. G. Ewing, who believes he owes his life to this form of "healing art" and has travelled 50,000 miles advocating its virtues, lectured to a large audience in the Queen's Hall and is reported to have claimed that in the whole life of "Christian Science" the aggregate fatalities under its practice in twelve of the United States during a period of thirty years were not equal to the deaths occurring under material medicine in any one week in the last two years in the cities of Chicago and greater New York. Certainly this does not speak well for American medicine, but we should like to know the source of the statistics on which so astounding a statement is supposed to be based.

Typhoid and Our Troops.

It is lamentable to know that enteric fever still prevails to an enormous extent among our troops in South Africa. In the expectations of peace the public readily forget the hardships and perils of a campaign. Mr. Brodrick has just given us numbers which forcibly illustrate this. The number of cases of typhoid among the troops was 1,507 in December last, 2,750 in January, and 2,122 in February, whilst the deaths were 224 in December, 396 in January, and 333 in February. It would seem that most of the cases occur among the men serving in mobile columns. While fully admitting the difficulties and making great allowance for wilfulness and "sheer cussedness," we cannot but believe that the education of Tommy Atkins in the elements of hygiene is still almost entirely neglected.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d. Half Page, £2 10s. 0d., Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 14, 1902.

PREGNANCY AND TYPHOID FEVER.

THE recent lamentable experience of an illustrious patient has directed general attention to the relation between pregnancy and typhoid fever. It is of the greatest importance to the clinician, and presents features of much moment judged from the prognostic standpoint. It has been sometimes affirmed that such physiological conditions as pregnancy, the puerperal state and lactation diminish the predisposition to typhoid fever, but there is no inconsiderable difference of opinion upon the matter. When, however, infection occurs during pregnancy, most authorities consider that abortion or premature labour is not only liable but likely. Certainly gravidity must be reckoned a most serious complication of typhoid fever. There is much discrepancy in the statement of writers with regard to the course and prognosis of typhoid fever in pregnant women. Professor H. Curschmann, in his masterly monograph, which has recently been rendered available for English readers, edited by Professor W. Oslen, deals with the available statistics. Murchison believed that the prognosis was always grave, and in an advanced state of pregnancy considered that a fatal termination to premature labour almost invariably occurs. Liebermeister had a fatal issue in one-third of the eighteen cases coming under his observation. Curschmann met with fourteen cases at Leipsic; pregnancy was interrupted in all but one, and death occurred in five, that is in 35.6 per cent. At Hamburg his results were more favourable. Of all the women coming under observation in 1886-1887, thirty-eight, or 3.4 per cent were pregnant. Of these, three went to term, and were delivered during convalescence of living children, while fourteen, or 41.1 per cent., were discharged after recovery from the attack of typhoid

fever without interruption of the pregnancy. The mortality during pregnancy was 7·8 per cent. Sacquin has collected from various sources the statistics of 233 cases of pregnancy during typhoid; abortion, miscarriage, or premature labour occurred in 150 of these, and death occurred in thirty-seven, or 16 per cent. Unfortunately in this country trustworthy statistics in regard to this matter are wanting, or are to a great extent inaccessible, and most of our text-books offer but little help. To the general practitioner and those burdened with the responsibility of such cases guiding information is much needed, and we shall be pleased to publish any trustworthy statistics which may be furnished us either from general practitioners or those who from the wider outlook of hospital experience are able to formulate prognostic indications.

THE POPULARITY OF HOSPITAL NURSES.

FOLLOWING on a paper by Miss F. M. Johnston, in the April number of the *Nineteenth Century*, on the subject of hospital nurses, in which the author takes them gravely to task for various shortcomings, there has been a certain amount of discussion in the public press bearing on the reality of the drawbacks alleged to attend their employment. Miss Johnston bears witness to the fact (?) that the nursing profession is curiously unpopular, a feeling which she believes is steadily on the increase. The gravamen of her charges is that trained nurses become hardened and indifferent to the comfort of the persons committed to their charge. Now we, as medical men, know something about nurses, and we have no hesitation in asserting that Miss Johnston has "got hold of the wrong end of the stick." We are not concerned to deny that nurses are unpopular in one sense, but so are disease and suffering in every sense. Their presence entails considerable expense, a partial dislocation of the domestic economy, and it is, so to speak, a harbinger of woe, though not of their making. If nurses, like doctors, ultimately become inwardly callous to suffering they, like the latter, usually contrive to mask the fact beneath a smiling and sympathetic countenance. This callousness is a law of nature, for existence would be intolerable if one's nervous system were to be kept continually vibrating in response to gusts of inopportune emotion. The one reproach to which the trained nurse must often plead guilty, is that of putting too great a strain on the household administration. That they do so in some instances to an unnecessary extent is in accord with one's own experience, but, short of undertaking part of the menial work themselves, it is obvious that a domestic service intended to defray the requirements of an average household must inevitably prove inadequate when this further considerable strain is thrown thereon, wherefore the Abigail cries aloud in her wrath. Moreover, it is a trifle absurd to generalise on such a subject. Nurses are not all cast in the same mould, and "it takes a lot of all sorts to make a world," even of nurses. They are

not all of the kind so forcibly depicted by Mr. Gant in his "Modern Nurse," hopelessly immoral and absolutely unscrupulous, neither are they all of the ministering angel type. The average, we make bold to say, is a satisfactory one, whatever their detractors may say to the contrary. That average is a neatly-attired, sensible young woman, fairly educated, and intelligent enough to carry out the instructions given by the medical man in charge. She may, it is true, be addicted to gossip, and she may not always have that suavity of manner and gesture which go to make the perfect nurse, but she is a precious and, on the whole, welcome figure at the bedside, and, in the majority of instances, leaves behind her feelings of gratitude for services rendered. It may be noted in passing that the harshest appreciations of the trained nurse come from women patients, indeed the period which nurses pass on the female side of hospital wards is unquestionably the most trying part of their career. The nursing profession is an institution which, if not altogether peculiar to Anglo-Saxon countries, owes its modern evolution to the Anglo-Saxon spirit, and the worst that can be said of it is that it has the defects of its virtues which are many.

IS SMALL-POX AN AIR-BORNE MALADY?

It is curious to note how in some cases practical medicine, although in many ways the most progressive of all sciences, nevertheless halts doubtfully in front of some problem apparently not of a hopelessly insurmountable nature. The inner secrets of many a plague and pestilence, for instance, have been unravelled, and mankind is well on the way towards their extinction. On the other hand the most acute scientific research has in not a few instances been baffled by elementary facts in such diseases as small-pox, measles, whooping-cough, and cancer. The case of small-pox is especially curious, as the affection presents a well-marked lesion, and its pathological and clinical features are all, or nearly all, strongly marked and characteristic. In spite of the interest which this complaint has always aroused among the medical profession, there yet remains some doubt as to the agency by which the disease is mainly spread, that is to say, whether the virus is conveyed by actual contact between the healthy and the infected or is carried by the air. The point has been hotly disputed in years past, but recently the tendency has been to reject the air-borne theory in favour of that of actual contact. One of the strongest facts adduced by the supporters of aerial convection is the prevalence of the disease among the population in the immediate neighbourhood of small-pox hospitals. Time after time careful observation has proved by means of "spot maps" marking the exact location of small-pox cases, that the majority of patients were to be found close to the hospitals in question. It was shown, moreover, that the number of cases was greater the nearer the hospitals and *vice versa*. The Local Government Board

took the matter up, and proved pretty conclusively that personal contagion could not be separated from the question of zonal incidence round small-pox hospitals. No sound conclusions, therefore, can be formed unless they satisfactorily dispose of that source of fallacy. Indeed, the trend of general scientific opinion has been unmistakably in favour of direct contagion for several years past. The air-borne theory, however, has been once again pointedly raised by Dr. Thresh, the well-known medical officer of the county of Essex. The small-pox hospital ships, as most people know, have been anchored down the Thames, off the Essex shore, during the present outbreak of small-pox in London. Dr. Thresh has found that the Orsett Union, opposite the hospital ships station, has suffered from a prevalence of the disease seven times greater than that of the rest of Essex, and two-and-a-half times greater than that of London, although previously it had been affected about equally with the rest of the county and far less than the metropolis. He then repeats the old observation of hospital incidence upon surrounding population in direct ratio to vicinity, only that the conditions are altered at Orsett by the position of the ships out in midstream. His analysis shows that the attack rate at the nearest shore-margin has been one in ten of the population, with a rapidly diminishing ratio according to distance. These and kindred facts lead Dr. Thresh to the conclusion that the infection has been disseminated by the air blowing from the hospital ships to the shore. It is not possible to feel a certain amount of sympathy with the result of his investigations, and it seems impossible to avoid the conclusion that small-pox may in some instances and to a limited extent be subject to aerial convection. Dr. Thresh has indeed put his case strongly, but he has not satisfactorily dealt with the ever-present fallacy of personal communication. Until that is done his further conclusions lack the force of logical argument. Were the air-borne theory of the spread of small-pox to be accepted as the explanation of the commonest agency at work then it would be well-nigh impossible for any conscientious local authority to find a site for a small-pox hospital. In a recent article upon this subject a writer in the *Standard*, who handles the whole subject with singular lucidity, points out that Dr. Thresh's case would be strengthened if it could be shown that the occurrence of attacks on shore coincided with the blowing of the wind in that direction, and that vessels passing on the river had also received the infection. Speaking generally, it is a matter of great practical importance to preventive medicine that this point should be authoritatively settled. Meanwhile it is comforting to reflect that the efficacy of vaccination and re-vaccination retain their proud position as the sheet anchors of prevention in dealing with this terrible scourge of humanity.

THE King has appointed Mr. Thomas Joseph Stafford, F.E.C.S.I., to be a member of the Royal Commission on Sewage Disposal.

Notes on Current Topics.

Metropolitan Asylums Board Expenditure.

THE enormous expenditure of the Metropolitan Asylums Board is assuredly a matter which should attract the attention of persons competent to discuss it. That the functions of the Board are admirably discharged is a matter as to which there can be little difference of opinion, but this virtual unanimity of opinion may possibly not obtain when the expenditure is regarded from the point of view of economical administration. Admitting that the conduct of the Chairman of the Finance Committee in issuing a statement criticising the financial administration of the Board without previously bringing it before his Committee, was somewhat irregular, the fact remains that he calls attention to some discrepancies which we should be pleased to see explained. He may well ask, for instance, why an increase of 1 per cent. in the average daily number of inmates should be held to justify an increase of 38.8 per cent. in the expenditure. Some share of the increase, it seems, is due to the abnormally rapid rise in the office expenses, and this is a point which calls for strict investigation, for we know by experience how this branch is apt to develop unless kept well under control. It would be unjust to compare the weekly cost per patient in the Board's hospitals with that of patients in the general hospitals, if only for the reason that in the cost of the Board's patients is included the repayment of interest on loans and similar surcharges which do not enter *en ligne de compte* at the public hospitals. Nevertheless it is not easy to understand why a patient at the North-Eastern Hospital costs *net* 1s. 8d. a day, while at the Grove Hospital his maintenance entails a daily expense of 3s. Criticism directed against the policy of the Board in providing accommodation in excess of probable requirements is beside the mark, because it is the obvious duty of the Board not to be found wanting at the critical moment, and all estimates of probable requirements are necessarily more or less vague and experimental.

Visitors to Small-Pox Hospitals.

THE question of regulating the access of visitors to patients in the small-pox hospitals of the Metropolitan Asylums Board is one requiring much tact and delicacy for its satisfactory solution. The Board has had before it several alternatives—among them (1) to forbid such visits altogether, and (2) to allow only revaccinated persons to enter the hospitals. Obviously the proposal to deprive the dying of the consolation of a last sight of those near and dear to them could not be entertained, nor did the Board see its way to refusing admission to non-vaccinated persons, although strong persuasion is brought to bear on such visitors. The Board has decided that in future the dangerously ill may receive one visitor a day except in respect of the father and mother, who may visit together. Stringent precautions are taken to minimise the risk of infection, and the names and addresses of

all visitors, whether vaccinated or not, are forwarded to the medical officer of health of their districts. Beyond this the Board was not disposed to go, and we think public opinion will on the whole endorse their attitude. In the appendix to a recently issued report, some interesting figures are given concerning the incidence of the disease among the visitors. Of 1,372 visitors to patients during the six months ended February 28th last, 964 were protected by vaccination at the time of the visit, and seven of these contracted small-pox, being .73 per cent.; while of the remaining 408 persons who refused revaccination at the time of the visit, 35 contracted small-pox, or 8.58 per cent. In the light of these figures it is open to question whether the Board would not have been justified in declining to admit non-vaccinated visitors altogether.

Opium or Morphia?

So little instruction is now given in pharmacology to medical students that the majority of them become practitioners without having any clear idea why some physicians in certain cases use alkaloids and in others select crude drugs. This is particularly marked in the case of cinchona and quinine, nux vomica and strychnine, opium and morphia. One of the reasons for selecting an alkaloid is that the dose can be accurately measured; but with standardised solutions and solid extracts the dose can be given with quite as much accuracy. As a rule the student sees the cinchona preparations prescribed in secondary syphilis, and in cases of anæmia; in chronic catarrhs of the stomach and intestine the preparations of nux vomica are preferred to strychnine. When he comes to study the therapeutics of opium he learns from one of our greatest pharmacologists that "in prescribing opium the physician administers a complicated body producing secondary effects which cannot be regulated, depending as they do on the varying proportion of the alkaloids contained in the opium. He should therefore never prescribe it where the conditions are urgent, and where the object is to produce rapidly and decisively the special action which morphia possesses." We have no intention to discuss the wisdom or otherwise of this dogmatic teaching which is in theory generally accepted since 1816 when Sertürner, the then obscure Hanoverian apothecary, discovered the alkaloid. But we do desire to show that the statement is only a partial truth, and that the medical profession in prescribing solutions and extracts of the crude drug with its many alkaloids and bases, has good ground for the practice. It is almost one hundred years since (1803) Charles Derasne discovered narcotine which, not long afterwards, O'Shaughnessy employed with success in the treatment of intermittent fever, and H. S. Roots (1832) recommended as a substitute for quinine to the Indian Government. The alkaloid narcotine produces convulsive action when injected into the lower animals, but the experiments with the substance is not conclusive—it belongs to the codeine or alcohol-radical group, and is a very

unstable base, readily breaking up into cotarnine and opianic acid. We are throughout assuming with Matthiessen and Foster that there is only one kind of narcotine, though there are many homologous bases. Given internally, narcotine has, besides its antiperiodic action, other properties that make it a valuable addition to salts of morphia; it quickens the pulse, raises the temperature, and in full doses acts as a diaphoretic. We are therefore not surprised to find Ebert advocating with much insistence the restoration to opium preparations of the narcotine that is too often removed in their preparation. And as its presence counteracts the depressing effects of the alkaloid morphia, which acts from the first as a depressant, we think physicians show wisdom in prescribing the opium preparations in preference to the alkaloid morphia.

The Use and Abuse of Tobacco.

THAT tobacco smoke had a towering reputation as a deodoriser and disinfectant, long before the invention of bacteriological pathology, is well-known to all who have investigated the history of the subject. The establishment of its character as a preventive of plague infection was effectively rooted in the English literature of the latter half of the seventeenth century. During the terrible epidemic of the plague of London, in 1665-6, the tobacconists' shops were passed over by the Angel of Death. And the recent visitation of cholera to Hamburg gave a corresponding record of the immunity of those privileged establishments against the entrance of that enemy to human life. Of latter years tobacco smoke has, of course, been made the subject of bacteriological experiment, but the results can hardly be said to be so convincingly demonstrative as those which Nature carried out by the much cruder methods to which we have referred. These considerations recall to us the memory of the disinfectant and curative reputation which tobacco-smoke enjoyed at the time of its first introduction to the inhabitants of the British Isles. Students of English literature know something, more or less, of the thundering "Counterblast to Tobacco" which was issued by the British Solomon soon after its adoption by his subjects. In this decidedly emphatic document King James I. informed his readers that "Tobacco being a common herbe, which (though vnder diuers names) growes almost euerywhere, was first found out by some of the barbarous Indians, to be a Preservative or Antidote against the Pocks, a filthy disease, wherunto these barbarous people are (as all men know) very much subiect, what through the vncleanly and adust constitution of their bodies, and what through the intemperate heate of their Climate; so that as from them was first brought into Christendome, that most detestable disease; so from them likewise was brought this vse of Tobacco, as a stinking and vnsauourie Antidote, for so corrupted and execrable a maladie, the stinking suffumigation whereof they yet vse against that disease, making so one canker or venime to eate out another." In this light we have strongly placed before us the value of

tobacco smoke against three of the greatest enemies of the physical welfare of humanity: plague, cholera and syphilis!

Is Leprosy Curable?

THE perusal of M. Dom Santon's great monograph "La Léprose," which appeared about twelve months since, leads us to the conclusion that to-day there is no reason why we should look on all forms of leprosy as incurable. The pessimistic view has too long paralysed medical action and interfered too much with a systematic attack on the disease by our modern methods of treatment. M. Dom Santon is not at all optimistic in his views. He made the circuit of the globe that he might visit every leper colony, and it is interesting to note the conditions under which the victims of the disease live. In not a single leper colony was there an approach to cleanliness, in all the sanitary conditions were disgraceful, and the dietary was poor in quality, and either eaten raw or prepared in the most unappetising manner. The patients themselves appear in the great majority of the cases to be devoid of hope, and in silent despair await the inevitable. Withal, we find that he records that when lepers are removed to a healthy climate, receive proper dietary, and are necessitated to practice personal cleanliness, their conditions so improve, that in periods varying from 2, 5, 10, 15, and 20 years they are practically cured. In some cases a spontaneous cure results, of this type is the interesting series of cases brought before the Alumni Association of the University of California, by Dr. D. W. Montgomery. The disease was contracted in the Hawaiian islands by a missionary, a married man, and father of eight children. His case is, however, open to some doubt, the case occurred so far back as 1837. The sixth and seventh children were twins, and one of them, the seventh child, developed leprosy, and an account of this was published by Dr. Shoemaker. The third, fourth, and seventh children married, the latter twice. Of these the third child, a girl, had six children, of whom the second and third suffered from well-marked anæsthetic leprosy, though an examination of the blood in these cases failed to find any *lepra bacilli*. The third boy developed anæsthetic leprosy also. It is unnecessary to go through the remaining cases, suffice it to say, that of the descendants of the missionary seven had well-marked leprosy, and of these five, still alive, have recovered. One is dead. She suffered from erythematous leproide, which disappeared in about one year during her stay in the lunatic asylum, Honolulu, where she remained afterwards free of the disease until her death twelve years afterwards. The remaining leper of the seven has been lost sight of. The cases not only show that leprosy is an hereditary disease, but they demonstrate that it does not always terminate fatally, and they emphasise what M. Santon teaches that the disease should be grappled with as a curable one, and the first step in the process is the improvement of the hygienic surroundings of the patients. Driving lepers into isolated village communities

intensifies the evil for the leprosy, and by preserving a nidus of infection keeps an ever present danger threatening the health of the public. The isolation sites should be selected with an eye to promoting the recovery of the patients, who should be under the treatment of a medical officer possessing full power as a medical officer of health to enforce cleanliness and to supervise the dietary. The expense would be considerable, but the stamping out of the disease would be an ample recompense.

The Waste Energy of Coughing.

THE amount of energy expended in coughing is very considerable; indeed, one of the patient statisticians for which Germany is renowned has calculated that a patient who coughs once every quarter of an hour for ten hours expends energy equivalent to 250 units of heat, which may be translated as equivalent to the nourishment contained in three eggs or two glasses of milk. In normal respiration the air is expelled from the chest at the rate of four feet per second, whereas in violent coughing it may attain a velocity of 300 feet. This waste of energy is especially important, because it occurs, for the most part, in persons whose assimilative functions are already working under difficulties, consequently the ingestion of the corresponding quantity of nourishment by no means compensates for the exertion. It follows that persistent cough is *per se* a manifest cause of emaciation, though there are many other factors which tend in the same direction, hence the desirability of restraining cough within safe limits, especially when it is due to irritative reflexes such as are excited by laryngitis and pharyngitis. Increased rapidity of expulsion of air without increased exertion is obtained in high altitudes by reason of the low barometric pressure and the consequent diminution of resistance to the exit of the expired air, a fact which explains in part the beneficial influence of high altitudes in diseases associated with cough.

A Scientific Scapegoat.

THE mosquito is surely the scientific scapegoat of the opening years of the twentieth century, and terrible must be the fate that awaits him! A most interesting—and edifying—example of self-denying zeal in this connection has just been reported by Major Buchanan, I.M.S., of the conversion of his senior hospital assistant, Joongey Lal, to the orthodox faith in the true agency in the transmission of malarial disease. This (latter) enthusiastic doubter would not be convinced in any other way than by the practice of the crucial experiment on his own person. Accordingly, he was subjected to the penetrating practice of the properly selected *Anopheles*. He had expressed the wish to begin with inoculation of benign tertian. And his blood was sucked by caged mosquitos in whose circulation the *gametes* of that form of malaria had been shown to prevail. The experiment proved so successful that, although he had previously wished to confirm its results by corre-

sponding tests connected with the pathology of the malignant form of tertian ague, he thought it judicious to change his mind. A correspondingly interesting conclusion—from the historical and theological, if not the scientific standpoint—has been simultaneously arrived at by Dr. Edward Clapton. In his *Life of St. Luke*, recently published, this gentleman has shown evidence that St. Paul's "thorn in the flesh, the messenger of Satan," was no other than the same mischievous malarial mosquito. This is an announcement very similar to that which so much perplexed the orthodox theologians of the nineteenth century—that the "fiery serpent" which troubled the advancing Israelites in the wilderness was no other than the *Guinea-worm* (*Dracunculus Medinensis*). Of such surprises is every scientific edifice constructed!

Poison Labels.

SOME pharmaceutical chemists have commenced to print on their poison labels the antidote for the poison designated on the label. The idea has much to recommend it and may, under certain circumstances, be helpful. There are, however, some objectionable features in the practice. First, the extra-printing takes from the clearness of the label, by necessarily lessening the prominence, the name of the toxic agent and the word "poison." Nothing should be allowed to interfere with or obscure the danger signal. It cannot be too prominent, in clear, bold type—of a size four times that of an ordinary label is what is wanted—a type that will at once catch the eye and arrest the attention; if this is secured an antidote will not be required, and if it is not secured an antidote in lay houses is seldom efficacious. Secondly, the list of antidotes will cause time to be lost in putting them to the test, instead of sending the patient to a hospital, or bringing medical aid to him. Any physician called in to a case of poisoning knows how the danger threatening the patient has seemed to drive away every atom of quiet intelligent thought from his friends, yet it is for them the list of antidotes is printed. Of course there are exceptions; model households where everybody is calm and intelligent, be the danger never so great; but such people will not drink medicine without reading the label, and hence they require no antidote. It is the careless household that suffers, the people who mix up liniments, mixtures, and lotions and swallow their medicines from the bottle without even taking off the wrapper that incur the danger. People for whom the pharmaceutical chemist pastes poison labels on the outer cover and on the front and back of the bottle. When these careless ones, and they are not the minority of those buying medicines, get a liniment or lotion the bottle soon tells of its being used—the cork is either loose or altogether out, and the label is blurred by dirty finger marks and stains of the preparation prescribed. Any well-considered measure for protecting life against accidental poisoning will have our warm support; but we think the suggestion, which some

chemists have carried out, of obscuring the name of the drug and the word poison, with a list of antidotes, admirable as it is in theory, would be in practice pernicious.

The Effect of Inoculation against Typhoid Fever in South Africa.

DR. ALEXANDER CROMBIE has recently published statistics relating to the occurrence of enteric fever amongst 250 officers who came before the Medical Board of the War Office invalided from South Africa on account of wounds and disease. He found that 112, or 44·8 per cent., had been inoculated against enteric fever; that 29, or 11·6 per cent., had had a previous attack of typhoid fever; and that 109, or 43·6 per cent., had not been inoculated or had a previous attack. Of the total number (250) 59, or 23·6 per cent., suffered from enteric fever in South Africa, but of these a considerable number were actually invalided on account of debility following enteric fever, so that this latter percentage cannot be put forward as representing the real proportion of officers so infected. It is, of course, considerably higher than the actual ratio. Of the 112 who were inoculated, 32, or 28·5 per cent., suffered from typhoid fever; of the 29 who had had a previous attack, only 3, or 10·3 per cent., had a second attack in South Africa; and of the 109 not inoculated 24, or 22 per cent., had attacks in South Africa. Of the 112 who were inoculated, 102 had been inoculated once, with 30 cases, or 29·4 per cent.; and 10 with two cases, or 20 per cent., had been inoculated twice. These statistics are, unfortunately, not such as to enhance the value of prophylactic inoculation in the minds of the medical profession.

The Notification of Infectious Diseases.

It is apparently too early to look for improvement in the mental condition of public boards and such like bodies. It is true that education is more general, and that elementary ideas of the importance of prophylactic hygiene have filtered into minds which previously were innocent of such notions, but still there is no evidence that the elected representatives of the public share in this improvement. Presumably, the cause is that what has been gained by the increase of education has been lost by the unlimited powers accorded to illiterate voters. The educated man, no doubt, at present understands the importance of prophylactic hygiene, but then the educated man has but seldom a seat on rural sanitary boards. A striking instance of the amount of crass stupidity which can be exhibited by a popular board has lately been furnished by the action of the Kingstown Urban Council regarding a proposal to adopt the Infectious Diseases Notification Act and Prevention Act. Kingstown is a health resort, and apparently considers that this fact will shield it from the visitation of infection. Consequently, although the importance of notifying infectious diseases has been brought before the Council on many occasions, and although the Local

Government Board Inspector has specially directed the Council's attention to the fact that Kingstown is the only urban district in Dublin in which this Act is not in force, at its last meeting, when the question of adoption of the Act was again brought forward, consideration of the matter was postponed for twelve months. And yet Kingstown was, and perhaps is, termed the premier township of Dublin, and is generally crowded with visitors, and with convalescent invalids. We wonder if the opponents of notification will justify themselves, as did the representative of a neighbouring village in a similar matter, by saying, "the inhabitants are all fishermen, and don't understand such things. If visitors like to come they must take the risk."

An Improved Method of Percussion.

THE simplicity of percussion as a method of physical diagnosis may explain the fact that although it has been in daily use for close upon a century, little or nothing has been done to improve upon the original plan. It is, however, a common experience that, among men similarly trained, some are able to obtain by the method much more precise and trustworthy information than others. This shows that even in such a simple matter there is scope for tact. A common error in attempting percussion is for the hand to be laid flat upon the surface to be examined, instead of placing only the extremity of the anvil finger thereon, an arrangement which has for effect to dull the resonance. An improvement has been suggested by a Hungarian physician, Dr. J. Plesch, which a simple trial will show to merit that description. Instead of placing the hand on the surface in the manner just described, his plan is to flex the middle finger of the left hand *at a right angle*, at the joint between the first and second phalanges, only the pulp of the finger being brought into contact with the surface, by forcibly extending the joint between the second and third phalanges. Percussion is then practised on the lower epiphysis of the first phalanx. This is claimed to give a clearer note of resonance, and to have the advantage of enabling the observer to limit his investigation to a smaller area of the surface. In abdominal percussion, too, this method is less distressing to the patient than when the flat of the hand is applied.

Cancer Research.

It is encouraging to note that the large private fortunes which are becoming comparatively common in many parts of the civilised world are not retained invariably for personal ends. In the United Kingdom, for example, several illustrious examples of gifts to the nation have been recorded during recent years. So far as the progress of preventive medicine is concerned, the princely gift lately given by Sir Edward Cassel, towards the solution of the tuberculosis problem will mark an era in that beneficent campaign. For some time past signs have not been wanting that steps would be taken to organise the resources of modern science in the investigation of

cancer. Last week it was announced that a Dundee manufacturer, Mr. J. K. Caird, had made an offer of £18,000 to establish a cancer hospital in connection with the town infirmary. At the same time he offered to guarantee £1,000 a year for five years for a laboratory in which original research work could be conducted. So far as the terms of this munificent gift are apparent it might be wished, from the purely scientific point of view, that the larger sum had been devoted to research. There is no practical reason why cancer patients should not be treated in the ordinary surgical wards of any properly-equipped hospital. From a purely philanthropic point of view Mr. Caird is entitled to public gratitude for adding to the hospital accommodation of his native town. The case of cancer differs from that of consumption, inasmuch as special hospitals for consumptives isolate so many centres of tuberculous infection from the healthy portion of the community.

Coroners and Nurse Witnesses.

A SOMEWHAT peculiar passage-at-arms is reported to have taken place a few days since between the resident medical officer of the Bootle Hospital and Mr. Coroner Brighouse. It seems that the coroner had summoned a nurse employed at the hospital to give evidence concerning the death of a woman who had died in the institution, ignoring the medical officer, who took advantage of the opportunity afforded by the inquest to intimate to that official that he was in charge and was responsible for anything that took place therein. Of course, the coroner declined to receive mandatory instructions from a mere house surgeon, and said so, and there the matter rests. The right and power of the coroner to summon whom he may please to give evidence is unquestionable, but at the same time it is unusual, not to put it more strongly, for a coroner to appeal for evidence to anyone other than the medical officer in charge. Circumstances might conceivably present themselves in which a deviation from the usual procedure would become necessary, but no such circumstances came to light on the occasion under consideration. We would remind Mr. Samuel Brighouse, County Coroner for South-west Lancashire, that "'Tis good to have a giant's strength, but 'tis not good to use it as a giant."

The London Water Bill.

It is now certain that Mr. Long's Water Bill for the Metropolis will be considerably modified from its original form before it passes into law. As pointed out at the time in the columns of the MEDICAL PRESS AND CIRCULAR, his proposals were open to most serious objections. A Joint Committee of both Houses of Parliament was appointed to consider the transfer of the eight metropolitan water companies to a Water Board. That committee has now reported adversely to some of the most essential features of Mr. Long's scheme. They have decided to cut out the representation of the Borough Councils of the Metropolis, and also of the urban districts and boroughs

of the bordering counties, with the exception of West Ham. The promoters have been requested to draw up a fresh scheme for a Board of about thirty-five members, including chairman and vice-chairman, but without giving a majority to the representatives of any one county. These alterations greatly strengthen the hands of the London County Council in their fight against the monopolist companies. The long and weary struggle that has waged over the water supply of London is a standing object-lesson to every town in the United Kingdom.

Judicial Decision on New Milk.

THE decision of the High Court of Justice in the appeal case of Smithies against Bridge will, we hope, put an end to many of the plausible excuses put forward by milk contractors for supplying an article deficient in fats. In the case that was the subject of the decision the milk supplied contained only 2.09 per cent. of fat, and the explanation offered was that the cows supplying the milk gave it deficient in fat; and the contractor claimed that he was not liable for a prosecution because he supplied the natural product without being tampered with. It was also argued that there was no milk standard. The Lord Chief Justice pointed out that the order of the Board of Agriculture as to the composition of milk does not establish a standard for what is or what is not genuine, but is only *prima facie* evidence, withal the purchaser when he asks for new milk is entitled to get an article that is not other than ordinary new milk by reason of any special way the cows have been treated. If it were otherwise the door would be open to all manner of abuse; a contractor or dairy keeper would be free to give his cows brewers' wash and grain, and thus enormously increase the flow of milk of an inferior quality. Milk enters so largely into the food of children and the dietary of the sick that its purity cannot be too strictly guarded, and we hope we are done with the ingenious excuses of dairymen who keep abnormal cows.

Final Report of the Anderson Fund.

SIR C. C. KNOLLYS, K.C.M.G., Colonial Secretary of Trinidad, in a letter bearing date April 19th, reports the receipt by him of the sum of £258 15s. 6d. subscribed to this fund, and the expenditure of that amount in the purchase and repair of three removable wooden houses in Port of Spain by his instructions on behalf of Mrs. Anderson and her twin sons. In one of these houses she will reside, while from the other two she will draw an annual total net rental of about £50. He expresses his opinion that certainly the money could not have been expended to greater advantage. Mrs. Anderson also writes to convey her sincere thanks to Lord Stamford and his committee for their sympathy shown in the trouble they have taken, and her deep sense of gratitude to subscribers, and to the proprietors and editors of the medical journals for the great help they have given, which has relieved her of intense anxiety as to the future of her sons.

Ludgate Hill as a Health Resort.

IN the second volume of the Report of the Committee of the Royal Medico-Chirurgical Society on the Climates and Baths of Great Britain, reference is made to Dr. Norman Moore's description of Ludgate Hill as an old-time health resort:—"London was, perhaps, once a sanatorium for malarial cases from Essex. St. Earconwald, Bishop of the East Saxons, was buried early in the seventh century in his cathedral of St. Paul. The litter in which he was carried about when too ill to walk or ride was placed there, and a visit to his tomb has cured many sick East Saxons. It is reasonable to suppose that a stay on the healthy upland of Ludgate Hill, while performing devotions at St. Earconwald's tomb, was a natural cure for the tertian fever of the Essex marshes." Dr. Moore explains that Pilgrim Street, leading into Ludgate Hill, was the old way from the landing-place near the mouth of the Fleet, to St. Paul's and to the tomb of St. Earconwald; and adds the interesting personal note:—"When I lived at St. Bartholomew's, I often looked at the name of Pilgrim Street with interest, as the memorial of a time when Ludgate Hill and St. Paul's Churchyard were a health resort, about which anæmic East Saxons might be seen walking, enjoying the dry soil and fresh air, paying their respects to St. Earconwald, and refreshed more and more every day by the breezes from the hills of Hampstead and Highgate." And now we seek our health resorts in distant lands and discard the haunts of our forefathers.

The Bristol Pseudo-Plague Bacillus.

OBJECTION to such anomalous nomenclature might be taken on several grounds. But at present Dr. Klein, the discoverer of this new microbe is content to glorify the ancient port of Bristol by giving the fresh foe the designation of "the Bristol bacillus" for it was in dead rats sent from a ship at Bristol that these plague-like organisms were found. Morphologically they are practically identical with bacillus pestis, but cultural experiments show them to be quite unlike this much-dreaded micro-organism. Dr. Klein at the last meeting of the Pathological Society showed various cultures of "the Bristol bacillus" and clearly indicated the need for care and thorough investigation to prevent confusion between it and the true bacillus of plague. Bacteriologists acting for our port sanitary officials will do well to make a note of Dr. Klein's advice.

The Health of the School Girl.

THE school girl of to-day is, in the natural course of events, destined to become the mother of the near future. Nothing should be allowed to interfere with her fitness to attain to her true physiological destiny. The school and the health of school girls has recently received a good deal of attention on both sides of the Atlantic. It has been objected, not without reason, that the school system fails to recognise individual variations in the child, and especially between the boy and the girl, and thus does not adapt the training to the individual need. The

health of school girls about puberty is often far from perfect. The burden of school work together with the demands of outside life often proves disastrously heavy. Neglect of matters pertaining to school hygiene still continues. The lack of satisfactory vital statistics in relation to the school population is much to be deplored. There can be no doubt that faulty school life goes far to unfit a girl for making the best of college training, and much that at present is inseparable from our educational methods prevents the fullest physical development of the female and hinders her in attaining to the joy and dignity of motherhood.

Electricity and Bacteria.

THE effects of direct, alternating, and Tesla currents on bacteria are of much interest. Zeit finds that a continuous current of 250 to 300 ma. passed through bouillon cultures kills non-resistant bacteria by heat; that 48 ma. used for two or three hours are antiseptic, not germicidal; that non-resistant forms are killed by a current of 100 ma. after an hour and a quarter through the formation of electrolytic products; that anthrax spores are killed in two hours, and spores of bacillus subtilis were alive after three hours. No antiseptic nor bacterial effect resulted from passing Tesla currents around a bacterial suspension within a solenoid. Dr. Foulerton, of the Middlesex Hospital, at the last meeting of the Pathological Society dealt with this question and recorded the results of a series of experiments which went to show that distinct germicidal effects could be obtained by the use of high tension alternating currents. This, however, is in opposition to the conclusion of other observers. A wide field for careful experiment lies open to bacteriologists. At present we must retain an open mind and wait for more conclusive results.

THE Health Committee of Accrington Town Council have resolved that an intimation be given to the members of the medical profession that phthisis will in future be regarded as a notifiable disease.

PERSONAL.

DR. J. E. WOLFHAGEN has been appointed German Consul at Hobart, Tasmania.

DR. WILLIAM S. PLAYFAIR will occupy the chair at the annual dinner of the Indian Medical Service at the Café Monico, on Thursday, June 12th.

DR. WILLIAM HOFFMEISTER, medical attendant to the Royal establishment at Osborne, has been appointed a Member of the Fourth Class of the Royal Victorian Order.

DR. HENRY SHINGLEWOOD TAYLOR, J.P., has been appointed a Commissioner for receiving the oath of allegiance to his Majesty for the district of Ficksburg, O.R.C.

THE Bishop of London is to take the chair at the forty-second annual dinner of King's College, London,

which will be given at the Café Monico on Monday, June 16th.

PROF. RUPERT BOYCE, Professor of Pathology at University College, Liverpool, and Mr. Williams, Bate Hardy Demonstrator in Physiology at Cambridge, are proposed for election into the Royal Society.

THE Victoria Cross was bestowed by the King at Buckingham Palace on Monday last on Captain E. T. Inkeon, M.R.C.S., L.R.C.P. Lond., Royal Army Medical Corps, for distinguished service on the battle field.

THE King has sanctioned the following promotions and appointments to the Order of the Hospital of St. John of Jerusalem in England:—Robert Brudenell Carter, F.R.C.S., to be Knight of Justice; Robert Fraser Calder Leith, M.D., F.R.C.P. Ed., and Sir William Henry Bennett, K.C.V.O., F.R.C.S., to be Knights of Grace.

THE Lord-Lieutenant dined with the President and Fellows of the Royal College of Surgeons of Ireland on Saturday evening, and afterwards delivered an address eulogising the gallantry of Surgeon-Captain Crean, which had gained for him the Victoria Cross. The honorary fellowship of the College was bestowed on Captain Crean during the evening.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE LUNACY QUESTION.

FROM time to time note has been made in the public Press and elsewhere of the constantly growing estimated expenditure on the asylum proposed to be built at Bangour for the pauper lunatics of Edinburgh and district, and at last a special committee have reported to the Board in such a fashion as to throw the whole scheme into the melting-pot once more. For sixty years the pauper lunatics of Edinburgh have been boarded at Morningside Asylum at a cost of £33 per inmate per annum and at Craiglockhart Poorhouse at a cost of £23. Owing to lack of accommodation at Morningside negotiations were entered into which resulted, in 1897, in the formation of a lunacy board for the Edinburgh district, which immediately took steps to acquire a site for an asylum to accommodate 600, and capable of being extended to hold 1,000 inmates. Building plans on a lavish scale were got out, interior fittings of costly design were suggested, and the total cost of the scheme was to reach the extravagant figure of £641,735. The special committee now report that the plans are much more costly than any Lunacy Board should authorise, and consider it essential that a radical re-modelling of elevations and specifications should take place. The total cost of their scheme comes out at £397,003, as compared with the £641,735 of that recommended by the former Lunacy Board. Following on this report, and in continuation of the views expressed by him on the treatment of incipient cases of mental disorder, Dr. Clouston, of the Royal Asylum, comes forward with the proposal that the City Parish Council should establish a hospital near Edinburgh, as a supplementary building to Bangour, for the more acute and curable cases, to which they would be sent for, say, the first three months. A simple, uncomplicated building for 100 beds could be put up for £200 a bed, which would, of course, be deducted from the cost of Bangour. This he would call the "Queen Alexandra Hospital," or some other name which would not imply any evil suggestion to the patients' minds. Dr. Clouston's ideal is to have four means of treating brain diseases in Edinburgh:—1, the Royal Infirmary, for incipient cases; 2, the Queen Alexandra, for the acute; 3, Bangour, for the

more prolonged and the chronic; 4, the "boarding-out system," for the quiet and easily managed. "Pauper lunacy," he justly remarks, "is a misnomer"—five-sixths of the patients have nothing to do with pauperism, except when overtaken by this dire affliction. It may be that the unparalleled delay in the whole business of Bangour Asylum will, after all, prove a blessing if it lead to the District Lunacy Board adapting their buildings and methods to the modern treatment of insanity.

PHYSICAL TRAINING IN SCOTLAND.

Slowly but surely the country is beginning to realise that physical efficiency is a necessary basis for national well-being. It is to be hoped that the work of the Royal Commission on Physical Training in Scottish Schools will furnish material which shall aid to procuring a readier access to the sources of national strength. The Commission is to inquire into the opportunities for physical training now available in the State-aided day schools and other educational institutions of Scotland, and to suggest means by which such training may be made to conduce to the welfare of the pupils. It is also to endeavour to ascertain how such opportunities may be increased, by continuation classes and otherwise, so as to develop, in their practical application to the requirements of life, the faculties of those who have left the day schools. We trust opportunity will be afforded for the presentation of medical evidence, and that the leaders of the profession in Scotland will see to it that such material as is in the hands of medical men shall be forthcoming. We venture to think that in a matter concerning the physical well-being of the community it is the duty of the medical profession to assume its rightful position, and by a scientific presentation of the case affirm our contention that medical men should take their place as leaders and form and mould public opinion, rather than silently acquiesce in the maintenance of obsolete form or willingly follow in the fashionable crowd.

We trust the Royal Commission will lose no time in making known the results of its inquiries, and will suggest means for securing the highest physical development and training of the youth of the nation.

Belfast.

[FROM OUR OWN CORRESPONDENT.]

THE ULSTER MEDICAL SOCIETY.

At the last meeting of this Society, held on the 8th inst., Professor Whittla, the President, in the Chair, Dr. A. B. Mitchell showed (a) a radiogram of a very "oblique fracture of the femur," and patient; (b) three patients operated on for abscess due to "spinal caries." Dr. Lyness showed (a) a case of "double talipes equino-varus" treated by excision of astragalus, and (b) a case of extensive epithelioma of the lower lip treated by excision and plastic operation. Dr. Houston showed a case of "pernicious anæmia" which had been in the Royal Victoria Hospital about nine months ago under Dr. Calwell's care. The patient is now in good health, and Dr. Houston said that the red corpuscles numbered 800,000, and the hæmoglobin was 19 per cent. Dr. John Campbell showed a number of specimens of abdominal tumours, and subsequently read a paper on "The Treatment of Dysmenorrhœa."

Dr. Greenfield (Holywood) read a paper on "Some Forms of Peritonitis and their Treatment," in which he gave a most interesting and entertaining account of the treatment as carried out "by the local knowledgeable man" in a village.

A special committee of the society has been holding frequent sittings during the last few months for the purpose of revising the constitution and rules to adapt them to the new circumstances of next session, when the Medical Institute will be opened and handed over to the Society by Professor Whittla. These new rules, &c., will be submitted to a special general meeting in June. Such rapid progress is being made by the builders that it is quite possible that the new home may be ready for the

Society at its opening meeting in November, though when the foundation stone was laid it was not expected to be ready till next year.

Dr. F. K. Wheeler has signified his wish to resign his post of Surgeon to the Royal Victoria Hospital on account of ill health. As it is understood that his ailment is happily of only a temporary nature, he has been requested by the Board of Management to withhold his resignation and take a few months' leave of absence.

There is naturally much rejoicing among its members at the triumph of the Royal University Graduates' Association's policy in the election of six members of Convocation, the six candidates nominated by that Association having been returned at the head of the poll. In many quarters, however, it is felt that as Galway is already represented by two ex-presidents on the Senate Mr. Anderson might well have waited a little while for a Government nomination, and that it is a matter for sincere regret that Sir William Thomson, who has done such excellent work on the Senate, should be displaced.

[We are not responsible for opinions expressed by our local correspondents.]

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

A NEW ASEPTIC VACCINATOR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As Local Government Board Inspectors invariably find fault with the point of the popular Cooper-Rose instrument, on account of it not being readily cleansed, and there being nothing better in the market, I have

been induced to ask Messrs. Arnold and Sons, London, to carry out my idea of one that would remedy the defect, and this they have done most satisfactorily.

It is the usual pencil shape. One end contains the spat, and the other, on being pulled out and reversed, reveals a small case perforated with five small holes at the end, through which five ordinary tailors' needles can be inserted from the inside of the case, projecting externally $\frac{1}{8}$ ths of an inch, and kept in their position by a cap which screws on and off, thus allowing the needles to be renewed at any time, while also exposing sufficient of the points to allow effectual sterilising by the flame of a spirit lamp. The needles, being removed from time to time, do their work most effectually and so gently that children hardly feel the operation, thus avoiding the heavier and painful pressure that is required when immovable needles get blunted.

It is a great advantage to have the needles so easily removable, one can thus accurately regulate the size of the scarifications by using only two or three needles, and these should be made as recommended by Dr. Renner, and not by twirling as when using the Cooper-Rose instrument.

Being made wholly of metal, all or any part of it can be perfectly sterilised by boiling in an ordinary test tube. Refill needles are contained inside the instrument, which pulls apart in the centre. To arrange new needles in their place, hold the small case up to the light, and, with a pair of forceps they are easily put into the holes; when placed, screw on cap and fix it on

end of instrument. I may say this vaccinator has received the approval of the Local Government Board, and I invariably find that the use of it removes one of the great dreads mothers have to vaccination—the ordinary lancet usually being a perfect terror to them.

I am, Sir, yours truly,
J. WILSON, M.D. Ed.
Public Vaccinator, No. 4 District.

Cheltenham.

TEMPERANCE AND ADVERTISEMENT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would be interesting to know what evidence Professor Folet can adduce in support of his statement given on academic authority "that out of every 100 consumptive patients in the Paris Hospitals in no less than 71 per cent. the malady can be traced to alcohol."

It must be evident to any ordinary observer that disease (applying the term in its broadest sense) is a powerful incentive to stimulants, and hence we find that phisical patients among others resort to these; the disease, however, being the cause rather than the effect of the intemperance; and thus we see in the enthusiasm of the total abstinence party they mistake cause for effect.

If the question of total abstinence is solely based on wild speculation, there is more reason to show on presumptive evidence (alcohol being an antiseptic and the blood being charged therewith) that it would rather tend to arrest than to cause the disease, alcohol being inhibitory to the action of the bacillus.

I am, Sir, yours truly,
CLEMENT H. SEERS.

Queen's Road, Peckham, S.E.

STREET MUSIC AND SEASIDE INVALIDS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been called to the article in your issue of the 23rd ult. under this heading, in which the writer, referring to St. Leonards, suggests that "healing and most invaluable therapeutic conditions" can to a great extent be secured "by prudent byelaws, excluding the whole race of roving musicians from the neighbourhood," and makes mention of a medical correspondent who writes "telling of two patients who were disturbed daily by the sudden discordant outburst of a piano organ."

The article would certainly convey the impression that no steps have been taken by the local authority to provide for such a case. On the contrary, they procured an enactment in a local Act, passed in 1885, which gives any householder full power, either personally, or by his servant, or by any constable, to require any street musician or singer to depart from the neighbourhood of the house of such householder, and renders any person who sounds or plays upon any musical instrument, or sings in any street near, or within hearing of such house, after being so required to depart, liable to a penalty of 40s.

The remedy is, therefore, entirely in the hands of householders. If they will not take the trouble for their own convenience and comfort, or that of their visitors, to put the law in motion, the Authority is certainly not responsible. If I am correctly informed, no larger powers exist, so far as the public authorities are concerned, in the metropolis, or in any other seaside or health resort.

The regulations in force at Bexhill are made by a private estate owner, and are, of course, limited in application to that estate. The writer of the article does not seem to be aware that all byelaws made by local authorities have to be sanctioned either by the Home Secretary or the Local Government Board, as the case may be; and I have no hesitation in saying that, in my opinion, a bye-law for "excluding the whole race of roving musicians" from any neighbourhood would not be allowed, but even if it were so, would be held by the Courts to be unreasonable and bad.

I am, Sir, yours truly,
FRED A. LANGHAM, Mayor.

Mayor's Parlour, Hastings, May 8th, 1902.

NATALITY IN GREAT BRITAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a recent debate in the House of Lords on temperance legislation the Prime Minister reproached a certain right reverend prelate with having mixed up two very distinct objects, viz, the prevention of drunkenness and the prevention of drinking. *Mutatis mutandum* your correspondents, or some of them, appear to confuse the prevention of families with the limitation of families. The former merits unstinted condemnation as anti-social and selfish; the other will be conceded by all reasonable persons to be not only permissible but highly commendable.

After all, the "man in the street" must not arrogate to himself the right to dictate to his neighbour the number of children he ought to add to the population; still less is he entitled to impose his fastidiousness concerning the methods employed to attain the object in view, assuming, of course, that no extra-legal measures are contemplated.

Healthily constituted couples, not hard pressed for the means of existence, who deliberately and wantonly eschew a family, really call more for pity than blame. Such practical egotism, as "Gynæcologist" very aptly observes, is demoralising to those who practise it, and brings its own Nemesis. The very worries incidental to the possession of a family have their salutary aspect, for, as an American novelist sentimentally observes, "it's a good thing for a dog to have a certain number of fleas, because it prevents him worrying himself over the fact that he is a dog." Life would be insipid were it not for its trials, and unalloyed pleasure, were it humanly possible, would promptly cloy the palate.

The moral of it all is that selfishness, in this anti-social or any other form, is fraught with disaster to its votaries, while the abnegation, of which the rearing of a family is the outward and visible manifestation, brings its own reward and satisfaction.

I am, Sir, &c.,
AN OLD BACHELOR.

HOSPITAL OF ST. FRANCIS.—AN ANTI-VACCINATIONIST HOSPITAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to an editorial appearing in your issue of the 9th ult., we desire to point out that the letter from the Secretary to the Hospital of St. Francis in the number dated April 23rd disclaims, on the part both of the Council and their staff, their approval of the remarks made at the annual meeting by the chairman of that meeting, who neither is, nor has been, chairman or member of the Council.

To make our position plain we wish to state that no member of the medical staff is either a vegetarian, anti-vaccinator, or anti-vivisectionist, though by the rules of the hospital no medical man who practises vivisection is eligible to work in connection with it.

We are, Sir, yours truly,
F. INGOR WILLEY. A. E. GILES.
J. W. MACVINE. M. AGAR.
W. G. HALSTEAD. T. J. HITCHENS.
F. J. FIELDER. B. STEVENSON.

New Kent Road, S.E., May 2nd, 1902.

[We have pleasure in publishing this disclaimer, which places matters on a more satisfactory footing. We trust that steps will be taken to protect the institution against irresponsible statements on all future occasions.—Ed.]

DR. SHAW MACKENZIE AND THE SAMARITAN HOSPITAL.

We have been asked to publish the following letter:—

[COPY.]

Samaritan Free Hospital for Women and Children, Marylebone Road, N.W.,
April 16th, 1902.

DEAR SIR,—The Committee of Management of the Samaritan Free Hospital understand that some mis-

apprehension has arisen as to the circumstances attending your provisional appointment as honorary physician to the hospital and the subsequent election of another candidate.

The Committee willingly state that your non-election permanently was not attributable to any fault or shortcoming on your part. You gave your valuable services to the hospital for some weeks, and the Committee had no reason whatever for dissatisfaction.

The Committee take this opportunity of expressing their regret that the letter to you, and the communication to the "Medical Directory," notifying your appointment, omitted to state that it was provisional only.

I am, dear Sir, yours faithfully,

W. GUNTRIP KING, Secretary.

To J. A. Shaw-Mackenzie, Esq., M.D., &c.,
31, Grosvenor Street, W.

New Inventions.

THE QUADRANT MOTOR BICYCLE.

WE were asked by a correspondent last week for our opinion of motor bicycles for country practice, and of the most serviceable form. There can be no doubt that a trustworthy, safe, and easily worked motor bicycle offers to a country practitioner—especially to one who lives in a district where the distances to be travelled are considerable—very obvious advantages. Accordingly, every advance which takes the motor bicycle a little further from the stage at which it was only a glorified toy, and a little nearer to a working machine of practical use, will be eagerly welcomed by many medical men. We have recently had placed at our disposal by the Dublin agency of the Quadrant Company, Townsend Street, an improved Quadrant motor bicycle, with permission to expose it to any fair tests which would elicit its speed, hill-climbing capacity, and simplicity of working. We may say at once that we were thoroughly satisfied with the manner in which the bicycle did its work. It went of its own accord at a rate of some eight to ten miles an hour up hills which we confess we find a difficulty in riding on a safety, while, when helped a little by pedalling, it went up extremely steep gradients. On level ground, a speed of from fifteen to twenty miles an hour was easily obtained. The mechanism of the bicycle appears to be simple, and unlikely to go out of order if it receives fair treatment. Any slight breakdowns can be easily repaired by any one who has the slightest mechanical skill. The Quadrant possesses the great advantage over, we believe, all other motor bicycles, that it is controlled by a single lever, and that consequently the ease with which it is managed is very greatly increased. The brakes are good, and enable the bicycle to be ridden safely down almost any hill. The tank contains sufficient petrol for about 100 miles, while the accumulator, from which the current for the ignition spark is obtained, will last for 700 miles, and is then readily recharged. For country use, however, an accumulator possesses the drawback that it may be difficult or impossible to get it recharged when required. If a trustworthy dry cell of sufficient power could be substituted the advantage would be considerable. However, for town use the accumulator is perfect. The engine used is of the well-known Minerva type. We fancy, that, before long, many medical men in the country will have substituted some form of motor vehicle for horses and carriage, and, for those who do not wish to incur the cost of a motor carriage, a motor bicycle will be most suitable. Indeed, with the object of acquiring experience and skill in handling a motor, we would suggest to any one who purposes purchasing a car, to first obtain a motor bicycle and to learn from it the peculiarities of motors.

The Age of Medical Students.

A new bye-law, regulating the admission of medical students to Aberdeen University, has come into force, according to which no student will be admitted under the age of 16 years. A certificate of birth will in future have to be produced by applicants for registration.

Literature.

DISEASES OF THE RECTUM. (a)

WHEN a book has reached its seventh edition it may fairly be regarded as having been a success, and we think we can say with truth that the work before us is another worthy descendant of the original volume by Mr. W. Allingham brought before the medical profession a good many years ago. The main differences, as Mr. Herbert Allingham says in his preface, in the seventh edition will be found to deal with the subjects of excision of the rectum and inguinal colotomy. With regard to the former, we notice that a decided preference has been given to Kraske's operation, which is here mentioned first, the authors say: "In former years the rectum was always excised by the perineal method. Kraske's method . . . is a great improvement on this, so that his method, or some modification of it, should be always used. The only exception to this rule is in cases when the growth is at the anus or limited to the neighbourhood of the sphincters." Whereas, in the sixth edition, in speaking of perineal excision, this being here mentioned first among operations for excision of the rectum, we read: "By the following method (perineal excision) the rectum is most easily and rapidly excised"; while the description of Kraske's operation is prefaced by the phrase: "A modification of excision of the rectum, which has been freely discussed of late years, which has found favour with some surgeons, is Kraske's." From these extracts it may be concluded that the large experience of Mr. Herbert Allingham between 1896 and 1901 has led him to prefer Kraske's operation to any other for all cases with the one exception he mentions. Turning now to the operation for inguinal colotomy, we find several practical and very important modifications in the technique: in the 1896 edition the authors direct the first incision of the operation to be made about an inch and a-half (3.8 cm.) inside the left anterior superior spine, but in the present work the position for this incision is indicated as the junction of the middle and outer thirds of a line from the umbilicus to the anterior superior spine; in the 1896 edition we were told "With a stroke of the knife the external oblique and the other muscles are severed"; in the 1901 book we are taught to tease through the rest of the abdominal muscle with the fingers, after division of the fibrous aponeurosis of the external oblique. No special precaution before opening the peritoneum is given in the 1896 edition, but in the present one we are cautioned to take the picked-up portion between the fingers to make sure there is no gut also picked up with it. Other most important changes in the operation are: doing away with the flat sponge, not sewing the parietal peritoneum to the skin edge, which has been found to be not only unnecessary but even dangerous, a conclusion based on the experiments of the late Mr. Greig Smith. One of the most important modifications in the present work is certainly the employment of a Spencer Wells' clip passed through the mesentery to support the intestine in lieu of a stitch, owing to the latter, it is pointed out, not being always safe, as it may cut through, and if this happens in the early days of the colotomy the intestine will fall back. Again, Mr. Allingham opens the gut now by a transverse incision instead of one from above downwards. It is interesting to read the changes in an operation in five years, changes which have been dictated by experience, and it is refreshing to find a surgeon frankly discarding his pet methods the instant he finds a change of technique to be of advantage to the patient. Space will not allow our alluding to many other points of interest in this edition, which, by the way, has been condensed from 476 pages to 464 without the omission of any important matter. The illustrations are well up to the mark of the text; in fact, the work will amply repay perusal.

(a) "The Diagnosis and Treatment of Diseases of the Rectum." By William Allingham, F.R.C.S. and Herbert W. Allingham, F.R.C.S. Seventh Edition. Pp. 464. London: Baillière, Tindall, and Cox.

PHARMACOPEDIA. (a)

THE art of imparting instruction or conveying information about drugs may fitly be termed "pharmacopedy," and the intention of the authors of this book is, therefore, exactly expressed by the title of the work, the name, "Pharmacopedia," meaning simply instruction or information about drugs. This instruction takes the form of a commentary, and is confined to the drugs of the Pharmacopœia. The arrangement is alphabetical, and there is also a good index, so that the student has no difficulty in finding any subject to which he may desire to refer.

In describing the drugs and medicinal preparations the order of the Pharmacopœia is followed and the account of each drug ends with a commentary. Of these commentaries we cannot speak too highly. They are the outcome of a fulness of knowledge and of a practical experience that is apparent in one and all of them. Any one drug treated of might be taken as showing the thorough grasp and intimate knowledge of their subject that the authors have. But we desired to see how the great and important group of the *toluol benzol* series was treated and turned to *acidum benzoicum*, which occupies two pages and a-half, and we could not suppress our admiration for the mastery of the subject that enabled the authors to condense so much information into the space, and yet to make a clear, intelligible statement on one of the most interesting drugs in the Pharmacopœia.

As a further example of a terse, lucid description of a drug we would quote the account given of *cannabis indica*; it is very brief, yet nothing of importance is left out, and all the essentials of O'Shaughnessy's classic account are embodied, as well as Donovan's researches.

We would also draw attention to the article on *Chloroform*, the commentary on which should be printed in large type and hung up in every operating theatre in the country.

A special article is devoted to each of the Galenical preparations, after the manner of Brand's and A. T. Thomson's works, that on extracts occupies eleven pages, and embodies all our existing knowledge on the subject. It is intended almost exclusively for pharmaceutical students and chemists; nevertheless, it may be read with benefit by medical practitioners who desire to select their therapeutic remedies with a knowledge of the relative values of the different preparations.

Of the forty-six full page plates we cannot speak too highly; they are beautifully executed and very true to nature—they cannot fail of being helpful to both chemist and student.

We hope that in future editions the authors will be induced to include a greater number of drugs, and we would suggest the advisability of giving the synonyms as well as the official names of drugs and preparations.

To the physician the book would be greatly enhanced in value if the authors had given a short account of the physiological action and therapeutic uses of the different medicinal agents.

The authors have done their work with a thoroughness and a knowledge of the subject that is creditable to British pharmacy and is highly praiseworthy.

WALSH ON DISEASES OF THE HAIR. (b)

THIS book, No. VI. of the Medical Monograph Series, well maintains the level of excellence reached by former volumes. It is a well-chosen subject, and contains all that medical men need know about the treatment of the hair and its diseases. Dr. Walsh is master of a terse and clear style, and in this little book has treated his subject with evident interest and information. As he himself is careful to point out, there yet remains a great deal to be learned about the pathology and treatment of many maladies that affect the human hair. At the same time it

may be said that he has brought together all that is known scientifically about the matter, and has added the result of a large personal experience of his own. Indeed, we know of no other book in the English language dealing with the diseases of the hair from the pen of a really scientific and well-informed writer. The subject is one that deeply affects almost every person living at one period or another of his lifetime. Greyness and baldness, according to the author, are for the most part preventible conditions, due to the symptomatic chronic inflammatory disease known as *seborrhœa*. This trouble may originate in the cradle or at any period onwards, and if taken in its early stages may be arrested at almost any stage by appropriate treatment. The infectiveness of *seborrhœa* clearly involves the infectiveness of its results, greyness, thin hair, and baldness. It also involves the necessity of preventive treatment by disinfection of combs and brushes and of the implements in use at the barber's shop. All these points are fully dealt with in Dr. Walsh's able and exhaustive monograph. The subjects of ringworm of the scalp, ringworm of the beard and body, alopecia areata, and other disfiguring and often rebellious affections of the hair are clearly described. Speaking of electrolysis for superfluous hairs, the author points out that the little operation in question should never have been allowed to drift into the hands of unqualified persons. It is in the power of practitioners in the future to send their patients to medical men, of whom there are always several competent to perform that special treatment. There is no particular reason why, armed with the information obtainable from Dr. Walsh's book, the general practitioner should not be able to undertake the treatment of many diseases of the hair. This little volume is certain to add to the popularity of the series of medical monographs of which it forms the sixth. It distinctly fills a gap in medical literature, and as a handy, practical little handbook we venture to predict for it a wide and lasting success. Like all the preceding volumes of this handy little series, it has been produced in excellent style by the publishers.

STUDIES IN HETEROGENESIS (a).

THIS is the first instalment of a new monograph dealing with problems which engaged the author's attention in an earlier work. Heterogenesis, contrasted with homogenesis, or normal development, is the term used for the process by which alien forms of life arise in pre-existing organisms. Very justly Professor Bastian recognises in his introduction the pertinence of the alternative explanations of the appearances he describes as due to polymorphism or infection, and the whole paper, illustrated by a wealth of beautiful photomicrographs, is an attempt to establish the thesis that in the changes described these processes can be excluded. How far he has succeeded, and in what points the proof is inadequate, we will now endeavour to show.

The first chapter deals with origin of the *amœbæ*, monads, and other lowly organisms belonging to the animal kingdom from the protoplasm of the cells of certain algae. The boldness and revolutionary import of such a contention necessitates the most careful scrutiny of the evidence by which it is supported. The vegetative form of one of the *confervæ* was kept in unsuitable conditions and at the end of a week many of the cells become decolourised, break up into a varying number of segments, which after a time show *amœboid* movement. These having been gratuitously assigned to the animal kingdom as ordinary *amœbæ*, their subsequent fate ceases to interest the author, and he directs his energies to excluding the possibility of infection, i.e., the entrance of small *amœbæ* into the moribund algal cells.

The mere fact that so accomplished an algologist as Dr. Cook could not identify the species or genus even of the alga concerned, should have impressed the possibility of polymorphism as a possible explanation is somewhat curious. *Amœboid* movement is not unknown in the

(b) "The Hair and its Diseases." By David Walsh, M.D., Edin., Hon. Physician, Western Skin Hospital, London. W. Medical Monograph Series, No. VI. London: Baillière, Tindall, and Cox. Price 2s. 6d. net.

(a) "Studies in Heterogenesis." By H. Charlton Bastian, M.D., with 210 illustrations from photomicrographs. London: Williams and Norgate. Price 7s. 6d.

plant kingdom, and many cells in the higher plants, and stages in the development of the lower, are devoid of chlorophyll. There can be no doubt that the author was on the verge of a most interesting, and it may be important, find, but the changes in the alga and the fate of the amoeboid derivatives, when transferred to more suitable conditions than occur under a cover glass, must be investigated by modern methods and more continuous observation.

The second chapter deals with the origin of presumptive amoebæ, peranemata, and monads, from encysted ciliates infusorians. We say presumptive, because the evidence that the organisms in question belong to those in general, by having the same life history and mode of reproduction, is wanting. When one considers the complicated processes of conjugation described by Maupas and Hertwig, as occurring in the ciliata, processes only elucidated after months of continuous observation of healthy organisms, and confirmed by all subsequent workers, the observations detailed in this chapter present an unsatisfactory incompleteness, strangely out of keeping with the sweeping conclusions they are made to substantiate. The observations are good and most suggestive, and will well repay investigation, but it must be by the methods by which so much has been already achieved. In not one of the instances is an attempt made to show what becomes of the smaller, more resistive, or more adaptive organism when it is returned to conditions resembling those in which the parent lived and flourished.

The transformation of the eggs of various rotifers into peranemata, monads, and amoebæ, which is discussed in the third chapter, must be placed in a totally different category to the preceding. In the former, polymorphism is seen to be the more feasible and likely explanation; here the nature of the changes suggests infection, and our criticism must be directed to determine what precautions were adopted to exclude that possibility. In the first place, the ordinary methods made familiar by bacteriology could not be put in practice, but the conditions under which these experiments were conducted make one groan in these days of aseptic surgery. Scum from a pond, scrapings of mud, tap water kept in the open air for a time without a cover, and covered with a glass plate when brought into a room at higher temperature, and examined once a day, or even only once a week, for weeks at a stretch. When one considers the rate at which low forms of plant and animal life flourish in animal matter, whether dead or of depressed vitality, in such conditions the "sudden" appearance of amoebæ and flagellate forms ceases to be a mystery.

The general conclusions need not concern us here as they premise the acceptance of heterogenesis. The whole trend of modern work is against this, and it gives the impression of being the easy way out of difficulties, which, had it been made a guiding principle, we should still be ignorant of the complicated life histories revealed by malaria and coccidiosis.

STRUMPELL'S TEXT-BOOK OF MEDICINE. (a)

SINCE the publication of the second English edition of this text-book of medicine seven new editions have appeared in the original German, and consequently many alterations have been made to bring it into line with the most recent views on medical science. As the author points out, it is every day becoming more and more difficult for any one man "to maintain that universal and complete command of facts and theories which is essential for a presentation of the subject which shall be at once brief and true to the present standpoint of science." Though this statement is undoubtedly true, still we believe that for the production of a text-book which will really be of use to the student, that one man must be found. The larger books, which are really collections of monographs on the various subjects by different writers, may be of more use to the qualified

man for consultation and reference, but the student will always turn in preference to the text-book which presents the views of a single author.

The object of the author in this edition is, as he says, to present the essentials of our present knowledge and views of disease by bringing the facts of clinical experience into the closest possible relation with the data of pathological anatomy and general pathology. This is a matter of the first importance in a book designed for the use of students the object of which should be to assist them in interpreting the facts which they observe clinically and suggesting to their minds points for further observation. It is because the book succeeds so well in doing this that we unhesitatingly recommend its use to the student, and believe that it will enable him to travel the thorny path towards his final examinations with more comfort and profit than many of its more pretentious compeers. The section dealing with the diseases of the heart appears particularly well done, and it is here perhaps more than anywhere else that the value of associating and interpreting the clinical phenomena by the facts of pathology is most obvious and instructive. It is, we think, a pity that there is no section in the book dealing with the subject of skin disease, which in this country at all events is always looked on as part of medicine. Such exclusion, however, enables the author to keep the book within much more manageable limits as regards size, and that too without sacrificing any of the space devoted to the more purely medical subjects. The translators have done their work well, and have produced a clear and literary rendering of the original work, while their notes, added in brackets, are always to the point.

THE IMPERIAL HEALTH MANUAL (a).

THE official health manual of a nation like the Germans, who have done so much both by individual and collective effort to further the cause of sanitary reform, cannot fail to be of interest to all desirous of gaining an insight into the rudiments of preventive medicine. To such we can with confidence commend the book translated and edited by Dr. Roche, whose object will be fully attained if he succeeds in arousing a desire on the part of the public to master the ordinary problems of hygiene. A variety of subjects, including water, air, food, and infectious diseases, are dealt with in a concise and lucid manner, while the chapters on anatomy, social relations of man, and the more common accidents leave little to be desired when we consider the class of person for whose benefit the book is intended. The one deficiency in the work which perhaps we may mention is the very limited information given respecting the modes of removal of excreta from the dwellings, and the almost entire omission of any description of the sanitary appliances necessary for such removal. Taken as a whole the little work is admirably suited for a popular treatise on this important subject.

A SYNOPSIS OF SURGERY. (b)

THERE is much in this little book to commend it to students. Originally merely a synopsis of the author's lectures, the "scrappiness" inherent to such compilations has to a great extent been obviated, although from the nature of things a synopsis can never be anything but a synopsis. This being so we are disposed to question the opportuneness of introducing notes of cases, instead of "synopsising" the lessons to be learned therefrom. This plan may, however, be the outcome of the author's views on the desirability of substituting systematised clinical teaching for purely theoretical lectures, although a narrative of observed facts hardly deserves to be described as "theoretical." The plan of the book is good, and if properly worked out we have little doubt that it would command a certain popularity with the class of

(a) "A Text-book of Medicine for Students and Practitioners." By Dr. Adolph Strumpell, Professor and Director of the Medical Clinic at the University of Erlangen. Third American edition translated by permission from the German by Herman F. Viceroy, M.D., and Philip C. Knapp, M.D., with editorial notes by Frederick C. Shattuck, M.D. London: H. K. Lewis. Price 24s. net.

(a) "The Imperial Health Manual." By Anthony Roche, M.B.C.P.I., &c. Second edition. Pages xv, and 301. London: Baillière, Tindall and Cox. 1902. Price 3s. 6d.

(b) "A Synopsis of Surgery." By E. F. Tobin, F.R.C.S.I., Surgeon to St. Vincent's Hospital, Dublin, &c., &c. Second Edition. Price 6s. 6d. London: J. and A. Churchill. Dublin: Fannin and Co.

readers for whom it is intended. But at present it has not been properly worked out, and is in many respects behind the times. To mention only one instance, actinomycosis is described as a tumour most commonly met with in connection with the lower jaw, a statement which, if true of the disease in animals, is hardly as correct in regard to man. Moreover, under treatment, we are told "that of tubercle," no mention being made of iodide of potassium, a drug which in many cases yielded results little short of marvellous. We are fain to add that we have never seen worse printing, many pages being quite illegible, or more careless proof-reading, errors of spelling being indecently numerous. The work is interleaved, and this will enable readers to supply, should space allow, the information which is lacking.

LLANDUDNO AS A HEALTH RESORT. (a)

ANYONE contemplating a holiday in Wales who may have the good fortune to come across this elegantly got-up little book would, we feel sure, start off for Llandudno. The photos, by Mr. A. H. Hughes, are beautifully executed and most attractive. A nervous invalid may not like the look of the crowd seen in the "Happy Valley and Great Orme," but if he turns over the page he will feel relieved as he contemplates the "Lighthouse and Marine Drive."

Brief accounts are given of the working of the drainage system and water supply of the town—works carried out regardless of cost and with most satisfactory results. Immunity from zymotic disease is in a great measure secured by the maintenance of a fully prepared Isolation Hospital. In this, many watering places might take a useful lesson from Llandudno. Vital statistics and tables of temperature are, of course, introduced. It is well this should be; though average and mean temperatures are always very doubtful guides.

That the air of Llandudno is pure and bracing, and very beneficial to nearly every class of invalid is a matter that few who have had experience of it are likely to dispute.

Medical News.

The Late John Bellows.

JOHN BELLOWES, the Quaker archæologist, friend of peace and letters, has just passed away. His portrait in the Academy is striking evidence of our loss. Many medical men will remember the charm of his personality when last summer at Gloucester, during the Cheltenham meetings of the British Medical Association, he took a large party around the old cathedral city and explained its glories gleaned from the fading past. Some of our readers will, no doubt, have used Mr. Bellows' remarkable but in many ways most useful French dictionary.

Royal College of Surgeons of England.

AN election of professors and lecturers will shortly take place by the Council of the College, who will elect the Hunterian Professors, the Erasmus Wilson Lecturer, and the Arris and Gale Lecturer for the ensuing year. Fellows and Members of the College desirous of becoming candidates for these offices should make written application to the secretary, Mr. S. Forrest Cowell, stating the subject upon which they propose to lecture, on or before Monday, June 2nd.

Royal College of Surgeons, Ireland.

THE following Examiners were elected at the meeting of the President and Council last week:—In Anatomy—Ambrose Birmingham, Alexander Fraser. In Surgery—Election postponed. In Physiology and Histology—E. L'E. Ledwich and C. Coppinger. In Ophthalmology—Arthur H. Benson and P. W. Maxwell. In Pathology and Bacteriology—Arthur Hamilton White. In Pathology—R. Allen. In Midwifery and Gynaecology—

(a) "Official Guide to Llandudno and District." By Alec. G. Moy, M.J.I. Issued by the Llandudno Town Improvements Association. Manchester: Henry Blacklock and Co., Limited.

Frederick W. Kidd. In Biology—John J. Burgess. In Sanitary Law and Vital Statistics—H. Benson Goulding. In Engineering and Architecture—J. Charles Wilmot. In Dental Surgery and Pathology—Daniel Corbett, jun., W. G. Story. In Mechanical Dentistry—George M. P. Murray, William Booth Pearsall. In Chemistry and Physics—Edward Lapper, R. J. Montgomery. In Languages—L. J. Woodroffe. In Mathematics, Physics, Dictation and English Essay—J. W. Tristram.

Dublin Death-rate.

THE deaths registered, in the Dublin Registration Area, for the week ending Saturday, May 3rd, 1902, represent an annual rate of mortality of 26.3 in every 1,000 of the population. During the 18 weeks ending with Saturday, April 26th, the death-rate averaged 26.7. There were 22 deaths from diseases of the nervous system; 27 from diseases of the heart and blood-vessels; 32 from diseases of the respiratory system. In 8 instances the cause of death was "uncertified," there having been no medical attendant during the last illness. Forty-three infants, of whom 21 were under 1 year of age, died during the week. In the city proper the death-rate in the following districts was as follows: Summer Hill District, 26.6; South Earl Street, 26.3; Castle Street, 39.6; South City Extension, 42.9.

A Medical Exhibition.

THE sixth annual Medical, Surgical and Hygienic Exhibition will be held in the Queen's Hall, London, on May 20th, 21st, 22nd and 23rd, from 1 p.m. to 10 p.m. A concert by select orchestra will be rendered each afternoon from 3 to 6, and in the evening from 7 to 10. Many novelties will be shown of interest to the profession.

The Guardians' Revenge.

THE Poole Board of Guardians, incensed, it appears, at having had to pay a bill of £180 for revaccination has resolved to take the decidedly novel step of publishing in their next half-yearly account a complete list of the names of those who have thus "pauperised themselves and burdened the rates," doubtless *pour encourager les autres*. Exemption may be purchased by reimbursing the fees. This is a risky attempt at a mild sort of blackmail, and it is possible the auditors may surcharge the guardians with the cost of this wholly unauthorised proceeding.

Deaths under Chloroform.

AN inquest was held last week on a young man who succumbed to chloroform narcosis at the Central Throat and Ear Hospital, Gray's Inn Road, and a verdict of "death from misadventure" was returned. An inquest was held on the 8th inst. on the body of a young married woman who died at the Wallasey Cottage Hospital, while undergoing an operation on the foot. The usual verdict was returned. In neither case are any details forthcoming concerning the mode of administration or the quantity of the drug used.

The Case of Dr. W. T. Law.

THE movement which is on foot to raise a fund for the purpose of indemnifying Dr. W. T. Law in respect of the legal expenses attending the defence of the unsuccessful action recently brought against him by a nurse is making good progress, upwards of £300 having already been promised. The expenses in question, we are given to understand, amounted to about £700.

Conjoint Board in Ireland.

THE following candidates have passed the Final Examination by the Royal College of Physicians and Royal College of Surgeons:—

Four Years' Course.—a. All subjects: John James Bell, Conway Cartright, Thomas Raymond de Castillo. b. Completing Examination; R. E. M. Harvey, C. J. D. Odevaine.

Five Years' Course.—a. Honours: Cornelius Foley. b. All Subjects: H. L. Becker, J. I. Harty. c. Completing Examination: R. Allison, C. H. Browne, S. Browne, H. T. Cookman, C. Waters.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

THE LATE BRET HARTE AND HIS WORKS.

MR. FRANCIS BRET HARTE has just died from malignant disease of the throat. He was in his 63rd year, and with his passing we lose another of those brilliant and versatile Americans we have long since taken to ourselves as friends and almost fellow-countrymen. Bret Harte's delightful books have done much to lighten the day's burden of many an overworked medical practitioner, and have brought fresh strength and courage to many a pain-racked patient. The sufferings of sufferers have been lightened by Bret Harte's humour and raciness, and 'tis sad to think that he, too, in his turn, should have to be taken through the dark valley by malignant disease.

M.D. (GLASGOW).—Braithwaite's "Retrospect of Medicine" ceased to appear last year. We much regret the disappearance of such an old and valued *resume*, but this appeared to be inevitable in "the times in which we live."

DOCTOR'S ORDERS.

THE village doctor meeting a prominent member of the Nonconformist Church, who boasted of his teetotalism, resolved to put him to the test, so he asked him into the hotel and ordered two glasses of wine. After they had drunk them, and two or three more at the doctor's expense, the doctor, thinking he had him, asked: "How does this square with your teetotal pretensions, John?" "Well," answered John, with a quiet smile, "you see, the doctor ordered this"—*Pick-me-up*.

AN INTENDING CANDIDATE.—The next examination of candidates for the Army Medical Service is fixed for July 21st and following days. Applications to compete must be lodged before July 3rd.

MEAT-JUICE AND MARKING INK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the above heading in your last issue some common-sense remarks are made as to the obvious carelessness of allowing poisonous fluids to be placed in bottles bearing the labels of their original contents and left convenient for chance administration to a patient. Marking ink given in place of meat-juice would naturally "play the deuce," and by making extremes "meet" would "mark the close" of a useful life, without the unfortunate patient having even an "inkling of the reason."

I am, Sir, yours truly,

STILO.

MR. WESLEY WILSON.—Your letter with enclosure have been forwarded to the Editor in your division.

HOME WANTED.

A CORRESPONDENT asks if any reader knows of a home in which a patient (gentleman), aged 76, could be received. He is capable of going about and doing for himself, and has no vicious or dirty habits, a simple case of gradual senile decay. Friends could only afford from 21s. to 25s. a week. We will forward any replies that may be sent to our London office.

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, MAY 14TH.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

UNIVERSITY OF LONDON PHYSIOLOGICAL LABORATORIES (South Kensington).—5 p.m. Dr. Leonard Hill: The Physiology of Respiration.

FRIDAY, MAY 16TH.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (North-Eastern Hospital for Children, Hackney Road, N.E.).—5.30 p.m. Cases and specimens by Dr. James Taylor, Mr. Douglas Drew, Dr. J. P. Parkinson, Mr. H. Curre-Smith, Mr. A. B. Roxburgh, Dr. J. H. Squeira, Mr. S. F. Rose, and Mr. Sydney Stephenson. Paper by Dr. C. Hawthorne: A Note on a case of Arthritis accompanying Ophthalmia Neonatorum.

POST-GRADUATE COURSES AND LECTURES (Medical Graduates' College and Polyclinic, 22, Chancery Street, W.C.).—Demonstrations will be given at 4 p.m. as follows:—Monday, Skin; Tuesday, Medical; Wednesday, Surgical; Thursday, Surgical; Friday, Throat.

Westminster Hospital, S.W., Tuesday, 4.30 p.m.—Demonstration on Some Clinical Aspects of Arthritis.

DUBLIN.

FRIDAY, MAY 16TH.

ROYAL ACADEMY OF MEDICINE IN IRELAND—Section of Medicine.—College of Physicians, 8.30 p.m.

MONDAY, MAY 19TH.

ROYAL COLLEGE OF SURGEONS.—Fellowship Examination commences.

Appointments.

BERKELEY, COMYNS, M.B., B.C.Cantab., M.R.C.P.Lond.; Lecturer on Practical Midwifery at the Middlesex Hospital.

BROWN, E. HAROLD, M.D.Brux., Major I.M.S., Clinical Assistant to the Chelsea Hospital for Women.

BUTLER-HOGAN, J. F., B.A. R.U.I., M.D.Brux., D.P.H.Camb., &c., Medical Officer of Health to the Tottenham Urban District Council.

DENNING, C. E., L.R.C.S., L.K.Q.C.P.Irel., Certifying Surgeon under the Factory Act for the Epping District of Essex.

GOUGH, WILLIAM, M.B., B.Sc., L.R.C.P.Lond., M.B.C.S., House Surgeon to the Hospital for Children and Women, Leeds.

HICKS, CHARLES, L.R.C.P. & S. Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory Act for the Horsmonden District of Kent.

IVENS, FRANCES, M.B.Lond., late Clinical and Assistant Pathologist, House Surgeon to the Royal Free Hospital, Gray's Inn Road.

JONAS, HERBERT CHARLTON, M.B., B.S.Lond., M.R.C.S., L.R.C.P., Honorary Medical Officer to the Barnstaple and North Devon Infirmary.

LENEX, LYDIA ANN, M.D.Brux., Oculist in the Medical Department of the School Board for London.

LLOYD, W. F., M.B., B.C.Cantab., Assistant Surgeon to the Windsor Royal Infirmary.

MCDONOGALL, OLIVER, M.B.Lond., House Physician to the Royal Free Hospital, Gray's Inn Road.

NOKE, F. H., M.B.Lond., Assistant House Surgeon to the Metropolitan Hospital.

PURNELL, RICHARD, M.D. St. And., Medical Officer of Health of the Borough of Wells.

RITCHIE, ALEXANDER B., M.B., M.S.Edin., Medical Officer to the Manchester School Board.

SHAW, CECIL E., M.A., M.D., M.Ch., Hon. Consulting Ophthalmic Surgeon to the County Antrim Infirmary, Lisburn.

SODHI, BABA M. SINGH, M.B., Ch.B.Edin., Senior Assistant Medical Officer to the Portsmouth Asylum.

SPOTT, W. H., L.R.C.P. & S. Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory Act for the Caton District of Lancashire.

Vacancies.

Abbeyleix Union.—Medical Officer. Salary £100 per annum, and usual vaccination fees. Also a Medical Officer of Health. Salary £20 per annum. Applications, with testimonials, to James Finnegan, Clerk of Union. (See Advt.)

Clogher Union.—Medical Officer. Salary £100 per annum, with Registration and Vaccination Fees. Also a Medical Officer of Health. Salary £15 a year. Applications to Thomas Turner, Clerk of Union. (See Advt.)

County Asylum, Whittingham, Lancashire.—Junior Assistant Medical Officer. Salary £150; furnished apartments, board, washing and attendance provided. Applications to the Medical Superintendent.

Down County Infirmary.—House Surgeon. Salary £80 per annum. Applications to Dr. Tate, Downpatrick. (See Advt.)

Durham County Asylum.—Junior Assistant Medical Officer. Salary £150 a year, with apartments, board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £110 per annum, with board and lodging. Applications to Chas. W. Dickinson, Capt. R.N., Secretary.

Royal Cornwall Infirmary.—House Surgeon. Salary £100 a year, with board (excluding stimulants), and apartments. Applications to the Secretary, 4, Parkvedras Terrace, Truro.

Royal South Hants and Southampton Hospital, Southampton.—Senior House Surgeon. Salary £120, with rooms, board, and washing found. Applications to T. A. Fisher Hall, Secretary.

The Westmorland Lock Government Hospital.—Resident Medical Officer. Salary at the rate of £100 per annum, with furnished apartments, &c. Applications to the Registrar, Dublin. (See Advt.)

Traveller.—London firm of manufacturing druggists invites applications from medical men willing to represent them in India, the Colonies, and the Continent. For further particulars see Advt.

Deaths.

COWIE.—At Bournemouth, on May 5th, John Cowie, M.B., O.M. (of Accrington, Lancs.), aged 44.

FREELAND.—On April 15th, at Parham, Antigua, West Indies, Freeland John Freeland, M.D., L.R.C.P.Lond., M.R.C.S.Eng., L.S.A.Lond., elder son of J. B. Freeland, M.R.C.S.Eng., and brother of Douglas L. Freeland, L.R.C.P.Lond., M.R.C.S.Eng., of Snodland, Kent, aged 40 years.

REDFERN.—On May 8th, at Horton Road, Gloucester, Anne, widow of Charles Redfern, M.B.C.S., of Ventnor, I.W., and only surviving child of the late William Wright, of Shoby House, Melton Mowbray, aged 79.

WHITEFOORD.—On May 7th, at 27, South Hill Park, Hampstead, Ellen Mary, widow of the late Adam John Whitefoord, M.B.C.S., L.R.C.P., &c., and daughter of the late Henry Cole, of Dale, Farnbrooke, aged 55 years.

WILLWAY.—On May 8th, at Grimsby, Ellis Marion, wife of F. W. Willway, M.B.C.S., of the Mission to Deep Sea Fishermen, and eldest daughter of F. C. Channing, Indian Civil Service (retired), of 62, Fellowes Road, Hampstead, aged 29.

CANCER OF THE BREAST :

AN ANALYSIS OF FORTY-SIX CASES WHICH
HAVE BEEN OPERATED UPON AND
SURVIVED THE OPERATION FROM
5 TO 32 YEARS,
WITH REMARKS UPON THE TREATMENT OF RECURRENT
GROWTHS, INCLUDING THE DISEASE OF THE
SECOND BREAST, OPERATIVE AND
OTHERWISE. (a)

By THOMAS BRYANT, M.Ch., F.R.C.S.,
Consulting Surgeon to Guy's Hospital.

In the results I now bring before you, many instances of much longer survival after the primary operation than formerly will be found recorded, and likewise many instances of recurrence of disease after prolonged periods of immunity which are very striking.

Group I.—This includes 17 cases of cancer of the breast relieved by operation which are now alive, or have died without evidence of recurrent disease, five or more years after operation; 4 have died, and 13 are living and in good health. Of the 4 which died—

Case 15 died from an accident, *æt.* 62, five years after the primary operation.

Case 16 from old age, *æt.* 80, twenty years after operation.

Case 14 from acute jaundice, *æt.* 63, fourteen years after operation; and

Case 13 from intestinal obstruction due to gall stones, *æt.* 79, thirteen years after operation. In both of these cases a necropsy was performed, and no evidence of recurrent disease was found.

Of the 13 cases which are now alive, 1 has remained free from recurrence for five years, 1 for six years, 3 for eight years, 3 for nine years, 2 for ten years, 2 for fourteen years, and 1 for sixteen years. Taking the whole group of 17 cases together, there was an absence of any evidence of recurrent disease from five to ten years after the primary operation in 9 cases, and from five to twenty years in 8 cases, 13 of these patients being now alive and apparently well.

I should like here to say that the operation I now do, and have done for many years, is neither the one I was originally taught and have seen practised by my senior colleagues—which was certainly inadequate—where lymphatic glands were rarely removed, or anything more than the diseased breast itself, with the skin covering it when involved; nor is it the more modern operation known as "Halsted's," and made public in 1894, but which should be known as "Moore's," or "Banks's," who advocated the principle of free removal in 1882, not only of the diseased breast with the fat and skin over it in every case, but also of the pectoral muscle, fascia, and lymphoid tissue from the axillary vessels, and which is now known as the complete or adequate operation. My operation is something between the two, but nearer the latter than the former, and I hold with the results

before me that it is a complete and adequate measure under the most favourable conditions.

The Operation Adopted.—My routine operation is to remove the whole gland that is diseased with the skin and fat over the diseased area; when the axillary glands are enlarged to dissect out the axilla and subpectoral spaces, and in every case, for examination purposes, to cut into the axilla and to take away glands or lymphoid tissue which appears to be suspicious, but otherwise not to dissect it out, my incision into the axilla skirting the axillary border of the pectoral muscle. I invariably drain the wound through the axilla for the first two or three days.

The pectoral muscle I dissect clean, but do not remove it, although should disease be found to have invaded the muscle, the diseased muscle must be freely taken away. I regard the removal of the muscle as a routine measure to be unnecessary, and the facts I now bring before you tend to support this view, for I am more impressed by accumulating experience that successful results in operations for cancer are more certainly to be secured by an early operation than by "performing tremendous operations upon practically hopeless cases."

I may say at once that it was from the careful study of Moore's memorable paper on "Inadequate Operations on Cancer," published in 1867 in the fiftieth volume of the "Transactions" of this Society, that I was led to deviate from the practice I had been taught, and to follow, as far as I thought right, in the lines of Moore's suggestions, which have been, without question, the basis of all recent operative procedures.

In more recent times the principle of free removal of cancerous disease has been well brought before the profession by Sir W. Mitchell Banks in papers of great importance published in 1877, 1882, and 1900 in the *British Medical Journal*, and it is to him more than any other writer that Moore's views have become established.

What I regard as a point of more importance than so-called complete or adequate operations is early interference, and in my sanguine hours I have imagined, with Sir Mitchell Banks, what the results would be if all cancers were thoroughly excised when they were no bigger than peas, or, as I would prefer to say, when the disease is in its very early stage.

Indeed, I am fairly sure that it has been from my acting upon this principle that I am enabled to bring before you to-day the satisfactory results of treatment which my groups indicate, for in Group I., in which there are 17 cases tabulated, the disease was in most of them in an early stage of development when submitted for operation. The disease appeared, when I first saw the cases, as a lump in the breast without skin implication or lymphatic glandular enlargement, and in which the question arose as to the lump being due either to the presence of a cyst or early cancerous infiltration, for at this stage of the tumour's growth the question could only be settled by an exploratory incision.

Under such circumstances an exploratory incision was made into the lump, and when cancer was recognised the gland was removed. Under these circumstances the good results which have been recorded are to be explained, and they are certainly satisfactory. They are, moreover, what I expected they would be when I

(a) Abstract of paper read before the Royal Medical and Chirurgical Society.

operated, for in 1900 I wrote a paper for a sister society on Cysts of the Breast: their Relation, Frequency, Diagnosis, and Treatment, and in composing it I analysed 242 consecutive cases of breast disease, as they had recently appeared before me in private practice; 163 of these cases were registered as solid tumours or examples of cancer or sarcoma, and 67 as cases of cystic disease.

Of these 163 diagnosed as solid tumours, 126 were operated upon, and out of the 67 examples of cyst disease 44 were operated upon, the percentage of cyst disease to cancerous disease being 25 to 74; the conclusion becoming clear that out of every four cases of breast disease, more or less simulating cancer, one will prove to be an example of cyst disease.

I went, however, much further, and was able to show that if we eliminate from our consideration all such examples of cancerous tumours of the breast as are so well marked as to forbid an error in diagnosis being made, and apply our argument to those alone in which there is only a lump in the breast gland without any collateral symptoms to support a diagnosis of cancer, it would not be wrong to conclude that in every two cases of this kind one will be cystic and the other cancerous.

In these cases of early cancer an exploratory operation was undertaken, and when the tumour was found to be cancerous the gland was removed by the mode of operation I have described, the operation having been undertaken at the period of the tumour's growth, after which the most favourable result might be expected. In all of these the axilla was explored but not dissected, the incision I adopt allowing the finger to explore the subpectoral spaces.

In all of these cases the whole gland was removed with the fat over it and integument. In all of these the pectoral muscle was well cleaned, but not removed. In a few of these only were enlarged lymphatic glands found. In all of those early cases microscopic evidence was sought and found to correspond with that which the naked-eye appearances had suggested. In fact, in the majority of the cases of this group, as well as in many in Group II., the same remarks are applicable. The disease in all was palpably cancer, and the success recorded is due to its complete and early removal.

Group II.—This group includes 19 cases of cancer of the breast relieved by operation, and followed by recurrence in the seat of the primary operation.

In 3 of the cases (Nos. 12, 17, 18) recurrence took place in the scar of the primary operation, and a second operation was performed one year after the primary; 2 of these 3 cases were well and in good health four years later, and in the third case ten years later.

In 9 cases recurrence occurred from three to seven years after the primary operation. In 3 of these no second operation was called for.

In one of the 3 cases (Case 4) the recurrent disease appeared as tubercles in the flaps three years after the primary operation, and spread slowly for nine years, when bladder disease appeared. In another (Case 1) the recurrence showed itself as a sternal growth six years after operation. In the third case (No. 2) chest symptoms appeared seven years after operation.

In the 6 other cases second operations were undertaken three, three, four, five, five, and seven years respectively after the primary. In one (19), three years after the first operation, a tumour was removed from the axilla, and the patient died six years later from lung disease, *æt.* 65, having survived the first operation nine years. In Case 14, where a second operation was called for three years after the first, the patient was well six years later. In Case 15, where an interval of four years had passed between the first and second operation, the patient was well six years later. In a fourth case (6), where a second operation was called for five years after the first, a recurrence took place after a second five years, when chest symptoms appeared. In the fifth case (13), where a second operation was performed five years after the first and a third small one two years after the second, the patient was active and in good health twelve years after the first operation and five after the last. In the sixth case (16), where a second operation in the scar was performed seven years after the first operation, the

patient was well in all ways five years later, or twelve years after the breast was removed.

Of the 7 other cases of this section of the group the intervals between the first operation and a recurrence were from ten to thirty years.

Group III.—This group includes 10 cases of recurrent disease after operation in which the second breast was involved, and 4 cases in which the breast disease was associated with cancer of other parts of the body.

In 4 of the 10 cases (Nos. 22, 24, 26, 29) the second breast was attacked about two years after the first had been removed. In 1 (No. 27) of the 6 other cases the second breast became diseased three years after the primary operation. In 2 others (25 and 28) ten years elapsed before the recurrence appeared, and in the other 2 cases (Nos. 21 and 23) the interval between the primary operation and the appearance of the disease in the second breast was respectively twenty-three and twenty-four years, the recurrent disease having in both these cases involved at the same time the scar of the first operation, this fact suggesting to the sceptical mind the truth of the view that the primary disease had been cancerous.

In 4 of these 10 cases the second breast was not removed, the local disease having been extensive and inoperable. In Case 21 the patient was *æt.* 67; in Case 23, *æt.* 80; in Case 29, *æt.* 48; and in Case 27, only *æt.* 38.

In the remaining 6 cases the second breast was removed. In 1 (20) no signs of return were to be traced six years later; in Case 24 no signs of return existed five years later; in Case 26 the patient was well two years later, and in Case 28 three years later. In Case 25 there was no recent history.

I propose now, in order to make the questions respecting these Groups II. and III. of recurrent cases clearer, to analyse them further, and to subdivide them in order to show: First, the length of the interval that existed between the first operation and the recurrence of the disease. Secondly, as to the seat of the recurrence. And, thirdly, as to the duration of life after operative interference.

Cases of Recurrence not requiring Operation, Group II.—In this group of 8 cases 5 had survived the primary operation from six to thirty-six years, 1 had died from lung disease nine years after operation, 1 was evidently suffering from bladder disease twelve years after operation, and a third sinking with chest disease ten years after operation—all, it may be assumed, of a cancerous nature, the 8 cases having respectively survived the first operation six, nine, ten, ten, twelve, thirty, thirty-two, and thirty-six years, and 5 of these having apparently some years of life before them.

Cases of Recurrence with Second and Third Operation, from Group II.—In this group of eleven cases two had lived five years after the primary operation, and were in good health four years after a second operation. One had lived eleven years after the primary operation, and one was well ten years after the second. One had lived nine years after the first operation, and was well six years after the second. One had lived twelve years after the first operation, and was in good health five years after the second. A second had survived the first operation twelve years, and was well two years after the second. A third had survived the first operation twelve years, a second and a third operation, and six years later had no signs of return. One survived the first operation fourteen years, and was well one year after the third. One case had survived the first operation seven years, had endured a second three years after the first, and four years later died from chest symptoms. One case had no signs of recurrence for twelve years, when, at the age of 72, symptoms appeared suggestive of abdominal disease. One case had lived twelve years after the first operation, and, five years after the second, had some suspicious chest symptoms.

In three of the eleven cases death had taken place or was near at hand seven, twelve, and twelve years respectively after the primary operation. And in eight others there was every prospect of continuous health

five, five, nine, eleven, twelve, twelve, twelve, and fourteen years respectively after the breast had been originally removed.

Seat of recurrence, including 10 cases in which the second breast became involved in the disease, from Group III.—In 5 of these cases no second operation was performed, as in all of them an open cancerous ulcer existed, and it was evident that the sands of life's hourglass had nearly run out. In these cases, two, two, three, twenty-three, and twenty-four years respectively had passed before a recurrence of the disease had appeared, and the patients were, when seen with the disease of the second breast, 37, 50, 55, 66, and 80 years of age. In the second 5 cases the second breast was removed. In 2 of these the interval between the removal of the first breast and the recurrence of the disease in the second breast was two years, and both patients, who were at the second operation 52 and 57 years of age, were well and free from disease five years later. In Case 20, where the interval between the first operation and the recurrence in the second breast was four years, and the patient was aged 54, there were no signs of recurrence six years later. In Case 28, where the interval of recurrence was ten years, and the second operation was performed when the patient was 48, the breast and enlarged axillary glands being cleared away, there were no signs of a return of the disease three years later; and in Case 25, where the same period of ten years had passed before the second breast was removed, when the patient was 50, a good recovery followed the operation, but there is no later history.

Taking the 10 cases, however, as a whole, it appears that while in 3 instances where recurrence took place in the second breast within three years of the operation upon the first, surgical interference could do but little, as in 2 other cases where the subjects were 66 and 80 years of age.

It must be recorded that in 2 others where recurrence took place in less than three years, the patients respectively being 52 and 57 years, there were no indications of recurrence when last seen five years subsequently, or eight years after the primary operation. In Case 20, where the second breast was removed four years after the first, the patient was well six years later, or ten years after the primary operation; and in Case 28, where the interval between the removal of the first breast and the second was ten years, the patient was known to be well three years later, or thirteen years after the first operation.

Conclusions.—If we look at these results as a whole it will be evident that the interval which may take place between the primary amputation of a breast for cancer and its recurrence in the scar or second breast, when such occurs, is most uncertain. That whilst in half the cases tabulated recurrence took place in five years or less, in the second half the interval before recurrence appeared varied from six to thirty-two years; and that in at least two-thirds of these cases it occurred after ten years; and also that when second or third operations were undertaken the prospects of life were not bad.

With respect to the seat of the recurrence, it seems that such appeared in or about the scar of the original operation in 14 cases; in the scar and axilla in only one case; in the sternum in 3 cases; in the second breast in 10 cases, and in 5 of this 10 the scar of the first operation was likewise involved.

I would here ask the surgeons who advocate the clearing out of the axilla of all lymphoid tissue as a rule of practice in every case to consider the fact given above; in only 1 case was the axilla cleared out in an operation for a recurrent affection, and, as already described, it is not my custom to clear it out in all; and yet these results do not suggest an inadequate operation.

I bring this paper before the profession with no little pleasure, for it shows that operations for cancer of the breast, when undertaken at an early period of the disease, are not so unsatisfactory in their ultimate results as we have been led to believe. To have been able to tabulate in Group I. 17 cases of operation without evidence of recurrence in 9 cases from five to ten years, and in 8 cases from ten to twenty years after the primary opera-

tion, and to add that 13 out of these 17 cases are now alive and well, with probably some years of enjoyable life before them, is somewhat startling.

To add to these conclusions the assurance that should recurrence of disease appear after the primary operation, the prospects of prolonged life without second or third operations, are neither unreasonable nor unsatisfactory; for only 2 of the 8 cases so tabulated had survived the first operation less than ten years, and 6 had survived from ten to thirty-six years, and 5 of these had apparently some years of life before them.

To show, moreover, that when recurrence of disease takes place and has been treated by second or third operations much benefit may be conferred, is likewise encouraging, for if undertaken as soon as recurrences appear, they are often followed by fairly enjoyable life, for in five or six of the cases the patients were well and in good health five or six years after these operations.

Where the second breast has become involved a like principle of practice is also suggested. In 4 out of the 10 cases no operation was justifiable, but in 6 cases the second breast was removed, and in 4 of these cases there were no indications of recurrent disease five years, six years, two years, and three years respectively; so that it may fairly be said that operations on the second breast are not only justifiable, but conducive to prolonged life. For my own part, I am so much more satisfied with the results of my own practice since I have put together the materials embodied in the paper I have just read, and brought out the results of its analysis, that I do not feel disposed to deviate from it in any great degree unless the advocates of what I must describe as an over-zealous practice can prove to me that I am wrong and that they are right by the publication of material facts better than those I have now recorded.

By way of summary I should like to express my conviction that the results of operations for cancer, whether of the breast or elsewhere, would be much better than they now are if they could always be undertaken during the early development of the disease, as illustrated by the majority of the cases; that every breast tumour, neither clearly inflammatory nor encapsuled, which seems to involve gland tissue, and may therefore be cancerous, should be at once explored and removed if found to be cancerous, with the whole gland; and that recurrent growths when localised should be similarly treated.

In advanced and neglected cases, where the lymphatic glands and covering integument are involved, Moore's, Banks's, Halsted's, or Gould's so-called complete operation may be called for, but its results are not by any means so likely to be as favourable as those I have reported. Lastly, in cases of recurrence not favourable for operation, unless the removal of the ovaries can be shown in the future to be successful, the X-rays should be employed, for the benefit which has been derived by this treatment when judiciously applied by men of understanding has, in my own experience, been so successful as to raise hopes which I hardly like fully to express, and at the same time seems to be free from danger or serious consequences when utilised by those who know the dangers of penetrating rays carelessly employed, and the difficulties with which the practice bristles. I must, however, add that the influence of the rays, to make them effective, must be maintained for several months after it has seemed to be beneficial; a three-months course, with about three applications a week, appears to be the shortest from which any permanent good is to be expected, and this treatment is full of hope.

DR. BRENDON MCCARTHY, who assisted Dr. Wm. Smith, of Bentonport, in his heroic feat of transferring the fever-stricken patients from Arranmore to the mainland, has been appointed a medical inspector under the Irish Local Government Board. It will be remembered that Dr. B. McCarthy was the recipient of the Arnott Gold Medal on March 17th last.

A BILATERAL INTRALIGAMEN- TOUS FIBROMYOMA SHOWING EXTENSIVE MUCOID DEGENERATION. (a)

By ALFRED J. SMITH, M.B., M.A.O., F.R.C.S.,
Professor of Midwifery and Diseases of Women, Cecilia St. Medical
School; Gynaecologist, St. Vincent's Hospital, Dublin.

THE case I am about to relate will, I hope, prove of interest to the Fellows, the more so that, after searching through the "Transactions," I have not been able to find that a tumour similar to the one I am exhibiting has been shown at any meeting of the Society. An unmarried lady consulted me on April 11th; she had enjoyed good health up to last November, when she noticed that her abdomen was rapidly increasing in size. She complained of pain, which she referred to the pelvis and described as of a "bursting" character, causing her great distress and preventing her sleeping. There was no marked interference with the functions of the bladder or rectum, menstruation was regular as to time, but lasted seven days and was profuse. An elastic tumour as large as an eight months pregnant uterus could be felt on external palpation, but the result of bimanual examination under ether was unsatisfactory, as nothing definite could be made out, the vagina was so completely blocked by an elastic mass which bulged through the vulva, and nothing could be found to represent the cervix or os uteri. I operated on April 16th with the assistance of Surgeon Tobin; a large abdominal incision having been made, the uterus with the tubes and ovaries

was seen to nestle snugly between the lobes of the tumour, which was found to be firmly fixed below and at each side by its relations to the peritoneum. To remove it seemed formidable, but, guided by general principles, I ligatured the ovarian arteries at the brim of the pelvis, and by making an incision between the ovarian vessels and the uterine ends of the round ligaments and pushing down the peritoneum so that the ureter, if displaced, would be pushed down with it out of the way and escape damage, I split the capsule and enucleated the tumour; the uterine arteries were then secured and the cervix amputated, and the peritoneal flaps brought together by a continuous top-stitched suture.

Dr. W. Dargan reports: The tumour weighs 10 lbs. It consists of a large semi-fluctuating mass apparently growing between the folds of the broad ligaments, bilobed and symmetrical on both sides. The uterus lies in front of, and to some extent separable from, the tumour; it is of normal size both in regard to the thickness of its walls and the extent of its cavity; the muscular fibres of the

posterior wall seem, however, to shade into the tumour and suggest that the primary origin of the new growth may have been in the uterine wall. Microscopically the structure of the mass is that of a very vascular and cedematous fibromyoma undergoing very advanced mucoid degeneration. When the growth was incised in the recent state a quantity of mucoid matter flowed out, and the trabecular cystic appearance it now exhibits is due to a great extent to the evacuation of these cysts, partially also to large blood spaces.

In regard to the pathology of fibroids of the broad ligament, Roberts ("Gynaecological Pathology," 1901) says: "These tumours have till lately received little notice and possibly represent a class of fibroids distinct from those of the uterus, and at all events not primarily of uterine origin." It is, of course, well known that many fibroids that arise in the uterus may grow out and burrow between the layers of the broad ligament producing great distortion and displacement of the pelvic contents, but true fibroids of the broad ligament probably arise from the muscular fibres which occur in the broad ligament immediately beneath the peritoneum, and are directly continuous with the musculature of the uterus. Hence they have little connection with the uterus except by apposition or slight adhesion, and generally the uterus is not enlarged or altered in any way, but is merely displaced forwards and upwards, as is, I think, well demonstrated in my case. Bland-Sutton agrees that fibroma may develop in the mesometrium, and gives a beautiful illustration of bilateral fibroids of the mesometrium in his "Tumours, Innocent and Malignant," 1901, p. 200, fig. 116.

The specimen I have shown is an interesting and, I think, typical example of tumours of the mesometrium; it illustrates the difficulty of diagnosis, and shows the advantage of a high incision into the capsule as a means of protecting the ureters from injury.

CASE OF DOUBLE RESECTION OF THE INTESTINE FOR INJURY. (a)

By R. LANE JOYNT, F.R.C.S.I.,
Surgeon to the Meath Hospital.

N. C., A YOUTH, æt. 16, was brought to the Meath Hospital, at 7 p.m. on Nov. 13th, 1901. At the time of his admission he was very collapsed but conscious, and shortly after was able to give a very distinct account of the accident he had met with, and this tallied in every particular with that of a friend who was along with him, and of an onlooker.

When riding his bicycle through the Coombe, returning from his work as an engineer's apprentice, he took both hands off the handles of his machine to settle the lamp. He did not in consequence observe a van driving towards him; his friend shouted to him to look out, and just at this moment, as he raised his head, his forehead was struck by the horse and the shaft of the van hit him in the abdomen. He was carried for a few yards on the shaft and then thrown by its rebound clear of the car, the wheel of which did not pass over him; he was laid on the footpath by some men, and although dazed never lost consciousness. He stated that he only felt winded. The accident occurred about half-past six; he was in hospital at seven o'clock and was at once seen by the house surgeon, Dr. C. K. Bushe, who found him in a great state of collapse, pulse weak and thready, and about 70; there were no marks visible on

(a) Paper read at Meeting of British Gynaecological Society, Thursday, May 8th, 1902.

(a) Paper read before the Section of Surgery, Royal Academy of Medicine, May 9th, 1902.

any portion of him, but Dr. Bushe, realising the grave nature of the injury, immediately telephoned for me. He was seen by me twenty minutes later. By this time some reaction had set in, he became warmer and more able to talk, and vomited. There was no blood in the vomit, which was very scanty, owing to his hungry condition. The pulse became full and was now 70, he complained of violent pain at times above the umbilicus, this at first occurred in paroxysms, but afterwards was more or less continuous. I made a complete examination of him, but could find absolutely no mark on him, liver dulness was not absent, there was no dulness in the flanks, no rigidity of the muscles was noticed, and there was nothing remarkable about the belly. He passed water of his own accord, it was free from blood, and rectal examination revealed nothing. He was positive that the shaft struck him above the umbilicus, and that he was not hurt anywhere else, and mentioned to us that he had recently recovered from a fractured patella.

In consultation with Mr. Ormsby, the Vice-president of the College, it was decided to operate as soon as possible, but as the boy's parents resided at Sutton, and as we considered that it would not be detrimental to await their arrival, I had an opportunity for watching the pulse-rate, which in this case was very instructive. It rose in frequency, steadily, five beats in increase in every half hour. While on admission at seven o'clock it was 70, by half-past ten, when the operation was commenced, it was a little over 105.

The patient was anaesthetised with ether by Dr. Bushe; I opened the abdomen in the middle line below the umbilicus, subsequently extending the incision above it and to the left. An enormous quantity of liquid and discoloured blood escaped; I at once allowed the intestines to escape and found that portion of the jejunum was completely torn away from its mesentery for a distance of over 18 ins., the rent in the mesentery extending to its root. In the angle of the tear, a cylindrical clot, the diameter of a pen handle, projected from the torn end of a vessel and pulsated with it. I at once secured this with a ligature. Immediately above the rent was another tear clean through both gut and mesentery, and the upper torn end of the bowel had a hole punched through it about 1 in. above its free end. I removed the part of the mesentery between the two rents, together with the bowel affected, cut the upper end through the healthy bowel, and united them with a Murphy's button. Previous to this I whip-stitched the torn edge of the mesentery, afterwards suturing the two edges together, this I considered advisable to secure any torn mesenteric vessels. I now examined the remainder of the intestines, explored the recto-vesical pouch, the under surface of the liver and stomach, and discovered in the transverse mesocolon another hole through which three fingers could pass. The dependent colon had at this point been so stretched that the muscular coat and bands, together with the peritoneum, had been completely burst open, leaving an exposed tube of mucous membrane intact. This I excised, removing a clear inch on either side. I sutured it by Cheate's method, using a single layer of silk through and through sutures in the first instance, and Lambert sutures to close the longitudinal cuts. During the operation the abdominal cavity was kept free from blood, and cleansed at the same time by douching with hot saline solution. The boy's condition by this time was very grave; his pulse had risen rapidly to 140. I was forced, therefore, to complete the operation as quickly as possible, and on this account it was not as neat a job as is customary after ordinary laparotomies, but except for the appear-

ance of the wound and a little delay in union it did not make any material difference. A gauze drain was left in and removed forty-eight hours later. The whole operation lasted two hours. The pulse rate slowly fell; on the fifth day the temperature rose to 101·8°, unaccompanied by any rise in the pulse rate; the lower bowel was washed out, and eight hours later a copious motion was passed normally. The Murphy's button was passed on the seventeenth day, and the patient made a steady recovery.

The total length of bowel removed, measured without stretching, was twenty-four inches, three inches being transverse colon, the remainder the jejunal portion. This amount, as Dr. Blayney points out in an admirable paper read recently before this Section of the Academy, does not in any material way affect the general nutrition, and in my case the boy seems to be at the present time as well as ever. Nor does the removal of two feet seem very heroic when compared with the cases Dr. Blayney quotes of 4 to 11 ft., but, as far as I am aware, multiple resections are not numerous, and present some interesting points. For instance, I had put in the Murphy's button before I found rent No 2. Would I have been justified in putting in a second button? In point of time it would have been a distinct gain. I may add the sewing took me nearly twice or three times as long as the buttoning. However, former discussions here led me to think the button less suitable to the large intestine where, in a patient just previously in full vigour and health, it might be stopped by faeces, and again in buttoning the bowels one cannot guarantee which button may separate first, and it is quite possible one might block the other.

Of the after treatment I may mention that for the first three days he was fed on nothing but milk and hot water, then nutrient enemata were added; about the fifth day I substituted raisin water, but this was abandoned as it seemed to have a tendency to purge the patient. For the first eight days he suffered a considerable amount of pain, which came on in spasms, sometimes waking him from sleep, but quickly vanishing on his being given sips of very hot water and occasionally small doses of opium. On one occasion he was delirious, and believing that it might be due to the starvation I allowed him a little more milk, some thin arrowroot, and tea at intervals. The delirium at once ceased.

The points in the case to which I may again refer are: The upper rent in the bowel was apparently about the junction of the duodenum and the jejunum, allowing the upper cut end to be easily manipulated outside the abdomen. The intestines were empty at the time of the accident, the boy having had no food since one o'clock that day. He had a previous training as a patient for three months with a broken patella and was easily managed. I was assisted throughout, by the help and advice of my senior colleague Mr. Ormsby, and I owe my sincere thanks to Mr. T. J. Moriarty, my surgical dresser, for his care and attention in the after treatment of the case.

FIFTY LAPAROTOMIES. (a)

By BEDFORD FENWICK, M.D., M.R.C.P. LOND.
Physician to the Hospital for Women, Soho; Consulting Physician to the British Orphan Asylum.

THE operations here recorded were all more or less difficult operations, which, with thirty-five simple cases for the removal of ovarian cysts and uterine fibroids, embraced all the operations of the kind he had done during the last sixteen months. Only two were followed by a fatal result, both hysterectomies,

(a) Abstract of a paper read before the British Gynaecological Society, May 8th, 1902.

the one for malignant disease and the other for degenerated fibroids, and by a curious coincidence these deaths, the only ones in his abdominal work for more than three years, both occurred in the first week of May in 1901 and in 1902; neither of them was due save indirectly to the operation, both happened ten and twelve days after it from heart failure; in the malignant case this was due to old mitral and tricuspid disease; in the degenerating fibroid (shown) the patient's heart, was quite a typical specimen of fatty infiltration and degeneration of the myocardium. Some fifteen years ago he drew attention to the frequency with which fatty degeneration of the heart was caused by the presence of abdominal tumours, and that important fact seemed to be now generally accepted.

The fifty cases comprised twenty-four of ovarian growths, fourteen uterine fibroids, nine of pyosalpinx, and one each of malignant uterine disease, extra-uterine foetation, and extreme abdominal hernia. These cases were arranged in tabular form to avoid unnecessary details, but among the most interesting he might instance a fibroid growth consisting of two lateral masses completely filling the abdominal cavity, connected with each other, and each independently with the uterus by narrow pedicles in which there were not any blood vessels to be found. The nutrition of the growth must have been supplied by the vessels of the omentum, which was closely adherent to it, but had evidently been inadequate, as both masses were completely calcified. In four cases of soft completely interstitial fibroids oöphorectomy had been successful in relieving all symptoms, and twelve months afterwards in each case the uterus had shrunk to nearly the normal size. A subserous outgrowth from the posterior wall of the uterus, which dragged the organ backwards by its weight, completely filled and was so impacted in the pelvic cavity as to resist elevation, was successfully enucleated after division of the capsule from above, and the empty space, which contracted spontaneously in a few minutes to a very considerable extent, was closed with deep and superficial sutures. The ovaries and uterus were healthy and were left intact. The rapid improvement of the patient's general health in this and other cases, when the source of pelvic pressure had been removed, was noted and discussed.

In a valuable paper recently read to the Society, Mr. Stanmore Bishop had described the changes that were to be found in the arteries of the myomatous uterus, and had attributed to them a causal effect in the origin of myomata. With this view Dr. Fenwick could not agree. Some twenty-five years ago he had himself noticed these changes, and in discussing them with Professor Schroeder, with whom he was working at the time, had suggested that they were due to a compensatory hypertrophy of the walls of the vessels to meet the strain thrown upon them by the obstruction to the circulation caused by the increased density of the uterine tissue when affected by myoma. The explanation had seemed so natural and so much a matter of course, it was only on hearing Mr. Bishop's paper that he had remembered it and had mentioned it at once to the operator. The more or less extensive disease of the adnexa so constantly associated with uterine myomata had lately been brought forward as a causal factor in the origin of these new growths, a theory he was unable to accept. He believed that the ovarian artery was the subject of hypertrophic changes similar to those in the uterine vessels, and this necessarily caused congestion and vascular stasis in the adnexa, conditions recognised as factors in inflammation. When such conditions continued week after week, month after month, perhaps even for years, with cumulative effects, was it to be wondered at that when operation was

at last undertaken, the uterine appendages were found to be diseased. Moreover, clinical facts supported this view, the degree of ovarian disease is found to vary chiefly with the degree to which the contiguous portions of the uterus are affected by myomatous change, as was well seen in the case above mentioned of a subserous outgrowth of the posterior wall, the body of the uterus and the ovaries and tubes being perfectly healthy. Too little attention had been given to the importance of the degeneration of fibroid tumours as indications for immediate operation. As regards the diagnosis of the onset of this change, when a fibroid which had existed for years without causing pain, perhaps without even discomfort, the occurrence of pain was, in Dr. Fenwick's opinion, in the vast majority of cases, a symptom of inflammatory change and very often of the formation of intestinal or other adhesions: he thought that other observers would support his assertion that inflammatory changes rarely, if ever, attacked the surface of a fibroid tumour unless some degenerative change was taking place in its deeper structure, and he considered that the occurrence of pain in the vicinity of a previously painless fibroid was of the greatest practical importance as a strong indication for immediate operation. The specimen he had shown that evening had been known to be present for fifteen years, but the patient had had no pain in connection with it till six months ago, and severe pain, for two months only. The degenerative changes approaching so near the surface of the tumour, the inflammatory lesions on the surface itself and the consequent intestinal adhesions, were, one and all, evidences of great value in regard of both prognosis and treatment.

Of the ovarian growths three were large sarcomata, and were removed, but in two other malignant growths involving the omentum and intestines the disease was so extensive that removal was not attempted; the average age of these cases was 56½. In five instances the pedicle had been twisted with the customary clinical and pathological features; two of these five ovarian growths contained pus, the others more or less altered blood, and in every instance they were firmly imbedded in inflammatory effusion. A fact of much clinical importance here also, is that the cases in which there had been most pain were those in which the operation was most complicated by dense inflammatory adhesions.

Of the nine cases of pyosalpinx six were bilateral, three affected the left side only; in every case the tube was much swollen, like a German sausage, and densely adherent to the floor of the pelvis, to the uterus and surrounding parts. In all, the clinical features of importance were the great and increasing pain, the profuse and generally increasing menstrual loss, and the marked loss of flesh and strength which is characteristic of these cases. In every case the condition of the patient three months after operation was remarkably changed for the better; one had gained two stones in weight, another was not recognised by a friend who had lived with her through her illness, on her return from the seaside fat and ruddy instead of wasted and cachectic as she had been before the operation. The more he saw of these cases the more he was convinced of the harm of advising delay in the removal of a constant and pressing source of danger to life, and so great and increasing a detriment to general health and well-being. The greater frequency with which the left tube is affected is a clinical fact he had not seen satisfactorily explained, but which he had so often observed that he believed there must be causal reason for it.

The extra-uterine foetation was not remarkable, save as an example of a woman almost moribund from profuse hæmorrhage, whose life was saved by

immediate and rapid operation ; of the necessity and advantage of prompt intervention in these cases.

The abdominal hernia occurred in a patient from whom he had removed an ovarian cyst three years before, and was due to a fall down a flight of stairs. There was complete retraction of the recti, a protrusion the size of a fetal head, the sac composed of skin and thickened peritoneum, to which coils of intestine and omentum were firmly adherent. The chief difficulty was in separating these adhesions. Then the muscles were dissected back, and the wound closed in three layers. She made a good recovery, with a perfectly strong scar.

Clinical Records.

CASE OF ABSENCE OF THE GENITALIA IN A CHILD DISCOVERED THROUGH AN ATTACK OF APPENDICITIS. — OPERATION AND RECOVERY. (a)

By H. MACNAUGHTON-JONES, M.D., F.R.C.S. I. & E.

I HAVE already recorded two cases of absence of the internal genitalia. These cases I brought before the Obstetrical Society. The one occurred in the instance of a child, *et. 8*. Here I was consulted for complete closure of the introitus, with the exception of an extremely small aperture which led to the urethra. The vaginal canal was found complete. In this case I resected the fold, closing the orifice, making a new vaginal outlet. The uterus was about the thickness of a quill, and a little over an inch in length, and there was complete absence of the adnexa. The second case occurred in a patient, *et. 22*, in whom the catamenia had never appeared. Here the vaginal orifice and the canal were normal, but there was no evidence of uterus save a small knob-like substance in the vaginal roof, and under the deepest *anæsthesia* no adnexa at either side could be detected. The mammary glands were quite rudimentary. I have recently seen two other cases in which the genitalia have been absent. The first was a child, *et. 8½*, that I had the privilege of seeing, with Dr. Farmer, of Lewisham, under the following circumstances:—An active healthy child, she had had no illness until February 16th last, when she was seized with abdominal pain in the afternoon which lasted for the entire night. On February 17th she was seen by Dr. Farmer, the abdomen being distended and resistant, though not tender to pressure. Her temperature was 99.5°, and her pulse 140. On the 18th she had three very offensive motions after a dose of castor oil, and there were periodical colicky pains throughout the day. On the 19th the pain recurred. On the 20th temperature fell to subnormal, the pulse being 112. She was then seen in consultation by a physician, and no definite decision was arrived at as to the exact cause of the symptoms, which were rather obscured. Meantime the bowels were kept fairly relieved, and she took small and increasing doses of belladonna and opium. I saw her on the 26th with Dr. Fraser, and examined her under an *anæsthetic*. By the vagina, bi-manually, both supra-pubically and through the rectum, no uterus could be detected, nor any evidence of adnexa. This was made quite clear by the most careful recto-vesical examination. Through the rectum, above the vagina (not so well felt through the latter), a soft tumour or mass could be discovered, rather sausage-shaped. I advised abdominal exploration, and on the 28th I opened the abdomen. I found the bowel generally in an injected and congested condition, with some soft peritoneal adhesions here and there. These were more particularly apparent at the left side and in the neighbourhood of the sigmoid, in which was a fecal mass doubled over the rectum, evidently that which I had felt through the bowel. No uterus or adnexa were discoverable. The appendix was carried down to the bottom of the pelvis, where it was fixed by adhesions. It was about six inches in length.

(a) Paper read before the British Gynecological Society, May 8th, 1901.

On rupturing the adhesions which attached it some pus escaped. The appendix was removed, and the infected portion of the pelvis having been cleansed with formalin, the abdomen was closed, an iodoform drain being left. An injection was then given by the bowel, and some fecal matter escaped. Things went on fairly well until the fifth day after operation. The long drainage gauze having been removed and shorter inserted. On this day some fecal discharge was perceived coming from the drainage opening in the abdominal wound. The opening was carefully cleansed with formalin and kept patent, but was not otherwise disturbed. On the eighth day after operation the bowels were acting satisfactorily with enema, the wound was healing, and there was neither fecal matter nor discharge. From this time the progress of the case was uninterrupted, with the exception of an attack of cystitis, from which she perfectly recovered, and the child is now well and running about. Mr. Charles Ryall kindly assisted me at the operation.

ABSENCE OF THE VAGINA AND INTERNAL GENITALIA.

A patient, *et. 32*, consulted me for severe pains in the head and periodical pain in the left side. She had complained of her head and some obscure abdominal pains from the age of 18 years. There had never been any catamenial discharge. There was considerable mental depression associated with her symptoms. Sexual instincts appeared to be perfect, and there had been a question of marriage. The mammary glands were fairly developed. The absence of catamenia, and some uncertainty as to the possibility of marriage, had of late distressed her, and her health had considerably deteriorated.

On examination under an *anæsthetic*, I found one small orifice, which proved to be the urethral. The clitoris and labia were perfect, but there was no introitus. On examination by the rectum, and bi-manually, I could find no uterus. I made an incision in the middle line to ascertain if I could light on any vaginal canal, and found that there was none, a musculo-cellular bed existing between the bowel and the bladder. Complete exploration by the opening thus made, as well as by the recto-vesical method, proved that there were no internal genitalia. The patient's position was afterwards thoroughly explained to her, and curiously enough the effect on her mind since she has understood her position has been most salutary. Her headaches were proved to be due to severe eye strain caused by an old unrecognised and high hyperopic astigmatism, which was completely rectified.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD ON FRIDAY, MAY 9TH, 1902, AT THE ROYAL COLLEGE OF SURGEONS.

Mr. THOMAS MYLES, President, in the Chair.

LIVING EXHIBITS.

Mr. D. KENNEDY exhibited a case of excision of the shoulder for necrosis of the humerus, with specimens of the necrosed bone removed. He also exhibited a case of congenital dislocation (sub-spinous) of both shoulder joints, with skiagram.

Mr. JOHN LENTAIGNE (Hon. Sec. of the Section) exhibited a case of tuberculous disease of the ankle-joint, with extensive disease of the tibia, astragalus, and os calcis, cured by radeage. Previously exhibited on March 30th, 1900, exhibited again by special request. He also exhibited a case of Mikulicz's operation: osteoplastic resection of foot.

CARD SPECIMENS.

Mr. W. Taylor: Prostate removed by suprapubic method. Mr. G. Jameson Johnson: Limb amputated for gunshot wound of the femur. Mr. J. Lentaigue: Ossifying chondro-sarcoma of leg involving both tibia and fibula.

**Mr. R. LANE JOYNT then read his paper on a
SUCCESSFUL CASE OF DOUBLE RESECTION OF THE
INTESTINE FOR INJURY.**

which will be found on page 540.

The President said he congratulated Mr. Joynt on the brilliant success of his operation, and he drew attention to the many valuable papers that had been read at this Section during the Session then ending; papers fully up to the standard of the past, and such as compared favourably with those of any other city. He quite agreed with Mr. Joynt in the inadvisability of using a Murphy's button in the operation on the large bowel, especially as one had been used to connect the surgical wound surfaces in the small bowel. The Murphy's button, being liberated earlier in the small intestine, would very probably occlude the Murphy's button in the colon. Suturing the bowel has the great advantage of being free from the risk of occlusion; the surgeon is not kept for seventeen or eighteen days in a state of anxiety waiting for the passing of the button, and with a little practice the bowel could be sutured almost as quickly as the button could be fixed in position. He was much impressed with the fact that the boy was kept for some days without food. Abdominal surgery had taught them that food may be safely withheld from patients for some days. In this case delirium supervened, but was quickly subdued by the giving of some nourishment.

Mr. L. H. ORMSBY (Vice-President of the College) said they ought all to be very much obliged to Mr. Lane Joynt for taking the trouble to come down to them and bring such an interesting case. When he came to assist Mr. Lane Joynt the case looked hopeless. The operation, which took two hours to perform, was watched with care and attention. He agreed that the Murphy button was inadvisable. The lesson he learned from this case was that when a case is seen no time is to be lost. Mr. Lane Joynt's quickness in taking immediate steps saved the boy's life. He (Mr. Ormsby) saw the boy a few days since, and found him looking strong and well. It is impossible to tell by external appearances the serious injury that may have taken place.

Mr. DOYLE said he did not agree with those that held an operation was necessary in every case of abdominal injury; and he related a case of a boy who by a fall from a height on a sharp stone sustained severe abdominal injuries and got diffuse peritonitis, but is to-day alive and well, although his parents refused to allow an operation.

Mr. BLAYNEY said he would like to hear from Mr. Joynt what he thought of Cheate's suture, and what reason he had for employing it in this case? He (Mr. Blayney) looked on it as trustworthy; like the other members he feels they are much indebted to Mr. Joynt for his admirable paper.

Mr. LENTAGNE said he had but to add his congratulations to Mr. Lane Joynt on his very successful operation. He would like to know how he dealt with the hæmorrhage. In his experience it formed one of the most troublesome incidents. He considered the Murphy button altogether unsuitable in section of the large intestine. He was anxious to hear Mr. Joynt's explanation of the not uncommon fact that severe injury to the intestines would result from external violence without being accompanied by any external injury.

Dr. PARSONS said he was much interested in the account Mr. Lane Joynt gave of the gradual increase in the frequency of the pulse, which he (Dr. Parsons) looked on as a valuable sign in perforation of the stomach. Ten years ago he read a paper on this steady increase in the number of the pulsations, which averaged ten in the hour. He would like to hear from Mr. Lane Joynt why he operated on this boy? The boy's appearance was good, his pulse normal, there seemed to be no indication of danger. He would have been inclined to have everything in readiness for operation, but he would have waited for symptoms of injury.

Mr. LANE JOYNT said, in reply, that the President had pointed out one of the great difficulties—want of practice in suturing the bowels. The difficulty, however, was to get bowels to suture, the intestines in the cadaver were so wholly unlike those in the living subject that they were of no use for the purpose. He

purposed trying the suturing on the carcasses of pigs. With Mr. Doyle he agreed that occasionally a marvellous case of abdominal injury does occur and recover without surgical interference; but he looked on such cases as showing how much some natures may suffer and yet the patient survive. He does not, and cannot consider them as in any way justifying non-interference. The Cheate suture he found easy to use, and capable of being rapidly executed. It has the great advantage that in its application the bowel is not mauled. He was fortunate in having no hæmorrhage to contend with. The consensus of surgical opinion is against the use of Murphy's button in excision of portions of the large intestine. One of the difficulties is, of course, the diagnosis of rupture. Gaye's seventy cases, published not long since, throw much light on this; the patients came from a saw-mill, where a circular saw three feet in diameter driven at a rapid rate, from time to time threw off blocks of wood that wounded the workmen in the abdomen, occasioning rupture of the bowels. In none of the cases was there any external injury, yet in all that came Gaye operated and found the rupture. His patient was riding a cycle at the rate of eight miles an hour, and he was struck by the shaft of a van being driven at the rate of about eight miles an hour. Such was the patient's story, and it was confirmed by some onlookers. It was the history of the case that caused him to operate, and even if the boy had told him he was quite well he would have operated, for the amount of injury such violence would cause demanded operation.

The President then called on Mr. ALEXANDER BLAYNEY to read his paper on

TWO CASES OF PERFORATED GASTRIC ULCER.

The first, a girl, æt. 24, was operated on twenty-one hours after the occurrence of the perforation. The aperture, situated on the anterior surface near the pylorus, was readily found and sutured. The abdomen was flushed out and closed without drainage. The patient did well for the first six days, but her temperature then rose, and eventually she died from general peritonitis, due to the bursting of a localised abscess into the general peritoneal cavity. The second, a girl, æt. 21, was operated on nineteen hours after the perforation took place. The ulcer was found on the anterior surface near the cardiac end and lesser curvature. There was a great amount of surrounding induration, rendering suturing very difficult. A portion of the lesser omentum was adjusted over line of sutures. Gause drain was inserted down to this. Early progress most satisfactory. On eighth day a slight rise of temperature took place; fever continued, and on the eleventh day the wound was re-opened and a large perisplenic abscess disclosed. This was drained through the ninth intercostal space, portion of the anterior wound being packed with gauze. Temperature did not subside for a considerable time. Eventually both wounds healed and all stomach symptoms disappeared. However, another abscess formed under the scar, which was opened more than two months after the original operation. Patient is now quite well.

Mr. ORMSBY said the thanks of the section were due to Mr. Blayney for his very interesting paper, and he was sure they were all pleased at the good results that attended his efforts, which were successful from the knowledge gained by his former mistake.

Mr. R. LANE JOYNT said the thanks of the members were due to Mr. A. Blayney for his paper, which was interesting from the long after-treatment necessary, and the way he coped with the many complications. He had prescribed raisin tea for his boy patient, but the lad disliked its sweet taste, and as it purged him it was discontinued. He would like to know how Mr. Blayney got clear of the risk of wounding the pleura. It is easy on the cadaver to recognise everything, but in the freedom given by a small surgical wound in the living body things are not so easy, all the difficulties are not anatomical ones.

Mr. LENTAGNE said the case shows the extreme importance of ascertaining in every case of non-success what it was that caused the non-success. Mr. A. Blayney

saved his second case by formulating a plan from the knowledge he acquired from the unsuccessful one. He quite agreed that some of the poison left after the washing out of the peritoneum caused the abscess. He joined heartily in the congratulations to Mr. Blayney on his excellent paper.

Mr. TAYLOR said it is difficult to find anything to say other than to congratulate Mr. Blayney. He might, however, just point out that the pleura can be avoided by taking the lower border of the ninth rib in the mid-axillary line; the pleura does not come within three finger-widths of this depth.

Dr. PARSONS said two years ago he had a somewhat similar case to that of Mr. Blayney; the area of the perforation was so infiltrated that the sutures cut through, and the wound in the stomach was sealed with a piece of omentum, and a gauze drainage piece inserted. Ten days afterwards the temperature suddenly rose to 101°; the wound was opened, and an abscess found. The patient subsequently recovered; but is still from time to time subject to severe attacks of pain. He would like to know the subsequent history of Mr. Blayney's case. He cannot understand why Mr. Blayney deferred operation so long. The perforation took place at 11.30 p.m. after a large meal of bread and beef, and yet the operation was not performed until 5 p.m. on the following day. Hilton Fagge had laid down twelve hours as the limit in time for success; in this case twenty-one hours elapsed. One of the most important factors in determining the issue is time.

Mr. BLAYNEY said, in reply, that he thanked them for their kind reception of his paper. Raisin tea was liked by his patient and did not produce purging, it is advisable to avoid the use of proteids in such cases. The transverse incision allowed of his pressing outward the skin with his finger at the lower border of the ninth rib, where he felt pretty certain he was free of the pleura. He quite agreed that time is of the utmost importance in such cases. Withal he cannot accept Hilton Fagge's limit, for cases have recovered after thirty hours. All the same the operation, if possible, is best performed within the twelve hours, within which limit 50 per cent. of cases recover.

The Section then adjourned.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, MAY 8TH, 1902.

Dr. HEYWOOD SMITH, Vice-President, in the Chair.

PROFESSOR ALFRED J. SMITH showed an interesting specimen of a

BILATERAL INTRALIGAMENTOUS FIBROMYOMA.

in advanced mucoid degeneration, details of which will be found under the heading of "Original Communications," page 540.

Dr. HEYWOOD SMITH pointed out that to the naked eye the upper part of the uterine muscular tissue seemed involved in the tumour but not the ovaries. Some light might be thrown on the pathological origin of this very interesting specimen during the discussion.

Dr. MACNAUGHTON-JONES commented upon the rarity of intraligamentary tumours so completely dissociated from the uterus as in this case. The case afforded another proof of the necessity for taking quite a new view of the nature of these tumours and their dangers. They could no longer be regarded in the light of simple musculo-cellular structures impairing health only from the ordinary results, such as hæmorrhage arising from them, or from the mechanical effects they might produce on the pelvic or other viscera. The degenerations to which they were liable were met with so often (especially mucoid degeneration, which, as shown by some statistics, was startlingly frequent) that they had to be regarded from quite a different point of view. He would like to know from Dr. Smith exactly how he dealt with the capsule after incising it. He had used the expression enucleation—had he enucleated the tumour from its capsule? He (Dr. Macnaughton-Jones) had not done this himself, but he had seen it done, and, as he had pointed out at a recent meeting of

the Society, this method rendered the removal of the tumour much easier. He would also like to know if these large vascular spaces were present with the mucoid degeneration, as such a multiple form of degeneration was very uncommon. These spaces were of the nature of a telangiectatic degeneration, a most interesting specimen of which had been shown at the Society by the Master of the Rotunda Hospital.

Dr. RICHARD SMITH said he had himself shown to the Society two mesonephric tumours similar to the one before them. One about the same size had burrowed deeply into the broad ligaments on both sides. He asked Professor Smith, what had been the rate of growth, was there any fever or general irritation, and whether the cervix was drawn up beyond the reach of the finger?

Dr. BEDFORD FENWICK drew attention to a bilateral tumour he had brought to illustrate the paper he was about to read. The lower part on the right side was deeply imbedded in the broad ligament; the upper part, on the left, extended well under the ribs, and like Professor Smith's specimen was in advanced mucoid degeneration. The degenerations of myomata were, he thought, due to deficient nutrition from interference with their proper blood supply.

Professor SMITH said, in reply, that the uterus could be lifted almost completely away from the tumour, to which it was attached by peritoneum only and to a very limited extent. It lay with the ovaries and tubes well in front, and having tied the arteries on both sides he had incised the peritoneum and capsule, detached them so as to form anterior and posterior flaps, and enucleated the mass without any difficulty. According to the pathologist's report, there were blood spaces present as well as mucoid degeneration. The patient had been in good health till last November; there was no fever; the vagina was completely blocked and the cervix drawn up beyond the reach of the finger.

Dr. MACNAUGHTON-JONES reported two instances of

ABSENCE OF THE GENITALIA,

which will be found under the heading of "Clinical Records."

Dr. ROUTH said that there was little doubt that many cases of deficient genitalia were not reported either from feelings of modesty or from consideration for the patients; many others were not detected because, as there was no definite disease, no examination was made; his own experience led him to believe that many women were without children simply because they had no uterus. He could now recall the details of two out of the many cases of the kind that had come under his care; both were women in good position, in perfect health in other respects, and with normal sexual instincts; in the one, the vagina was of normal dimensions; in the other, it would only admit the tip of his finger, but he was able to lengthen it by operation, to the great satisfaction of the patient and her husband. The late Dr. Rogers, who like Spencer Wells had a very small hand, was able to introduce the whole of it into the rectum, and complete the diagnosis in that way. Laparotomy for such a purpose was neither necessary nor justifiable.

Professor SMITH had met with both partial and complete absence of the genitalia; the presence of a rudimentary uterus, however, was not uncommon. He was curious for some explanation of the fæcal fistula in Dr. Macnaughton-Jones's case of appendicitis, and could hardly understand how a second gauze drain could have been inserted to replace the first. He seldom if ever used a drain now unless he had reason to expect hæmorrhage.

Dr. S. J. AARONS gave a brief account of a case very similar to Dr. Macnaughton-Jones's second one—a woman of 32 without uterus or ovaries. He asked for more information as to the development of the bust, genital hair, and other marks of puberty in girls in whom the genitalia were partially or entirely absent.

Dr. HEYWOOD SMITH concurred with Dr. Routh that many cases were not reported, and that many married women had nothing in the way of genitalia internal to the vagina; it was a most interesting point that in such the sexual instinct was not necessarily deficient.

Dr. MACNAUGHTON JONES, in reply, pointed out that in one of his cases, while the external genitalia were normal with the exception of a comparative absence of hair, the breasts were quite rudimentary, the gland, in fact, being only represented by a small nipple not larger than that of the male. In the other, the only vestige of genitalia, external or internal, was in the clitoris and labia. Here the mammary glands were fairly developed. In the former case there was a disinclination for male society and an abnormal shyness; in the latter sexual instincts appeared to have been strong. In two cases the only aperture was that to the urethra. In another, while the external genitalia were all perfect the internal were completely absent. A practical point was the necessity for examination when there was emansio mensium before treating patients for assumed amenorrhœa, resorting to drugs or to sending them to ferruginous spas. It was important, both for surgeon and patient to ascertain that there was a uterus present before endeavouring to stimulate its function. With regard to Dr. Smith's question as to how the fecal fistula came, he, Dr. Macnaughton-Jones, could not explain it himself, save by suggesting that the bowel had ruptured from some previous compression and the general peritoneal inflammation which preceded the operation, as in other cases of appendicular abscess. With reference to the gauze drainage, he had not returned it in the manner Dr. Smith thought, but had simply inserted a small portion, wishing to keep the abdominal opening patent. Fashion influenced them in many matters, and now we all resorted to the gauze drain, but he was very doubtful in many cases if the old sterilised rubber tube drain was not preferable. In this instance, with pus deep in the pelvis, he believed, seeing the sequel of the case, that the child would have died had he not inserted a drain.

Dr. BEDFORD FENWICK read a paper on

FIFTY LAPAROTOMIES,

an abstract of which will be found on page 541.

Dr. MANSELL MOULLIN said that as bearing on the very successful work that his colleague, Dr. Bedford Fenwick, had brought before them, and as a fair example of the position of gynecological surgery at the present time, he would draw their attention to a list of operations in the Report of the Soho Hospital for Women for 1901, which included some, if not all, of those upon which this valuable paper was founded. This list included 173 abdominal operations with nine deaths, equivalent to 5 per cent. There were fifty-seven ovariectomies, twenty-one abdominal hysterectomies by the intraperitoneal method, and five myomectomies, without any mortality; one out of twenty-two oophorectomies had been followed by a fatal result, but the other seven deaths had been after operations, not strictly speaking gynecological, but for affections of the liver kidney, intestine, or for malignant disease. In the face of such facts, and especially with regard to the uniformly happy result of the hysterectomies, it must be admitted that we were now in a very different position from that of a few years only ago, when the main consideration in dealing with the fibromatous uterus was, whether it was possible to get a wire round the cervix or not, that we now had means of dealing with these growths, when surgical interference was desirable, without fear of the results, and were consequently in a position to accept the wider indications for such interference, that our improved knowledge of the serious consequences of these tumours upon the well-being and even life of women had rendered desirable.

Professor SMITH said he had had good results from oophorectomy, but now preferred to remove the uterus. He had up to the end of last year done 114 hysterectomies without a death, and had not had any fatality since, but it was no longer remarkable for an operator to have a series of one or two hundred cases without any mortality, and what we had to consider chiefly now was to avoid morbidity, and to secure certain cure and a rapid recovery free from pain, treating each individual case upon its own merits.

Dr. RICHARD T. SMITH had heard of the climax of

surgery being attained at a time before hysterectomies were performed or the skull opened for lesions of the brain, and had no doubt that there was still room for improvement in the methods and results of gynecological work. He was in the habit, in cases in which collapse was to be feared, of administering strychnine hypodermically for a fortnight or so daily before the operation, and with good effect. The very beneficial effects of saline solution in collapse encouraged one to deal with cases in which one would formerly have hesitated to operate. He had found oophorectomy effective in cases of hard fibroids, but not in soft ones.

Dr. MACNAUGHTON-JONES joined in congratulating both Dr. Bedford Fenwick and Dr. Mansell Moullin on the statistics which they had brought forward. At the same time he thought that no matter how successful were the results of hysterectomy, we should not under-rate the gravity of the operation. He would like to know from Dr. Bedford Fenwick his practice in a few matters. The first was with regard to anaesthesia. What anaesthetic did he prefer? He (Dr. Macnaughton-Jones) had now for six months used no anaesthetic save chloroform in abdominal operations, and so far he had been pleased with the results. Secondly, with reference to the bowel, which he himself looked upon as one of the most serious post-operative questions to be decided. When did Dr. Fenwick give an aperient after operation, what aperient did he prefer, and how did he deal with the bowel when there was difficulty in moving it? Thirdly, how did he deal with post-operative sickness and vomiting? These were practical matters of the greatest moment.

Dr. HAYWOOD SMITH agreed as to the good effect of oophorectomy in certain cases of fibroid tumours. Moreover, patients sometimes were unwilling to submit to the more serious operation. He thought that the term coeliotomy was so much more correct that it should always be employed in regard to the operations they were considering. As to the case of abdominal hernia, he would ask whether the abdominal wound after the previous ovariectomy had been sutured in three layers or otherwise?

Dr. BEDFORD FENWICK, in his reply, said that without the great assistance he had derived from the experience and technical skill of his colleagues, Dr. Richard Smith and Dr. Mansell Moullin, he should not have been able to offer them the paper he had read. The statistics given by Dr. Mansell Moullin were very valuable as showing the advantage of specialism in gynecological work as elsewhere, and as they were all well aware compared very favourably with the results of such work at general hospitals. He had no doubt whatever as to the good effect of oophorectomy on certain fibroids, and in every instance in which they had adopted it within the last four or five years, the tumours practically disappeared. He agreed with Dr. Macnaughton-Jones as to the inevitable risks of hysterectomy and never disregarded them. At the Soho they always used gas and ether; many patients did not bear chloroform well, and personally he disliked its depressing action on the heart. With regard to ether, he had noticed the extremely strong smell of the first vomit of patients to whom it had been given. As much of the sickness after operation was due to regurgitation of bile, he gave his patients 5 grs. of calomel the night before the operation, as well as the ordinary purge. If bilious vomiting did occur nothing seemed to do so much good as a teaspoonful of bicarbonate of soda in half a tumblerful of warm water, but if the sickness persisted on the second day he found that white of egg internally, and the application of a mustard leaf to the epigastrium invariably afforded relief. He always opened the bowels; if, on the second day there was any rise in the pulse, he gave 5 grs. of calomel, followed four hours later by sulphate of soda, or, if desirable, substituted 1 gr. of calomel every hour till it acted. If the pulse did not rise above 90 he did not give anything on the second day. The patient was fed on milk and water. As to closing the abdomen, some of his colleagues used the three layer suture, but he did not see any advantage in stitching the peritoneum separately, and stitched it with the aponeurosis.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL,
AND OTOLOGICAL ASSOCIATION.

GENERAL MEETING HELD FRIDAY, MAY 9TH, 1902.

Mr. LENNOX BROWNE, F.R.C.S.Ed., Vice-President,
in the Chair.

Dr. WYATT WINGRAVE read the notes of a case of Otomycosis (*Aspergillus Niger*), and showed a microscopical specimen of the fungus.

Mr. MAYO COLLIER exhibited a patient, a man, æt. 63, suffering from Chorea of the Larynx of twelve months' duration, preceded by similar twitchings of the face muscles.—Mr. LENNOX BROWNE suggested that it was a case of reflex irritation, and probably due to the lingual varix which was present.—Mr. MAYO COLLIER thought this might be so, and said he would cauterise the part, and report result at a future meeting.

Mr. MAYO COLLIER read further notes of a case of Optic Neuritis and Mastoid Disease, reporting almost complete recovery. The further progress of the case had confirmed Dr. Hawthorne's diagnosis of thrombosis of the cavernous sinus.

Mr. MAYO COLLIER also read further notes of a case of epilepsy and tinnitus, and reported that since recovery from the surgical procedure which he had adopted, viz., the clearing out of the contents of both tympanic cavities, together with both drumheads there had been no fit for eleven months.

Dr. P. H. ABERCROMBIE showed a case of Left Frontal Sinus Disease of thirteen years' duration, with frequent attacks of excruciating pain and great tenderness over the right frontal sinus, which latter, on exploration, was found to be healthy. Operation, three months ago, had resulted in a cure. He also showed two new instruments (one Dr. Jakins' and the other his own), adapted to the enlargement of the fronto-nasal canal.

Mr. LENNOX BROWNE showed a patient, a man, æt. 22, the subject, since four years of age, of suppurative median otitis in the left ear. There was granulation tissue to be observed springing from the anterior and superior part of the tympanic cavity. The case was shown as one in which removal of the granulations and cauterising was proposed, because their site, together with the complete absence of symptoms, were favourable to such a procedure, in spite of the advice laid down by high authorities that the presence of such granulation tissue was an indication for the immediate performance of a radical mastoid operation.

THE DIAGNOSIS AND TREATMENT OF THE VARIOUS
FORMS OF NERVE DEAFNESS.

The discussion on Dr. Dundas Grant's paper, read at the last meeting of the association, was resumed by Dr. GREVILLE MACDONALD, who remarked that there were many peculiarities in patients the subjects of nerve deafness. For instance, many are extremely hypersensitive to loud sounds and are fond of quiet places; they are very deaf in noisy surroundings, but hear pretty well when all else is quiet. To such, loud noises are actually painful, and in some cases may even induce giddiness. A locomotive whistle affected the speaker in this way. Such patients are extremely sensitive to syringing the ear, and any sudden shock has been known to upset the equilibrium, such as flashes of light and the rapid passing of one of the red mail-carts. Patients with nerve deafness are very liable to attacks of migraine (especially occipital), and this increases the deafness for two or three days. He thought that Dr. Grant's division into anæmic and congestive, was very valuable and was a good guide to treatment. Nevertheless, cases of anæmia were seen presenting signs of congestion of the internal ear, a state of matters no doubt attributable to vaso-motor debility. Similarly, patients often heard better when hungry, and were worse after eating. Depletion was of value to both anæmic and congestive cases, and an aperient was usually beneficial. He considered that the improvement in hearing, after many intra-nasal operations, such as depletion of the inferior turbinal, or removal of septal spurs, could often be accounted for as much by depletion as by the removal of nasal obstruc-

tion. Nerve deafness, with tinnitus and giddiness, was not uncommon in women at the menopause. As to treatment, his experience of pilocarpine had been unfortunate. Rest he regarded as of the very greatest importance, especially in recent cases. Bodily fatigue increased the deafness, as did mental depression.

Dr. ATWOOD THORNE confirmed Dr. Greville MacDonald's remarks as to the influence of fatigue and rest in cases of nerve deafness, by the relation of an interesting case, showing great variation in hearing power before the day's work and at its conclusion.

Dr. WINGRAVE spoke as to the injurious effects on the internal ear of the toxins of tobacco, and related cases illustrating this.

Mr. NOUBSE related an interesting case of traumatic nerve deafness, in which injury to the labyrinth arose from an accidental wound from a penholder.

Mr. LENNOX BROWNE discussed the confessed difficulties of diagnosis, in spite of the careful employment of even the most refined tests. He thoroughly agreed with Dr. Greville MacDonald's remarks as to the explanation of the occurrence of both anæmia and congestion in the same patient, as well as in the value of depletion, but he could hardly agree that this latter alone explains the improvement in hearing, following the removal of intra-nasal obstruction. He was inclined to think that surgeons were too apt to discount the patient's almost invariable explanation of nausea and vertigo as the result of biliousness; and to put the matter practically, he thought that purgatives and restricted diet constituted a better basis of therapeutics than nerve tonics and nourishment. He had not seen any good result from the administration of quinine in nerve deafness.

Dr. DUNDAS GRANT, in reply, said that he was well aware that he had not dealt fully with the subject in his introductory address, and that much detail had to be filled in. He agreed that congestion of the labyrinth occurred in patients who were anæmic, and related such a case. He had seen puncture of the inferior turbinal do good in cases of nerve deafness, and referred to Dench's statement that there is a direct communication between the veins of the internal ear and the pterygoid plexus. Fatigue undoubtedly increased the deafness. He related a case of neurasthenic nerve deafness where good food and stimulants led to great improvement. He referred to tobacco nerve deafness as undoubtedly occurring. Sympathetic nerve deafness may occur in one ear, following some affection of the conducting apparatus in the other ear, and the ear first affected may require treatment with the view of saving the other. Purgatives certainly were good, and might act by removing toxins from the blood. Strychnine sometimes does harm in nerve deafness. Quinine was a double-edged sword, no doubt. Still it was good in some cases, such as anæmia with exhaustion. Small doses of quinine, as $\frac{1}{2}$ gr., were good in Ménière's disease, and seemed to act as a nerve sedative.

France.

Paris, May 19th, 1902.

CHLOROFORM ACCIDENTS.

At the meeting of the Académie de Médecine, M. Laborde, in referring to the recent discussion on accidents due to chloroform, said that the chloroform vapours, by their irritant action on the naso-pharyngeal nerves, were capable of producing sudden arrest of the heart and of the respiration, and the more especially when the patients were particularly nervous.

In order to prevent as much as possible that cause of death which was always imminent when the chloroform approached the nose of a patient, it was necessary to diminish the extreme excitability of the terminal expansions of the trigemini.

The best means to obtain this end consisted in injecting previous to the operation a Pravaz syringe of the following solution:—Hydrochlorate of morphia, 0.10 centigr.; sulphate of atropine, 0.01 centigr.; sulphate of sparteine, 0.01 centigr.; water, 10 grammes. The painting of the mucous membrane of the naso-pharyngeal tract with a concentrated solution of cocaine would meet the same end. It would be well also to keep by means of a special forceps, the tongue out of the mouth, avoiding thus the possible accident of the tongue falling into the glottis, provoking asphyxia, while the position would be eminently favourable for practising rhythmical tractions in case of necessity.

NEW TREATMENT OF TUBERCULOUS PERITONITIS.

The treatment consists in puncture of the ascites and washing out the abdomen with sterilised water.

Dr. Baylac, who has treated several cases in this manner, read an interesting paper on the subject. Of the ten patients treated six were completely cured and the remaining four considerably benefited. One of the patients, in a very bad condition, was treated four years ago, and for three years and a half enjoyed perfect health; however, last year the ascites returned, and the operation was repeated, but six days afterwards the patient succumbed. It must be said, however, that the patient was given to drink.

His method of operating is as follows:—After washing carefully with an antiseptic solution the abdomen, the patient is placed on the left side, so that all the ascites is accumulated in that region. The large trocar of Potain's apparatus is inserted midway between the umbilicus and the anterior iliac superior spinous process, and the ascites is drawn off. Then through the same trocar three or four quarts of sterilised water, at a temperature of 105° F., are injected and allowed to run off. This operation is repeated three or four times with similar quantities of water, until it returns clear and limpid; from twelve to fifteen quarts of water are generally employed. The wound made by the trocar is finally closed with cotton steeped in a mixture of collodion and iodoform, and the abdomen covered with cotton wool maintained with a bandage. Absolute rest in bed for a few days completes the cure.

The water used for the washing of the abdominal cavity is distilled or boiled, sterilised in the autoclave at a pressure of three atmospheres. It is preserved in the quart bottles (twelve to fifteen) in which it has been sterilised. On one of these bottles the cork with two cocks or taps of Potain's aspirator and armed with a plunging tube, is fixed. By means of the pump air is forced into the bottle, this air compresses the water, and forces it into the abdominal cavity. In employing thus the Potain apparatus, the water is kept free from contamination. At the moment of the operation the bottles are brought to a temperature of 105° F. by means of a sand bath placed at the bedside of the patient so that the liquid arrives in the peritoneum at the temperature indicated.

INCOERCIBLE VOMITING OF PREGNANCY.

Dr. CONDAMIN, of Lyon, treats all cases of incoercible vomiting in pregnant women with enematas of artificial serum, three or four quarts daily, in doses of twelve ounces every two hours. During eight or ten days the patient takes nothing by the mouth (absolute rest of the stomach). If the serum irritates the intestine a few

drops of laudanum are added. M. Condamin has already treated in this way with complete success eight cases, for which otherwise provoked abortion seemed the only remedy.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, May 17th, 1902.

At the Surgical Congress Hr. Behn, Frankfort, A.M., read a paper on

THE TREATMENT OF INFECTIVE PURULENT COLLECTIONS IN THE PERITONEUM.

The speaker set himself to answer two questions. First, how far are purulent affections of the peritoneum to be treated surgically? And second, what principles of treatment are to be adopted? Here we must ascertain what advances abdominal surgery has made. The fear of the peritoneum diminishes with treatment. Regarding measures there is unanimity as to certain points: abscesses near the peritoneum must be opened early; in case of perforating wounds the abdomen is to be opened for the purpose of ascertaining the injuries to internal parts. In severe contusions the case must be most carefully watched, so that the right moment for operation may be selected. In perforation from gastric or intestinal ulcers we stitch up or cut out the diseased part, where it can be done. Finally, in visibly progressing suppurative processes we open the abdomen. Every suppurative process in the abdomen should be operated on. Against this, opposition will be raised. People will say the peritoneum adheres quickly, and leads to encapsulation, so that laparotomy is unnecessary, and then the situation of the collection is of great influence as regards consequences. But this is not always the case. The collection is often encapsuled, and then we may wait a longer time, often properly so, but we cannot depend upon it. Bacteriology and the condition of the blood afford no certain indications. Many physicians are of opinion that in mild cases internal treatment is of service, but not in severe cases. But as the mild cases cannot be distinguished beforehand, and as the grave ones run a fatal course with internal treatment alone, an operation must almost always be performed. In any case operation is the rule and expectancy the exception. Early operation is not dangerous, and it is the only means of avoiding serious peritonitis. Many surgeons say that cases come too late for treatment, operation would be dangerous, and we must wait for developments. But in the peritoneum may be absorbed or it may burst outwardly, but we have no certainty in respect of either termination. The technique favours opening the abdominal cavity. The peritoneum has great resisting powers as regards infection.

Unfavourable results depend possibly on faulty technique. Mostly the abdomen is not opened freely enough, and no drain has been left in, or in consequence of insufficient opening, off-lying collections have been missed. The speaker would lay down the following principles:—(1) A sufficient opening, bearing in mind the possibility of subsequent hernia; (2) efficient washing out; (3) drying of the peritoneum; (4) removal of the focus of infection; (5) efficient drainage. Abscesses are to be shut off by iodoform gauze after

insertion of the drain, and the normal intra-abdominal pressure must be restored. For this reason the abdomen must be sutured closely around the drainage tube. Of 46 cases of abdominal abscess treated surgically 45 recovered, and only 1 died. Some of them were cases of fetid and septic abscess. Of 22 cases of peritonitis he had 9 recoveries, with 13 deaths.

In a recent number of the *Therapeut. Monatsch.* is a paper by Dr. Solt on

ERGOTINE AS A PROPHYLACTIC AND SPECIFIC IN CHILDREN'S FEVER.

He had always used ergotine in his practice in preference to crude ergot, as the latter is so uncertain. The chief property of ergotine is that of exciting contractions of the uterus. Under the influence of the ergotine the flabby softened diseased uterus contracts. Its walls become thicker, firmer, and drier. The lymph spaces become smaller. The relaxed blood vessels also contract. The oedematous soaking of the tissues that precedes the entrance of disease germs can no longer take place. Protection was therefore afforded against the entrance and development of such germs. By small doses of ergotine powerful spasmodic contractions of the uterus are never set up, but normal contractions. They begin in the extreme periphery of the uterus, even in the adnexa and pass on to the cavity of the uterus. The contraction hastens the exudation of the lochia and also of necrosed tissues. After the contraction the uterus does not dilate again so much as before. It cannot take up so much fluid as before, since the superfluous moisture has been expelled by the contraction. If shreds of tissue remain in the cervical canal, they do so only for a very short time. The uterus reacts against foreign bodies lying in the cervical canal even more than when they lie in the body of the uterus. Given prophylactically ergotine protects the uterus against infection from without, and from wounds of the vagina, perineum, and rectum. Naturally the temperature falls also when absorption is prevented. The author also gives ergotine in all cases associated with inflammation and suppuration. In infected suppurating wounds, abscesses, abscesses with pyæmic or septicæmic symptoms, he gives ergotine in place of alcohol. The patients feel better after two or three days, and the appetite returns.

Ergotine has tonic and strengthening properties. The organism disposes of the poisonous materials more readily under its influence, and later on the fewer disease germs are more easily disposed of by the phagocytes.

The author would therefore give ergotine before all operations, and in all cases of fever with exhaustion. During the past seven years he has treated about thirty cases of puerperal fever with ergotine, giving it all through the illness. All the cases recovered with a rapidity he had never before observed. In all cases when the labour has been normal he gives ergot two or three times a day in powder. After each operation or when the patient is suspected of intoxication he orders the following as a prophylactic:—

R Ergotini ana	...	...	50 parts.
Aque distillatæ			
Tinct amara	...	...	15 "

M.D.S.

Ten to twenty drops three times a day, or:

R Ergotini	...	...	50 parts.
M. Aq. Menth pip	...	...	20 "

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, May 17th, 1902.

EPITHELIOMA OF EYELID AND ITS OPERATIVE TREATMENT.

At the "Gesellschaft der Aerzte" Rüdinger brought forward a patient on whom he had operated for epithelioma of the lower lid, which involved the greater part of the lid. He had also supplied the gap by excising cartilaginous pieces from the ear to take the place of the tarsus. No pedicle could be obtained in this operation, but, notwithstanding, an excellent result was obtained. It is unnecessary to add that no eyelashes have yet appeared, although the conjunctiva has united at the margin very neatly, giving an excellent cosmetic result.

The outside of the inserted part has a paler appearance than usual while the conjunctival surface is normal.

Muller questioned whether such good results could be obtained in a partial defect of the lid as appeared in the total case, since the absence of the sphincter in the latter is favourable to repair. For the same reason the operation would be useless in the case of the upper lid owing to the loss of the levator action. In shortening of the tarsal cartilage, such as often occurred in trachoma, Panas' method gave good results.

Elsching thought that slight defects could be easily removed by a trifling canthoplastic operation, either triangular or quadrilateral. Of major operations he thought Rüdinger's very suitable.

INFLAMMATION OF MIDDLE EAR AND THROMBUS.

Alt showed a lad who had suffered from right-sided otitis media for a long time, which had culminated in thrombus of the lateral sinus and jugular vein extending to the subclavian vein. The thrombi were cut down upon, and the temperature fell the following day.

Shortly after the posterior part of the right lung became dull with bronchial breathing, fetid breath, and very high temperature. Three days later, the metastatic abscess was operated on by resecting the sixth rib attaching the lung and pleura to the costal parietes and completing by the Pacquelin cautery. Two days later the normal temperature was again restored. The pus contained streptococcus pyogenes aureus. This case suggests the propriety of tying the jugular vein in order to prevent metastasis such as occurred in this instance.

Knopfmacher related a similar case that came under his notice after an attack of scarlet fever. Metastatic pulmonary gangrene set in with the formation of an abscess which broke into the pleura, producing empyema. No operation was performed, the child recovered and all the exudation became absorbed.

Alt thought the absence of thrombus of the lateral sinus and jugular vein favoured the recovery of the child.

The Operating Theatres.

WEST LONDON HOSPITAL.

FOUR SUCCESSIVE ABDOMINAL OPERATIONS FOR INFLAMMATORY SYMPTOMS COMMENCING IN THE APPENDIX.—Mr. SWINFORD EDWARDS operated on a girl, æt. about 23, who had been admitted three months previously with symptoms of abdominal abscess possibly connected with the appendix. Immediately on admission the abdomen

had been opened below the umbilicus in the middle line. A large abscess was found and evacuated; it ran downwards into the pelvis, and also into the right iliac fossa. On this occasion no attempt was made to discover the appendix. A large drain was inserted, and the patient rapidly improved. When the wound was all but healed, only a small sinus being left, Mr. Edwards proceeded to remove the appendix through the usual incision. He found it buried among adhesions, kinked and truncated. On account of the large number of adhesions which had to be broken down, a gauze drain was left in to be removed at the end of twenty-four hours. The patient made an excellent recovery, but the sinus left by the first operation still remained patent, discharging a little pus. After the appendectomy wound was thoroughly healed the patient's temperature began to rise, and as more pus came away from the epigastric sinus it was thought advisable to drain this abscess through Douglas's pouch; this again was followed by a fall of temperature and alleviation of all symptoms such as pain, &c. A fortnight after this the patient complained of pain in her left lumbar region, especially when she got up; a swelling was found occupying the site of an enlarged left kidney; it was dull on percussion from the front, and felt solid rather than fluid. The patient suffered with some increased frequency in passing water; oxalate of lime crystals were found in the urine, and the amount passed was small, varying between ten and twenty ounces in the twenty-four hours. Taking these facts into consideration Mr. Edwards believed that the girl was suffering with a recent hydro- or pyo-nephrosis due to blocking of the ureter with possibly an oxalate of lime calculus. Accordingly the patient was now subjected to a fourth operation. Having been turned on her right side, the left lumbar region was thrown upwards by the placing of a hard round pillow under the opposite lumbar region. A transverse incision was made in the usual site for exposing the kidney in the lumbar region. After the abdominal parietes had been divided and the peri-renal fat exposed, the operator came upon what appeared to be cystic swelling lying over the tumour and, being apparently a part of it. This was incised on the supposition of its being cystic but flatus escaped showing that the descending colon had been opened; this was verified by seeing its mucous coat. The descending colon had thus been opened, where it was devoid of peritoneal covering. The opening into the gut was immediately sutured with a double layer of sutures one for the mucous coat, the other for the muscular. After a careful search the kidney was found somewhat smaller than normal, almost out of reach under the ribs and quite independent of the tumour. Having opened the bowel, Mr. Edwards thought it well to desist from any further attempt to settle the nature of the tumour; he thought that it would be best left for a subsequent occasion, and that it would then be more easily attacked from the front through the peritoneum. Looking to all the circumstances of the case, he was inclined to think that the swelling was probably inflammatory, being connected with the inflammatory mischief which originated in the attack of appendicitis. The lumbar wound was closed in layers and a gauze drain left down to the site of the injured gut in case any leakage should occur.

With regard to the first operation, he said it was pretty clear the right course had been pursued; had he then searched for the appendix he probably would have disturbed the parts and turned a localised into a general peritonitis. The second operation, namely, that of appendectomy, was, he said, one of considerable difficulty, and took an hour to complete, owing to the number and extent of the adhesions, among which the appendix was completely buried. With regard to the third operation, which Mr. Bidwell kindly performed during Mr. Edwards' absence from town, it was carried out on the lines of dependent drainage, i.e., to provide a drain from a dependent opening. Concerning the present operation, Mr. Edwards considered the question as to how in a future case such a mistake might be avoided: First, when he was in doubt as to the structure to be punctured, he thought it would have been well to have percussed it. Secondly, when the tumour was pressed up in an operation from the front into the operation area, he noticed that the structure taken for cystic did not become as tense as he had anticipated would have been the case in a hydro-nephrotic kidney. Another point was the fact that no kidney tissue had been exposed, which, he said, was quite sufficient to have thrown doubt on the nature of the presenting swelling.

It is satisfactory to say that although ten days after the operation, the patient has a small faecal fistula, it is rapidly healing, and the abdominal swelling is smaller and not attended with so much discomfort.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 6d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d. Half Page, £2 10s. 0d., Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 21, 1902.

THE POLICE AND URGENCY CASES.

THE primary duty of the police force of the United Kingdom is clearly to ensure by every possible means the safety of the public. Speaking generally, the conduct of this civilian body is admirable, and it may be confidently claimed that the social security and freedom of which as a nation we are justly proud is in no small measure due to the organisation in question. At the same time it

is impossible to overlook the fact that certain more or less grave flaws are to be found in our police system. The majority of these defects do not concern us in our capacity of a medical journal, but there is a preventible and dangerous source of error to which we have frequently drawn attention in the columns of THE MEDICAL PRESS AND CIRCULAR. We refer to the deaths in police cells of individuals whose condition of sickness has been mistaken for drunkenness by the police. At the outset certain propositions can be laid down with regard to persons found in the streets in a comatose condition. For example, any such person is in a dangerous position if left alone while in that state, secondly, it is sometimes extremely difficult to determine the precise cause of unconsciousness. Thirdly, a careful medical examination will as a rule prevent serious mistakes. Had these fundamental principles been acted upon at the Streatham police station a recent lamentable occurrence might possibly have been thereby averted. The facts of the case as narrated at the Coroner's inquest present a picture with which newspaper readers are only too familiar. A medical man was found lying in the roadway insensible, and was taken by a policeman to the police station under the impression that he was drunk and incapable. In reality the unfortunate man was seriously ill, but the constable haled him off to the station, and an hour was spent in covering a distance that could be walked in twenty minutes under ordinary circumstances. He was lodged in a cell on a charge of drunkenness without being examined by a medical man, and was seen at half-past one and again at three in the morning, but at four he was dead. As the result of a post-mortem examination the cause of death was attributed to fatty heart and an overloaded state of the stomach. It is not remotely impossible that with proper medical care and attention the life of this unfortunate gentleman might have been saved, at any rate for the time being. At least his relatives would have been spared the pain and distress occasioned by his death amid the sordid surroundings of a police cell, untended and uncared for. The moral of the occurrence is not far to seek. It has been forcibly enough laid before the public time after time, yet the scandal of this police cell tragedy is constantly recurring throughout the length and breadth of the United Kingdom. What are the plain simple precautions that would be recommended by medical authorities in order to avoid error in cases of suspected drunkenness? They are few and simple. First, let every unconscious prisoner brought to a police station be examined by a medical man as a matter of routine, and let the cost if necessary, be borne by the police. Secondly, let no unconscious patient be left alone, regardless of the origin, or the supposed origin, of his condition. It would be better to pay for the medical examination of a hundred drunken men than to permit one person to die an ignominious death through want of a little reasonable care. There would be no great

difficulty, moreover, in arranging the supervision of several unconscious persons by a competent attendant in a small ward attached to the police station for the reception of such cases. There is a strong appeal to the instinct of self-preservation that is common to all mankind in the desirability of means of effectual prevention of such disastrous errors on the part of the police. What happened to-day to our unfortunate brother medical practitioner in a London suburb may be the fate of any member of the community to-morrow in any part of the Kingdom. It is to be hoped that some of the medical members of Parliament will call the attention of the House of Commons to the Streatham case, and that before long someone will introduce a short Bill directing the police to call in medical assistance to all prisoners who are brought to police-stations in semi-unconscious or unconscious conditions. In this simple manner the security of the public may be advanced in a manner befitting the humane and scientific tendencies of the age.

ARSENICAL BEER AS A CAUSE OF CANCER.

PUBLIC and professional attention has been recently focussed on the importance of maintaining a strict watch on the manufacture of malt liquors. The extensive suffering and numerous deaths resulting from the contamination of beer in the North of England with arsenic have been thoroughly investigated by Royal Commission. And much of the evidence has gone to show that arsenic in deleterious quantities has for long been present in many of the widely distributed malt liquors. At least one observer has gone so far as to contend that practically all the peripheral neuritis so long prevalent in Manchester and district has been "arsenical" rather than "alcoholic." It has also been shown that the cases of so-called "alcoholic heart" for many years met with in Lancashire and the adjacent counties in large numbers have in all probability been due, at least in part, to a degeneration in the cardiac muscle dependent on the presence of arsenic. It is therefore not unreasonable to ask if the presence of arsenic in our popular malt liquors can have contributed in any way to the lamentable increase in cancer. This matter is dealt with in a very suggestive article in the current number of the *Polyclinic*. The long-continued use of arsenic has been clearly shown by Mr. Jonathan Hutchinson and others to be instrumental in initiating cancerous processes. References to this work are given by Kelynaek and Kirkby in their monograph on "Arsenical Poisoning in Beer Drinkers." The long-continued administration of arsenic undoubtedly produces "arsenic-cancer," which almost invariably takes the form of an epitheliomatous formation on the skin. Now, it seems more than probable that for the last few centuries certain sections of the community have been habitually consuming arsenical salts in their malt liquors. The revelations made before the Royal Commission

as to the almost inevitable presence of arsenic in all beer made from malt dried over coke seem to clearly warrant such a view. If, therefore, the continuous use of arsenic in medicinal quantities undoubtedly predisposes the skin to multiple cancer there is no impossibility in the suggestion that it may do the same for other tissues, for mucous membranes, and even the viscera when taken in small "dietetic" quantities. Without denying the importance of innate and acquired tendencies, it seems quite feasible that arsenic may have exerted some influence in the growing increase of cancer. The question now raised furnishes material for much investigation. It will be necessary to ascertain whether the recent supposed increase of cancer has occurred chiefly in beer-drinking populations, and whether the risk of arsenical contamination occurs in all countries where beer is made. It is necessary also to inquire if arsenic may not gain access to the organism in other ways. That arsenic can predispose to cancer is clear. That arsenic may readily gain access to food-stuffs has been shown without possibility of denial. The question now to be settled is whether the arsenic taken unwittingly in articles of food can in any way prove instrumental in assisting the greatly increasing tendency of persons in this country to develop cancer. The matter is of such importance that we hope the Royal Commission now sitting will not neglect this aspect of the case.

CARELESSNESS AND IGNORANCE IN DISPENSING.

THE circumstances revealed in the course of the recently terminated inquiry relating to the death of Dr. Ingledew, of Woolwich, are calculated seriously to shake the confidence of the public not only in respect of the trustworthiness of retail chemists, but also of the system under which medicines are dispensed by medical men. It appears that Dr. Ingledew, who was addicted to the morphia habit, sent to the shop of a Mr. Goldthorpe, a Woolwich chemist for a drachm of the drug. The manager, a qualified pharmacist, told his assistant to get the bottle from the poison cupboard, and the assistant then weighed out what he supposed to be morphine. Dr. Ingledew, on receiving the packet, handed it to his dispenser, who prepared a solution. This was swallowed by his master, who immediately exclaimed that strychnine had been sent instead of morphia, and Dr. Fuller was called in. The latter seems to have been in complete ignorance of the circumstances of the case, and attributed death to shock, but further inquiry conclusively established the fact that death was due to strychnine poisoning. The first point that calls for comment is the carelessness of the chemist which shows how delusive is the protection afforded by the proviso that poisons shall only be sold under the superintendence of a qualified pharmacist, for in this instance the superintendence only amounted to telling the assistant where to find the bottle. Even more extraordinary is the admission

of Dr. Ingledew's dispenser that he was unable to distinguish between morphine and strychnine, with the result that although the powder handed to him by his principal struck him as being very different to that previously supplied, he did not think it necessary to call attention to the fact, and thereby innocently but ignorantly conducted to his master's death. Well might the coroner observe that for a person totally ignorant of drugs to undertake to dispense them was almost criminal. The worst of it is that such conduct is perfectly legal, since no restrictions are placed by law on the employment of unqualified and inexperienced dispensers by medical men. This lamentable occurrence reinforces the argument that we have so often advanced, viz., that the latitude accorded to medical practitioners in respect of the employment of unqualified dispensers is fraught with grave danger to the public. The circumstances in regard to the manipulation of powerful poisons are exactly the same in the surgery as they are in the pharmacy, and a medical man who deliberately employs an inexperienced person for such purpose incurs very grave responsibility. Looking at the matter from a broader point of view it is obvious that the law does not afford the public the measure of protection which the public is entitled to expect. The verdict convicts the chemist of neglect, in that he failed to verify the nature of the poison dispensed by his assistant, and the assistant of carelessly supplying strychnine in mistake for morphine. But there the matter apparently ends, the victim is buried, and matters go on as before. In any other country than this such a mistake would entail very severe professional and pecuniary punishment on those responsible for the disastrous mistake. Here the absence of any felonious intent is held to render the parties concerned virtually irresponsible, for the mere censure of the Coroner's jury, which in this instance seems to have been dispensed with, cannot be regarded as in any way an adequate recognition of the gravity of the mistake.

Notes on Current Topics.

Dust and Mud.

THE general interest which the war against consumption has excited among the public may possibly lead to the general recognition of the fact that dust is a powerful factor in the dissemination of disease, especially in the crowded centres of population where the dust is composed of organic particles potentially endowed with pathogenic properties. Municipal authorities do not appear to have passed the stage of regarding the conversion of dust into mud as the ultimate precaution required of them, though it must be obvious to the least scientific among them that they are practically exchangeable terms, the phase of transition being so short. Dust is not only capable of conveying infection directly, but it is injurious in virtue of its irritating action on the respiratory passages. In the provinces the high-speed motor car has intensified

the evil and is rapidly rendering certain health resorts in the south of France uninhabitable for invalids. In the Riviera, which appears to be the happy hunting-ground of this exhilarating vehicle, experiments are being carried out with the object of minimising the dust nuisance by "watering" the roads with crude paraffin, diluted tar and similar glutinous and inoffensive products. The dust is thus converted into a sort of dry paste, excellent for vehicular traffic, whatever the deteriorating effects may be on the rubber-shod wheels of cycles and motor cars. The only conceivable objection is the odour, for, however harmless that of paraffin or tar may be, it is not exactly what one goes to the Riviera to enjoy. Tar water would seem to be an ideal mixture for watering the streets of cities where the odour would be an acceptable variant to that of horse dung and decomposing organic matter generally. Its special virtues are that it is costless, and that when it dries the non-volatile tar retains the dust on the roadway, whence it can be swept as occasion offers.

Patients' Hospital Records.

A CORRESPONDENT, whose letter we publish elsewhere, makes a suggestion which appears on the face of it to be worthy of consideration. He points out that while the imperative necessity for preserving full and accurate records of a patient's illness is recognised in hospital practice the importance of providing the patient himself with trustworthy information on the subject is lost sight of. This information is peculiarly desirable when operations have been performed on the abdominal viscera, for at present the practitioner who is called upon to attend the patient later on has only the scar and the patient's own garbled history to guide him. Of course this suggestion applies to operations performed in private practice just as much as in hospital, but the private patient, belonging as he does to a more intelligent class of the community, is usually able to furnish his subsequent medical attendants with fairly trustworthy information. We see no reason why each patient on leaving the hospital should not be furnished with a simple statement of surgical facts, the possession of which might avoid the necessity for dangerous delay in the event of urgent symptoms and save the physician the trouble of searching the hospital records.

The Destruction of Plague-Infected Rats.

FOR the French Biological Society, M.M. Langlois and Loir have been experimenting with the object of ascertaining the best methods of disinfecting the holds of ships in cases of suspected plague infection. Like Nuttall, Yersin, and Igato they have found that fleas and flies disseminate the infection. They all found that these insects retain the power of infection for twenty-four hours after feeding on an infected pabulum. They therefore tested the lethal effects of poisonous vapours on these insects as well as on rats. Carbonic acid gas, which has been

recommended for the destruction of the rats, they do not recommend. A prolonged immersion in a 75 per cent. atmosphere of the gas was followed by a recovery of the greater number of the rats, and even the fleas revived when exposed to fresh air. The safest and most trustworthy remedy was fresh sulphurous acid gas, generated in the holds of the vessels by burning sulphur. A three per cent. vapour of this immediately killed the fleas, and the rats died soon after. By increasing the percentage of the acid vapour to 15 per cent. or 20 per cent. the rats were immediately suffocated. M. Chantemesse, experimenting on the effects of the gas on foods and fabrics in New Orleans, found that an atmosphere containing 17 per cent. of sulphurous acid gas did not sensibly affect tea leaves, coffee berries, figs or grapes; but that it injuriously affected butter or cheese. Dyed fabrics were unaffected by gas not exceeding 17 per cent. On these grounds the Society recommend the use of sulphurous acid gas for the disinfection of ships and dwellings.

"Mentioned in Despatches."

A BOOK has just been published entitled "Mentioned in Despatches" (Office of the *Army and Navy Gazette*), which gives the whole of the mentions honours and special promotions in the Navy and Army in connection with the South African campaign which have been gazetted up to May 6th. The share of the Navy is, of course, a small one, being only two D.S.O.'s. In the Army Medical branch, including those consulting and civil surgeons who volunteered for service and Colonials, there have been awarded five V.C.'s, one K.C.B., twenty C.B.'s, two K.C.M.G.'s, forty-seven C.M.G.'s, and thirty-seven D.S.O.'s. Non-commissioned officers and men have thirty-eight Distinguished Conduct Medals, and a Sergeant-Major has been awarded a bar for the medal he already possessed. The volume contains nothing new—all the information has been given in the pages of the *London Gazette* during the last two and a-half years—but everything is presented in a concise form convenient for reference, which will be appreciated by all who have friends or relatives mentioned or promoted in the Army Medical Service for their gallantry and devotion to duty.

Revised Classification of the Causes of Death.

IN the revised list of causes of death which has just been issued by the Registrar-General, we note an omission which does not tend to promote accuracy, in the list of "Accidents of Childbirth." The conditions known as placenta prævia is referred to under that term, but no term is inserted to imply the condition known as accidental hæmorrhage, save so far as it is intended to be included under the general term of "flooding." It would be interesting to note the authority the Registrar-General has for the maintenance of this almost obsolete term, as it is far from obvious why all hæmorrhages associated with pregnancy, labour, or the puerperium save those due

to placenta prævia and abortion, should be included under a term which has almost ceased to be used by writers on obstetrics. A ludicrous example of the lack of official recognition of the term accidental hæmorrhage has been brought to our knowledge. A medical man signed a death certificate "concealed accidental hæmorrhage," with the result that on the certificate being presented to the registrar for the district, this official refused to accept it, and drew the attention of the authorities to the necessity for ascertaining why the occurrence of a death, the result of misadventure (accidental) had been hushed up (concealed) and not reported to the police. Accidental hæmorrhage—so-called—differs widely from unavoidable hæmorrhage, the result of placenta prævia, and therefore we cannot help thinking that it would have been well to have it inserted in the new list as a cause of death.

The Appointment of Extern Examiners at the Royal University.

As will be seen in our report of the proceedings of the Senate of the Royal University, the election of extern examiners has been again postponed. The matter has been referred back to the Medical Committee with the request that they will report further upon it. On a former occasion, the Senate of the Royal University decided that in order to be eligible for the post of extern examiner the candidate must have no connection with any of the Queen's Colleges or with the Catholic University School of Medicine. Now, we learn an attempt has been made to rule out all candidates who have been in any way connected with any Irish teaching institution. This was apparently frustrated, as is only natural. In the first place, it seems to us that such a proposal cannot have been in order, as the conditions under which candidates were to apply had been already laid down, and the applications had been made. If it had been carried it would have ruled out candidates who had been given to understand previously that they were eligible. On the other hand, even if such candidates could be ruled to be ineligible, where are suitable extern examiners to be got? It is surely absurd to say, "Get them from England." For this is but an open confession that the medical profession in Ireland does not contain men capable of examining properly, and in a manner which is fair to all who present themselves for the examination, whether they come from the South or from the North. We do not believe that suitable Irish candidates cannot be obtained, and we trust that at the next meeting of the Senate they may be duly elected.

The Use of Adrenalin in Ophthalmic, Nasal, and Aural Surgery.

THE use of adrenalin in hyperæmia and inflammation of the mucous membranes has considerably increased since the introduction of a standard solution of adrenalin chloride of a strength of 1 in 1,000. Prior to this the difficulty of keeping a fluid extract of the drug ready and active was very great, particularly in hot weather. In nasal work adrenalin

has been found of value not alone in cases of swelling or hypertrophy of the mucous membrane, but in cases where it is desirable to temporarily shut off blood from the nose for operative purposes. Dr. Stanley Green has communicated his experiences of its use to a contemporary, and his evidence is most favourable. He calls attention, however, to the necessity for plugging the nose after operations where adrenalin has been used, as otherwise the cessation of the action of the drug may be accompanied by troublesome hæmorrhage. The relief afforded by adrenalin chloride in photophobia due to certain conjunctival and corneal affections is very great, but Dr. Green utters a word of warning against its use in cases of corneal ulcer, in which condition he considers that it does harm. If adrenalin can accomplish all that is claimed for it in ophthalmic and nasal practice, there is undoubtedly a wide field for its use in many of the other regions of the body.

Mount Vernon Hospital for Consumption.

FACILITIES for the study and treatment of phthisis are rapidly increasing. On the 13th Princess Christian, accompanied by her daughter, Princess Victoria of Schleswig-Holstein, laid the foundation stone of the large country branch of the Mount Vernon hospital, which is perhaps better known under the old name of the North London Hospital for Consumption and Diseases of the Chest. The new sanatorium is situated at Northwood. The site, covering sixty acres, is in a beautiful district. It is about sixteen miles from London on the Metropolitan Railway. No more delightful surroundings can be found North of London. The plans have been prepared by Mr. Frederick Wheeler. Visitors to the Royal Academy may see what the completed building will look like. The wards are to be arranged in linear series all facing south, and will accommodate fifty men and fifty women. The long facade facing south with the balconies above and terraces below will give an elegant and imposing aspect to the sanatorium, and will allow of the free application of open-air treatment. The sanatorium has been made possible through the generous kindness of an old Harrovian, who gives the princely sum of £120,000. Walks two miles and a-half in length, graduated in slope, are being laid out and the institution promises to be the finest in the country. The Mount Vernon Hospital, with its new out-patient department in Fitzroy Square which is to be commenced almost at once, its extended hospital at Hampstead, and the magnificent estate at Northwood for its new sanatorium should prove the best equipped institute in the country for the study and treatment of pulmonary tuberculosis. Only one other branch seems desirable, and that is an urgently needed one—a home for advanced and incurable cases. We hope an American or British millionaire will see in this need a splendid opportunity for still further increasing the splendid work which the Mount Vernon Hospital is so successfully carrying on for the phthisical poor.

Medical Men in Parliament.

THE necessity of representative medical members of Parliament has been repeatedly urged by almost all who have considered the question of medical reform. The chances are remote under existing conditions of any really sound consolidation and amendment of the Medical Acts in the absence of a body of members capable of explaining the professional aspects of the question. In the same way many important matters affecting the health of the community are dealt with imperfectly by the Commons from a similar want of skilled guidance and exposition. The lawyers, who usually keep a tight grip of practical issues, have fallen into no such error, for their influence in the House is always not only adequate but usually also preponderating. So, too, with the brewers, the distillers, the shipowners, the manufacturing capitalists and other possessors of great interests, who one and all bring a powerful organisation into the House whenever occasion arises. The medical profession, however, notwithstanding its enormous aggregate power among the people, remains a cypher in the legislature. In France things are better managed, for there are no less than forty-three medical Deputies in the present Chamber, most of them representing country constituencies. What is done by medical men in France should not be altogether impossible on this side of the Channel. When members of the profession are better organised it is to be hoped that one of their first attempts will be to pay a certain number of medical men as members of Parliament, and to contribute to the expenses of other medical men who may wish to represent Parliamentary constituencies.

Fee for Self-Vaccination.

THE United Kingdom has reaped at least one benefit from the small-pox scare in the shape of a vast addition to the percentage of population now protected by vaccination. It has been amusing to note how many professed anti-vaccinists, both individual and corporate, have rushed hot foot to submit their bodies to the tender mercies of the public vaccinator. The natural result is that large sums of money have been paid by local authorities to those entrusted with the duty of public vaccination. A great amount of clamour has been raised in some quarters on that account, but it is to be remembered that the money now paid to the medical profession in a lumpsum should, properly speaking, have been spread over the ten or fifteen years preceding. Moreover, the ratepayers are getting solid return for their money, inasmuch as protection is thereby secured for a great section of the population. What is spent in vaccination is saved in the maintenance of small-pox patients. While the question of the cost of public vaccination is in the air it is a pity that a gentleman who holds the appointment of medical officer and public vaccinator for Clayton should have chosen this precise moment for bringing his office into ridicule. If the facts be as published the gentleman in question sent in a charge to the Finance Committee

of the Prestwich Board of Guardians of half-a-crown for vaccinating himself. The committee very properly disallowed the charge. Vaccination is not a subject that lends itself readily and gracefully to such clumsy attempts at wit.

The Royal Army Medical Corps.

IN the new regulations for the Army Medical Service which have just been promulgated, the object aimed at has been to maintain the efficiency of the Service by increasing the facilities for professional and scientific study and, as a natural corollary, a new system of examination has been instituted in order to test the practical qualifications of the members of the Corps. The examinations may be grouped under two heads—those of a strictly professional and scientific character, and, secondly, those bearing on the military aptitudes of the professional officer. As we intimated when the draft of the new regulations came before us, these examinations are likely to prove stumbling blocks to many otherwise able officers. Examinations are never agreeable things in themselves, and the prospect of having to submit to them years after having left a medical school will unquestionably be very distasteful to the general run of army medical officers. This fact has not been altogether lost sight of by those who have assisted in the elaboration of these regulations since special facilities are offered for men to prepare for these tests including the proposal to establish a medical staff college, presumably in London, since it is there that the necessary clinical and teaching material is to be found. No exception, we imagine, will be taken to the increased scale of pay, especially as there really seems to be a chance for professional merit to make its way to an extent previously rendered impossible by hide-bound administration. The new regulations, which on account of their detailed comprehensiveness, require to be studied in the original, undoubtedly embody progressive ideas, and will do something to rehabilitate the service in the esteem of the younger members of the profession.

The Diagnostic Value of Tuberculin.

THE use of tuberculin as a diagnostic agent is not popular in this country. The same prejudice to its employment does not exist in Europe and America, at least to the same extent. Dr. C. M. Wood, in an interesting article in the current number of the *Journal of the American Medical Association* finds that tuberculin in doses of '005, carefully increased when necessary to '010, produced no bad effects in simple or complicated tuberculous or non-tuberculous cases. The characteristic tuberculous reaction is shown by a rise of at least two degrees in temperature, reaching its height in from six to thirty-six hours after the injection, typically at the eighteenth hour, and accompanied by at least two of the following symptoms: chilliness, headache, nausea and muscular pains. The tuberculin test, it is contended, ranks in value with the Widal typhoid test, since in the former the technique is simpler; the

materials are more readily obtained and more permanent; and the danger is no greater, and the information obtained is scarcely less trustworthy.

The Motor Car as a Narcotic.

It has become a stock phrase with journalists to say that "the motor-car has come to stay." It has also become a familiar topic in that form of evanescent literature with which their busy pens are concerned to descant upon locomotion in the future, and to point out how the horse will be abolished, and trade and social habits revolutionised. There is one aspect of the influence of the motor-car, however, that so far appears to have escaped the all-seeing eye of the modern journalist, namely, its action as a soporific. It is a fact well known among those who are in the habit of riding on motors that their sleep is sound and refreshing, even when under ordinary conditions, that is to say, apart from motoring, sleeplessness has been the uncomfortable rule. This result appears to be to a certain extent common to most open-air exercises and pursuits, but the forced respiration connected with the continuous rush through the atmosphere seems to have its own peculiar and specific effect in producing sleep. If this fact be scientifically exact then the therapeutic resources of the medical man will be strengthened by a most practical addition to his curative measures. Instead of prescribing some wretched narcotic drug he will advise a patient to take a motor ride from one place to another within the compass of a day's journey. It is, of course, impossible to gauge the far-reaching consequences of many discoveries, and the fact that he was manufacturing sleep-producing machinery, surely never occurred to the mind of the pioneer in motor cars.

Facilitating Sudden Death.

FROM time to time the medical and lay journals take up the cry of carelessness against licensed and unlicensed vendors of poisons and drugs. Sundry men introduce many-shaped bottles, mostly angular and corrugated, to lessen the risk of accidental poisoning. We have seen the majority of these, and we saw no exception to their general use other than their cost. Less costly and quite as efficacious are the many devices to shift the danger-signal to the cork and its method of being fastened and unfastened. Much less satisfactory are labels; they are blurred, torn, rubbed off, or sometimes they even fall off. Yet in some one, and occasionally in all three ways, the pharmaceutical chemist and the druggist endeavours to protect the public from fatal accidents. We wish we could say as much for the outdoor department of our hospitals; but even there the poison bottle usually has a "caution" label and a "poison" one. But when we come to examine the way in which poisons are dealt out to cottagers, room-keepers, and the poor and illiterate generally by our sanitary authorities, we learn how not to do it. By distributing active poisons, as many of our more powerful disinfectants are, in whisky

and gin bottles to uneducated, thriftless poor, many of whom are intemperate, the authorities are placing death-traps in the dwellings of our unfortunate poor—facilitating sudden death. Better, far better, death by typhoid, with its interval for thought and consideration for the family, than the sudden death of the half-drunken bread-winner who has mistaken the sanitarian's bottle of carbolic acid for what it is labelled—gin.

A New Drug Eruption.

To the many drugs that produce rashes, enumerated by Dr. Prince Morrow in his monograph, may be added arrhenal. On its introduction it was claimed for the new chemical that its use was free from the untoward result of a skin rash. Indeed, the *prima facie* was all in favour of this statement, for the salt was a disodium one, and the sodium salts seldom produce rashes, and when they do they are very slight. This is all the more curious, for all the basic series of less and greater specific gravity are not free from the evil. Every practitioner of medicine has some time or other been chagrined at the drug rash of potassium; the same occurs with lithium, though less frequently, and now it seems that sodium when associated with arsenicum is not free from the unpleasantness. The cacodylates were recognised for more than half a century as having unpleasant properties in more than one direction, not the least of which was a coppery eruption not unlike the copper spots of syphilis. But all this was thought to have been got rid of when the organic radicle was lessened in percentage and the metallic correspondingly increased. This happy delusion is gone. M. Armand Gautier reports a case of arrhenal rash which closely simulated a severe attack of herpes zoster. It is, however, but fair to say that there has been as yet but one case recorded, and it is quite possible that the patient may have had an idiosyncrasy for the drug. Jenny Lind fainted at the smell of roses, and there had to be a special messenger to take her bouquets off the stage and bring them out of the house to prevent her collapsing.

The Nature of Arrow Poisons.

THE chemical investigation of another arrow poison is reported by Professor L. Brieger, who had already fully examined that used by the Wakamba tribe. The poison in this case, used by the Wagogo, is obtained by boiling the branches of the *acconthera absynica*, the native Mshangu. The fruit of this tree is edible, but the stone of the fruit contains the poison. Like the other known arrow poisons, it acts on the heart. The active cardiac constituent proves to be a deliquescent amorphous glucoside. Another arrow poison—of slower action—is obtained from the *Candelaier euphorbis*. The activity of these poisons is said to be suggestive of that of the toxalbumins; but it appears that no antitoxin can be produced. It is worth noting that, although the occurrence of poisoned arrow-wounds was recognised

in classical antiquity, and probably for scores of centuries before, scientific identification was not obtained for any of these toxic agents till towards the close of the nineteenth century. The elder Pliny stated that the ancient Gauls dipped their arrow-points in the juice of the black hellebore, so as to ensure the infliction of a deadly wound. Following the expansion of modern travel and conquest, Hartmann reported the employment of various species of *Euphorbia* for the same purpose by native Africans; Ferreira de Lemos called the attention of the world to the use of curara; and other travellers found that some of the natives of South America utilised in the same way extracts obtained from certain plants of the strychnine family. The natives of the Banks Islands (South Pacific) use extracts of two plants. One of them, *toe*, is a member of the *Euphorbia* family; the other, *loké*, is probably one of the *nux vomica* group. The arrows are sometimes dipped successively in the separate extracts; sometimes, in a mixture of the two. The efficacy of such vegetable arrow-poisons, although received with implicit faith by the ancients, was sharply questioned by some of the more inspired apostles of modern surgery. Ambrose Paré emphatically denied that there was any proof of the efficacy of any arrow-poison; Heister, who examined the evidence at more length, attributed the symptoms which had been described to the nature of the wound itself. Roehard absolutely refused to admit that the arrow-heads used by savages had ever been proved to exercise any toxic agency. Mendam (in 1595), and Barney and Carteret (in 1767), who had special opportunities of making themselves acquainted with such weapons, expressed strong doubts regarding the efficacy of the poisons used. At Gaboon, M.M. Pellaillon and Carville succeeded in demonstrating cardiac paralysis by the action of an arrow-poison. In New Caledonia, a committee formed of Drs. Brassac and Michel, M. Campana, a druggist, and the missionary, M. Montrausier, investigated the native arrow-poison, and found that it produced death by tetanus, but hardly by specific toxic action. Accordingly, the credit of being the first to afford the material for a satisfactory determination of an arrow-poison must rest with the medical hero of the Emin Pasha Relief Expedition, Thomas Heazle Parke.

The Sale of Chloroform.

A DEATH from chloroform under peculiar circumstances was the subject of inquiry at the hands of Dr. Danford Thomas last week, the victim being a married woman, who, it appears, was addicted to inhaling large quantities of the drug. The husband had cautioned several chemists against supplying the deceased with the drug, but she managed to obtain it in spite of him. Under the absurd law regulating the sale of poisons such drugs as chloroform and laudanum can be sold by a chemist to anybody so long as a poison label is affixed to the bottle, but it must be said, to the credit of the average pharmacist, that he is usually very chary of

selling chloroform to lay persons. The fact remains that this woman experienced little difficulty in obtaining pounds of chloroform every week, and ultimately she inhaled sufficient to determine death. It seems idle to hope that Parliament will ever take an intelligent view of the sale of poisons, and the Government have many other matters to occupy their attention without troubling themselves to place a simple and salutary check on the sale of drugs which, in the hands of the public, can have no legitimate use.

Public Vaccinators' Bills.

BOARDS of Guardians all over the country are kicking against the tremendous bills which they are being called upon to pay for the vaccination of the public. Their attitude is somewhat inconsistent, because they have taken great pains to inform the public that the services of the public vaccinator are at the disposal of all and sundry, and then when the bill comes in they profess surprise. We have protested all along against the encroachment of the public vaccinator on the legitimate territory of the general practitioner, for the latter, both as ratepayer and as medical man, is justified in feeling aggrieved at the unblushing house-to-house touting for patients which has characterised the propaganda of the last few months. Of course the bills will have to be paid, but this very fact will no doubt accentuate the indisposition of many boards of guardians to enforce the vaccination laws in their respective districts. When the present law determines next year it behoves the profession in general to insist upon a fuller recognition of their individual rights in this respect as opposed to the privileges of the public vaccinator.

The Annual Dinner of the R.C.S.I.

THE Annual Dinner of the Royal College of Surgeons, which was held on May 12th, was rendered more than usually interesting by the fact that the last medical hero of the Victoria Cross—save one—was present in the person of Surgeon-Captain Crean. We have already related this gallant officer's action, which led to his well-merited reward, and need not again dwell on what is known to all, save to say, in the words of his Excellency the Lord-Lieutenant, who honoured the dinner with his presence, that "it was a story which sent a thrill through their hearts, and which was worthy of the emulation of all young Irishmen." Surgeon-Captain Crean makes the fourth who, holding the diplomas of the Irish College of Surgeons, has been awarded the Victoria Cross. The first to win the distinction was Assistant-Surgeon William Bradshaw, 90th Regiment, who was awarded the Victoria Cross for gallantly defending the wounded left under his charge, when he was himself wounded, Lucknow, Indian Mutiny, 1857; the second was Assistant-Surgeon William Temple, Royal Artillery, who was awarded the Victoria Cross for gallant conduct and devotion in assisting wounded under heavy fire, Maori war, New Zealand, 1864; the third was Surgeon-Major John Crimmin, Indian Medical Ser-

vice, who was awarded the Victoria Cross for attending wounded actually within the enemy's fighting line, and had at one time to leave his charge and fight hand-to-hand against heavy odds, killing one man with his sword; when help arrived the enemy were beaten off, Burma, India, 1889.

Hygienic Aspects of Harris Tweed.

SINCE our first parents discarded "Nature's nakedness" the subject of clothes has assumed world-wide importance. The delights and dangers of garments afford material for endless discussion. Quite recently Harris tweed has been under a ban, and it would seem unjustly so. Dr. Ogilvie Grant, M.O.H. for Inverness, has wisely taken this matter up, and has induced Professor Hunter Steward, of Edinburgh, to submit the condemned cloth to scientific investigation. The outcome of this research seems to show that Harris tweed, as it usually leaves the home of its birth, is free from pathogenic organisms and that those microbes which are present are similar to those found in average country air. The final treatment of the fabric, consisting in prolonged scouring with strong ammonia and subsequent washing and final drying in the sun, is in itself enough to ensure the hygienic qualities of the goods. It would seem therefore that peat reek may still be allowed to scent our tweeds and that the familiar "Harris" is not to be allowed to gather (with the crowd of "offcasts."

A Study of Ancestors.

ANCESTORS have much to answer for, Pathologically speaking, this is certainly true, as every medical man knows only too well. The investigation of the influence of family inheritance has to be considered carefully in many diseases. But medical practitioners, especially those who retain something of the spirit of the old-fashioned country doctor, friend of the squire, and confidant of the parson, are interested in genealogical studies, family history and heraldry, as affording some of the most attractive and instructive hobbies connected with human affairs. To such we cordially recommend the new quarterly issued by Messrs. Archibald, Constable & Co., and most appropriately termed *The Ancestor*.

Bathing for Women.

THE County Council are wise in encouraging aquatic instincts in women. Accommodation for female bathing in the parks is at present meagre in the extreme, but by a little careful organisation increased opportunities might readily be afforded. The climate of this country during a great part of the year is not such as to stimulate bathing, but during the summer months every facility should be afforded whereby our girls and young women might learn to swim. An additional influence making for health and vigorous physical development would thereby be obtained which would prove of benefit to the whole community.

WE regret to have to announce the death of Dr. J.

Miller Ord, of Upper Brook Street, W., which took place last week. We shall deal with his career next week.

PERSONAL.

MR. THOMAS JOSEPH STAFFORD, F.R.C.S., Ireland, has been appointed a member of the Royal Commission on Sewage Disposal.

THE Right Hon. H. H. Asquith will take the chair at the Festival Dinner of the Medical Graduates' College and Polyclinic on June 5th.

DR. STEPHEN MACKENZIE will deliver the Oration which precedes the Annual *Conversazione* of the Medical Society of London, on Monday, the 26th inst.

THE Very Reverend Dr. Story, Principal of the University of Glasgow, has promised to preside at the dinner to be given by the Glasgow University Club on July 1st.

DR. ROBERT FARNAN has been selected to fill the post of Gynaecologist to the Mater Misericordiae Hospital, Dublin, which was rendered vacant by the death of Dr. More Madden.

SIR FREDERICK TREVES will deliver the Cavendish Lecture before the West London Medico-Chirurgical Society on Friday, June 20th, on "Certain Phases of Appendicitis."

PROFESSOR J. ROSE BRADFORD will deliver an address on "The Relation of Biology to Medicine" at a meeting of the University Hospital Medical Society to-day.

DR. T. HENRY GREEN will deliver the opening lecture of the Summer Course at the Brompton Hospital for Consumption to-day on "Difficulties in the Recognition of Pulmonary Tuberculosis."

MRS. H. PERCY DUNN, F.R.C.S., will take the chair at the Dinner of Past and Present Students and Officials of the West London Hospital Post-Graduate College, which will take place on June 11th at the Trocadero Restaurant.

Belfast.

[FROM OUR OWN CORRESPONDENT.]

ROYAL UNIVERSITY EXAMINATIONS.

THE results of the spring examinations of the Royal University have proved very satisfactory to Belfast, especially in the case of the M.B. degree examination, where Mr. Walter Phillips, B.A., Queen's College, Belfast, has gained a first-class exhibition, and Mr. John Armstrong, also of Queen's College, Belfast, has gained a second-class exhibition.

One unobtrusive little paragraph in the report of the Royal University Senate meeting of the 15th was observed with great satisfaction by those who have been following the doings (and undoings) of that august body in the matter of extern examinerships. It was currently reported the week before last that the Medical Committee had nominated five extern examiners, all from Dublin and Cork, and that Belfast had been left out in the cold. Hence the satisfaction of those here who read, in the paragraph above referred to, that "the report of the Medical Committee in reference to the appointment of extern examiners was referred back for further consideration."

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE USE AND ABUSE OF TOBACCO.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have long believed in tobacco smoke as having germicidal properties. An observant young woman told me not long ago how her father, who was an undertaker, believed that he escaped contagion from corpses by smoking. He and two others placed in a coffin the body of one who had died of small-pox. The two non-smokers caught the malady, while the smoker escaped.

A man who was in a house where all were down with influenza told me he thought his own immunity was due to the constant use of his pipe. Those stricken with disease were non-smokers.

I am sure much valuable information might be gathered from the experience of smokers.

One of my smoking friends, troubled with a sluggish liver, was telling me of the benefit he derived from taking the Harrogate waters. One thing that struck him was the fact that while his health mended he felt less desire to smoke. There seems some nervous irritation of the system, however caused, that is undoubtedly relieved for a time by smoking. Cure the irritation, and the patient may tell you he feels so well that he eats and drinks better than before, and cares not to smoke.

I am, Sir, yours truly,

JOHN C. THOROWGOOD, M.D., F.R.C.P.
Bognor, May, 1902.

PATIENTS' RECORDS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have on several occasions, when called to a new patient, found myself at a loss in the matter of diagnosis simply because the patient had at some time in the past been subjected to an abdominal operation, the nature and scope of which he, or she, has been quite unable to explain. The required information could, it is true, be obtained by writing to the surgeon who had performed the operation and I have never had any difficulty on this score, provided that the patient was able to remember his name. But this is often not the case or the surgeon may be dead or have retired and in either event I was deprived of information very essential to a clear understanding of the case. It occurs to me that it would be a very easy matter for a short, simple statement of what has been done, and the reasons for which it was done, to be handed to every patient on leaving hospital. The labour entailed would be small, and the scientific and practical value of such reports would be great.

It is hardly necessary to point out that no verbal explanation can be trusted to answer the purpose even with educated people, the difference between the tale as it is told to them, and the tale as it is retailed by them, being often remarkable.

I am, sir, yours truly,

COUNTRY PHYSICIAN.

NATALITY IN GREAT BRITAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Among several interesting letters which have appeared under the above heading in your columns, I have had my attention especially caught by two. One by "A Student of Medicine" and another by a "Gynaecologist." The Student of Medicine takes the obviously proper and respectable view of the moral aspect of the limitation of families—a view which I entirely endorse, and enquires from the Gynaecologist what he thinks of the physical aspect of the question. Has the use of means of preventing conception any effect on the physical health of the woman? There can be no question that the adoption of certain methods of preventing conception will favour the occurrence of certain forms of pelvic derangements, but there is nothing to lead us to suppose that the fact that impregnation does not follow coitus has any detrimental effect. Women and

their sexual organs have a certain function attached to them. If this function is not performed the result, so far as we can see, is that the woman suffers, and, as the "Gynaecologist" puts it, a fibromyoma may be "Nature's protest against the disappointed natural function of the uterus." But it is, at least, extremely doubtful that the married woman who does not conceive, suffers more than does the unmarried woman. In all probability they each suffer in consequence of their sterility and in proportion to other and more personal factors. On the other hand, they are exempt from various pathological conditions which are peculiar to women who have borne children. It may be said that if sterility favours pelvic derangements, and if the use of preventatives causes sterility, then the use of preventatives favours pelvic derangements. This is not so. It is the sterile condition which causes derangements and not the fact that coitus has occurred without impregnation. It is good for every woman to become pregnant and to bear children, but if in the case of a woman who has borne children medical reasons necessitate that she should not bear any more, I cannot believe that the use of preventatives in such cases have any more hurtful effect than has abstention from sexual intercourse.

I am, Sir, yours truly,

X.

Literature.

RECENT WORKS ON CONSUMPTION. (a)

(1) As a short summary of work done by the Conference on Tuberculosis held in London in 1901 this work is one that will amply repay the careful reader. Dr. J. H. Vinrace, in his preface, most sensibly remarks that there is no reason whatever now why the consumptive patient should be expatriated and sent abroad when he can undergo a most perfect system of sanatorium open-air treatment in the equable climate of the south coast of England.

The chapter on the use of drugs in the cure of consumption will commend itself to hospital physicians whose patients are of necessity so much dependent on what help they may get from drug treatment. Facts as at present recorded bearing on the relation between human and bovine tuberculosis are well summed up in Chapter xviii. We leave the reader to draw his own inference from them. The observations of Dr. Hugh Walsham and others on the diagnosis of very early tuberculosis of the lungs by means of the Röntgen rays are well condensed, and evidently of great practical importance both for diagnostic and therapeutic purposes.

Though the book is not large, yet the writers manage to give a short note of every matter of consequence that came before the late Congress, so that anyone wanting to be quickly posted up in recent researches on tuberculosis, its causes and prevention, will find this a most useful work.

(2) This book might be entitled the management of the consumptive on common sense principles.

It gives, as stated in the preface, rules to govern the consumptive in the use of fresh air, sunlight, food, rest and exercise. All to be carried out under the supervision of the physician. The book is one that may with safety and advantage be placed in the hands of the invalid, for in it he will find much to instruct and encourage, while dangers are judiciously pointed out. The subject of infection is briefly disposed of in Chapter II. The way to guard against the spread of the disease by means of the sputa and other channels is clearly indicated. The chapter on food is agreeable reading and rests on the statement that the way to the lungs for beneficial result is through the stomach. We are

(a) (1) "The War against Consumption." By Dennis Vinrace, M.R.C.S., L.S.A., and John H. Vinrace, M.R., M.R.C.P.Lond, The Century Printing Company.

(2) "The Care of the Consumptives, with Chapter on Colorado." By C. F. Gardiner, M.D. New York: G. E. Putnam's Sons.

(3) "Tendencies to Consumption." By J. D. E. Mortimer, M.B., F.R.C.S.Eng. London: The Scientific Press.

(4) "Pulmonary Tuberculosis, with Appendix concerning the British Congress on Tuberculosis." By Carlo Eusta, M.D., of Perugia. Bristol: John Wright and Co. London: Simpkin and Marshall.

glad to find the author firmly discouraging the use of sedative and sickly cough medicines. The full account of the open-air and food-stuffing treatment as carried on at Nordrach, in the Black Forest, is taken from the work on the "Treatment of Pulmonary Consumption" by Harris and Beale. The treatment is evidently thorough, and no half-and-half work. After reading it, however, we could not but think of the story of the physician who, after laying down most strict rules for diet, &c., to a rather gay young man, was met by the inquiry, "Pray, Doctor, do you live according to these rules?" "No, sir," was the answer, "life to me under such conditions would not be worth living." The chapter on the Psychology of the sick room is one that ought to be read and studied by all who have the care of the sick.

The chapter on Colorado from one who has had sixteen years' practice there is very valuable. Some of the most remarkable cures of advanced phthisis that we have ever witnessed have been brought about by the dry and elevated climate of Colorado and Denver City. For a short concise account of the climate, and the way to make the best of it for curative purposes nothing can be better than this eleventh chapter of Dr. Gardiner's book. The eleven "Dont's" that conclude the book are not likely to be missed by the intelligent reader.

(3) This small work has been prepared as a contribution to the prevention of consumption. Recent research has done much to elucidate the causes of tuberculous disease in the lung, and to show in what direction preventive measures should go. The author of this book gives a brief but lucid description of the bacillus of tubercle which may be well studied by all who have entered on the subject. The remaining chapters show how the disease may be engendered by faulty methods of life and by pernicious surroundings. The methods of prevention by the use of various hygienic and dietetic precautions are given in a practical form that will make the book useful to all who may study it.

(4) The author of this carefully compiled and interesting book may certainly hope, as he says in his preface, that whoever reads these pages will not regret the hours spent in their perusal. The early chapters give a brief and concise resume of our present knowledge with regard to the mode of development and pathological changes undergone by tubercle, the right understanding of these matters being aided by the well-executed illustrations which adorn this part of the volume. It is rather disquieting to read, at page 24, "That those who live in or visit the house of a consumptive patient breathe tuberculous bacilli in abundance." This statement, like most others in the book, is not made as a mere opinion, but is substantiated by the experiments of Professor Strauss in the Hospital of La Charité in Paris by means of collecting tubercle bacilli on small pledgets of wool placed in the nasal cavities of the hospital attendants.

Having had the dangers of the disease duly pointed out, we naturally turn to Chapter IX., on Treatment. Remedies given by the mouth do not find much favour. Creosote, now so largely employed in big doses, enters the alveoli very little, and is finally eliminated by the urine, and thus, carried to distant organs, produces serious mischief. (P. 101.) The author's reasons which compel him to admit the influence of heredity are based upon a table of statistics at page 59, which we commend to the attention of all interested in this part of the subject. The history of the open-air treatment so extravagantly lauded just now is well given. It commences with the account of Dr. George Bodington's Sanatorium at Sutton Coldfield in 1830, a method of treatment at that time denounced most vigorously by "the Faculty," who set Dr. B. down as a lunatic.

Now in Germany there appear to be thirty-three popular sanatoria, while in the British Isles the number increases almost daily. That much good is being done in these establishments is amply proved, and when the present enthusiasm in this subject has somewhat subsided we doubt not that there will be a large number of real cures effected. The chapters on continuous inhalation by respiration, which is a very prominent feature

in the author's method of treatment, are thoroughly practical and based on the pathological views set forth in the earlier parts of the work. As a book of careful observation and sound reasoning from observed facts it is one to be much commended.

ORR ON PUBLIC HEALTH. (a)

THE writer has, we fear, attempted the impossible by endeavouring to condense into the small space of 236 pages of largely printed matter even that small amount of hygiene and the allied subjects which is considered essential for the modern medical student to be familiar with. The result has been of necessity more or less of a failure, and has resulted in the omission of some important parts of the subject and the insertion of others under wrong headings; for instance, the author omits any chapter on Meteorology, but deals with the subject in a casual fashion partly under "Air" and partly under "Climate." The author, we observe, finds some apparent difficulty in accepting the result of recent research with regard to the mode of dissemination of malaria, as on page 8 he still clings to the old idea of the so-called "miasm" rising with the ground air. There are many faults in the book which might with more care have been avoided. For example, the mode of calculating a weekly death-rate is inaccurately given, and surely if such knowledge be essential for the student he may as well be taught it correctly. Apart from its inherent faults, the book is pleasantly written, though we do not think it will take the place of the well-known handbooks on the subject which are already within reach of the medical student.

Literary Notes and Gossip.

DR. CLAUD MUIRHEAD and the Scottish Widows Life Assurance Society have done well in issuing their valuable report on "The Causes of Death" among those assured in this well-known Society. It is to be hoped that the example thus set will be speedily followed by other insurance offices. Nothing but good can come from the publication of such mortality experience for the guidance of all interested in life assurance.

MR. F. D. HOW has written for Messrs. Isbister and Co. a memoir of the late Dr. William Smyth (2s. 6d. net), "A Medical Hero," the story of whose noble self-sacrifice, even to the laying down of his life, in the cause of duty, while fighting an outbreak of typhus on the poverty stricken island of Arranmore, so thrilled the hearts of readers when first made public in our columns last autumn.

CANON ELLACOMBE, in his charming little work, "In my Vicarage Garden and Elsewhere," has an interesting chapter on "The Medical Properties of Flowers," which we venture to think will be particularly pleasing to some of our country practitioners.

DR. MARGARET TODD, better known as "Graham Travers," who made for herself a name and a place in the world of fiction by her novel "Mona Maclean," which was of considerable medical interest, has just published another work, which we understand furnishes ample evidence of the author's intimate knowledge of character and the vicissitudes of our mundane existence, in which her acquaintance with medical affairs is abundantly apparent.

IN the interesting life of William Black, by Wemyss Reid, recently published, there are some interesting letters which show the great novelist's appreciation of his medical advisers. The page labelled "The Vagus Nerve" will be read with interest by not a few friends of a well-known medical romancer.

THE sixth annual Medical, Surgical, and Hygienic Exhibition will be held at the Queen's Hall on May 20th—23rd.

(a) "Handbook of Public Health." By John Orr, F.R.C.P.E., M.B.C.S. Eng. Pp. 236. Edinburgh: D. S. Livingstone. 1902.

Medical News.

Handsome Gift to the Dundee Royal Infirmary.

Mr. J. K. CAIRD, Dundee, has offered the Dundee Royal Infirmary a much needed addition to its resources in the shape of a separate block of buildings, part of which will be for patients suffering from cancer, while the remainder will be utilised for affording a much-needed relief to the present overcrowded state of the hospital. The estimated cost of the building is £18,500.

Mr. Caird further offers £1,000 per annum for five years for research in cancer.

Medical Sickness and Accident Society.

THE nineteenth annual report of the above Society has just been posted to the members, and shows that the business is growing in size and financial strength. During the year 1901 the funds increased by £10,801 6s. amounting on December 31st last to £154,353 17s. 3d. The greater part of the increase is due to the growth of the reserves in the sickness branch of the Society, for no new annuity nor life assurance business has been transacted for many years. The principal object of the Society is to make provision for medical men when disabled either by sickness or by accident. The business was started in 1884, and so carefully was it founded that although it was at first necessarily somewhat of an experiment the contributions of the members have always sufficed to pay the claims which have been experienced, and in no one year of its working has the Medical, Sickness, and Accident Society paid away more sickness claim allowance than was expected and provided for in the contributions. During its eighteen years of working no less than £75,000 has been paid by the Society to its members in the shape of weekly allowances, and the committee are constantly receiving evidence of the great value these allowances are to the recipients. The Society has been always entirely self-supporting. The committee of management have given their services free of cost, and in this and other ways have enabled the business to be worked in a very economical manner. So far less than 5 per cent. of the premium income has been sufficient to cover the whole expenses of management, and although, in addition to the large sums paid in claims, cash bonuses amounting to more than £10,000 have been returned to the members the large amount of over £150,000 has been accumulated. The committee have been specially anxious to accumulate a large reserve in order that they may safely carry out one of the most valuable objects of the Society, viz., the granting of what is practically a permanent provision to those members who become permanently disabled. More than a dozen members are now in receipt of an annuity, usually one hundred guineas a year, and the value of this provision to a man who can never hope to resume professional work can scarcely be over-estimated. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical, Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Royal Medical Benevolent Fund Society.

ON Thursday afternoon, the 15th inst., the annual meeting of the Belfast branch of this fund was held in the Museum, College Square North. Professor Whitla, President, occupied the chair. After the adoption of the minutes, Dr. Purdon submitted the secretary's and treasurer's reports, which were considered most satisfactory. The President moved the adoption of the reports. In doing so, he said they had heard satisfactory reports. When last they met they had to face a fund which had fallen to somewhere between £80 and £70 a year. A special effort, however, brought it to £200. He felt it was a comparatively easy thing for the fund to be raised by one spasmodic effort from £60 or £70 a year to £200, but the question was could they keep it at that? There was only one matter for regret. He understood that fifty-two members of the profession refused to give any subscription, and there were twenty-five who gave practically no subscription. He had great pleasure in moving the adoption of the reports. Dr. Whitaker seconded the motion, which was

unanimously adopted. Professor Lindsay moved the re-election of the President, which was agreed to, amid hearty applause. On the motion of Colonel Dr. M'Farland, seconded by Dr. Boyd, the Committee was elected as follows:—The President, Hon. Treasurer, Dr. Purdon, Professor Lindsay, Drs. Brice Smith, W. A. M'Keown, H. O'Neill, J. M'Caw, M'Arthur (Greyabbey), Sinclair Boyd, Leslie, Gibson, Whitaker, Dempsey, R.C. M'Cullough, St. George (Lisburn), Darnell (Bangor), Donnan (Holywood), M'Kisack, and Mr. J. C. C. Payne, J.P. Dr. Purdon was appointed hon. secretary and hon. treasurer. The proceedings then concluded.

Medical Golf Tournament.

THE fifth annual tournament will be held on the 29th inst. at Northwood (by kind permission of the Northwood Golf Club). Regulations as for 1901. 18 Holes Match, Play v. Bogey; foursome sweepstakes during afternoon. Two classes (1) handicaps of twelve and under, (2) over twelve, members of Northwood deduct two from their handicap. 1st and 2nd prize and prize for best last nine holes v. Bogey in each class. No match may be started later than 3.15 p.m. No previous play allowed on the day. Entries, stating lowest handicap and enclosing 5s. entry fee, should be made before the 26th inst. to the hon. sec., Rolf Creasy, Windlesham, Surrey.

Dublin Death-rate.

The deaths registered in the Dublin Registration area for the week ending Saturday, May 10th, 1902, represent an annual rate of mortality of 23·8 in every 1,000. Diseases of the nervous system caused 18 deaths, of the respiratory system 29 deaths, and of the circulatory system 19 deaths; 52 infants died during the week, of whom 37 were under one year old. In 12 instances the cause of death was "uncertified," there having been no medical attendant in the last illness. In the Grand Canal Street district the death-rate was 32·9, in Somerset Hill district 29·3, in Lisburn Street district 26·0, and in South Earl Street district 26·6.

Pass Lists.

The Royal University of Ireland.

The results of the Spring Medical Examinations were presented and approved, and the following Exhibitions were awarded:—

Second Examination in Medicine.—O'Connell Sullivan, Second Class Exhibit, £15.

Third Examination in Medicine.—William M. Crofton, B.A., First Class Exhibit, £30; Denis J. Keane, Second Class Exhibit, £20.

M.B., B.Ch., B.A.O. Degrees Examination.—Walter Phillips, B.A., First Class Exhibit, £40; John Armstrong, Second Class Exhibit, £25.

The report of the Medical Committee in reference to the appointment of Extern Examiners was referred back for further consideration.

A meeting of the University was subsequently held, when the following degrees were conferred:—

M.D.—E. H. Grills, H. J. Monypenny, Isabel A. Tate.

M.Ch.—E. S. Ryce, B.A., M.D.

M.B., B.Ch., B.A.O.—W. Phillips, B.A.; John Armstrong, A. L. Black, S. E. Hunter, C. F. White, D. R. Campbell, B.A.; John Clements, B.A.; A. W. Hamilton, J. P. Higgins, M.A.; J. L. Lunham, M. J. Macauley, F. H. M'Caughy, E. J. M'Kenna, F. C. Mann, L. T. Moore, W. F. O'Connor, Patrick O'Doherty, John J. Hare, F. W. Stewart, B.A.; William A. Stoops, B.A.; W. J. Thompson.

Scotch Qualification in Public Health.

AT the half-yearly meeting of the Conjoint Board of Examiners in Public Health of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, held in Glasgow, the following medical practitioners, having passed the necessary examinations, were admitted Diplomates in Public Health:—Peter Aitken, Gilbert Edward Brooke, Walter F. Brown, Duncan Fletcher, James Livingston London, Neil Macvicar, William Russell, Alexander Watt, Frank Mayes Willcox.

THE WAR AND THE BIRTH-RATE.

At the last meeting of the Normanton Urban District Council the medical officer's report caused a good deal of amusement and comment. It stated that the birth-rate for the district had been very low for many years, but since the war it had risen, and the medical officer expected the higher rate would be maintained as long as the war continued, at which conclusion the members laughed heartily.

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, MAY 21ST.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.)—7.30 p.m.

UNIVERSITY OF LONDON PHYSIOLOGICAL LABORATORIES (South Kensington).—5 p.m. Dr. Leonard Hill: The Physiology of Respiration.

THURSDAY, MAY 22ND.

NEUROLOGICAL SOCIETY OF LONDON (11, Chandos Street).—8.30 p.m. (patients at the rooms at 8 p.m.).—Clinical evening. Cases will be shown by Mr. Richardson Cross, Dr. Parkes Weber, Dr. Farquhar Buzzard, Dr. Colman, and others.

HARVEIAN SOCIETY OF LONDON (Stamford Rooms, Edgware Road, W.).—8.30 p.m. Cases will be shown by Mr. Watson Cheyne, Dr. A. Whitfield, Dr. A. Morison, Mr. F. Jaffrey, and others.

FRIDAY, MAY 23RD.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Annual general meeting; election of officers for session 1902-1903. The following papers will be read:—Sir Thomas Barlow and Dr. H. Batty Shaw: Inheritance of Recurrent Attacks of Jaundice and of Abdominal Crises with Hepato-spleno-megaly. (Two cases will be shown.) Dr. W. Hale-White and Mr. C. H. Golding-Bird: On the Subsequent History of Three Cases of Colitis on whom Right Lumbar Colotomy was performed several years ago.

POST-GRADUATE COURSES AND LECTURES (Medical Graduates' College and Polyclinic, 22, Chenies Street, W.C.).—Demonstrations will be given at 4 p.m. as follows:—Monday, Skin; Tuesday, Medical; Wednesday, Surgical; Thursday, Surgical; Friday, Throat.

MONDAY, MAY 20TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 p.m. Communications will be given by Mr. J. Sefton Sewill: A Case of Fractured Tooth; Mr. Kenneth W. Goodby: Sterilisation of Impression Composition. A Paper will be read by Mr. J. H. Targett: Some Growths about the Jaws.

DUBLIN.

THURSDAY, MAY 22ND.

ROYAL COLLEGE OF SURGEONS.—Council Meeting.

FRIDAY, MAY 23RD.

ROYAL ACADEMY OF MEDICINE IN IRELAND—Section of Obstetrics.—College of Physicians, 8.30 p.m. Specimens:—Dr. Alfred Smith: Tuberculous Erysipelas (four specimens). Dr. Horn: Fibroid Uterus Removed by Panhysterectomy. Papers:—Dr. E. H. Tweedy: Observations on the First Stage of Labour; the Causal Relation of this Stage to Rupture of the Uterus. Dr. John Knott: A Case of Amenorrhoea. Dr. Purfoy: Report of the Gynaecological Department of the Rotunda Hospital for the year 1900-01. Drs. Neill and McWeeney: A Case of Puerperal Eclampsia.

Appointments.

BELL, K. de R., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory Act for the Uppingham District of Rutland.

BLACK, A. L., House Surgeon to the Royal Victoria Hospital, Belfast.

COOMBS, HOWLAND HILL, M.D. Durh., Medical Officer for the Rural District of Bedford.

CROW, J., M.B., Ch.B. Glasg., Medical Officer and Public Vaccinator for the Largs and Fairlie Districts Parish Council.

DALY, F. J. F., M.R.C.S., L.R.C.P., Medical Officer to No. 10 District of the Hackney Union.

GLENNY, EDMUND, L.R.C.P.I., L.R.C.S.I., Senior House Surgeon to Jervis Street Hospital, Dublin.

GRACE, A. H., L.S.A., Certifying Surgeon under the Factory Act for the Chipping Sodbury District of Gloucestershire.

JONES, O. C., M.B. Oxon., Certifying Surgeon under the Factory Act for the Ilfracombe District of Devon.

MILNER, ERNEST ARTHUR, M.B., C.M. Edin., Medical Officer of Health for Lostwithiel (Cornwall).

RICHARDS, E. W., M.D. Lond., Certifying Surgeon under the Factory Act for the Dolgelly District of the County of Merioneth.

RICHARDSON, W. P., M.B., M.S. Edin., Certifying Surgeon under the Factory Act for the Blisworth District of Northamptonshire.

RYAN, JOHN P., L.R.C.P.I., L.R.C.S.I., Junior House Surgeon to Jervis Street Hospital, Dublin.

SHAW, JAMES, M.D. Glasg., Certifying Surgeon under the Factory Act for the Aylesbury District of Bucks.

STEVENSON, HOWARD, M.B., B.Ch., B.A.O.R.U.I., House Surgeon to the Royal Victoria Hospital, Belfast.

TYNDALL, FRANCIS, M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory Act for the Westhoughton District of Lancashire.

Vacancies.

Clogher Union.—Medical Officer. Salary £100 per annum, with Registration and Vaccination Fees. Also a Medical Officer of Health. Salary £15 a year. Applications to Thomas Turner, Clerk of Union. (See Advt.)

Down County Infirmary.—House Surgeon. Salary £80 per annum. Applications to Dr. Tate, Downpatrick (See Advt.)

Durham County Asylum.—Third Assistant Medical Officer. Salary £150, with apartments, board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Hereford County and City Asylum.—Senior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Also a Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Lancashire County Asylum, Warrington.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications immediately to the Medical Superintendent.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £180 per annum. Furnished apartments, attendance, light, and fuel are found. Applications to Secretary, Journal Chambers, Nottingham.

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £110 per annum, with board and lodgings. Applications to Chas. W. Dickinson, Capt. R.N., Secretary.

Royal Cornwall Infirmary.—House Surgeon. Salary £100, with board, and apartments. Applications to the Secretary, 4, Parkview Terrace, Truro.

Sir Patrick's Dun's Hospital.—Lady Superintendent. Salary £125 per annum, with furnished apartments, laundry, and attendance. Applications to the Secretary of Medical Board. (See Advt.)

Suffolk General Hospital.—House Surgeon. Salary £100 a year, with board, lodging, and washing. Applications to Henry Bonner, Secretary, Bury St. Edmunds.

The Westmorland Lock Government Hospital.—Resident Medical Officer. Salary at the rate of £100 per annum, with furnished apartments, &c. Applications to the Registrar, Dublin. (See Advt.)

Traveller.—London firm of manufacturing druggists invites applications from medical men willing to represent them in India, the Colonies, and the Continent. For further particulars see Advt.

Wolverhampton and Staffordshire General Hospital.—House Physician.—Salary £100 per annum, with board, lodging, and washing. Applications to Edmund Forster, House Governor and Secretary.

Births.

ALDERSON.—On May 16th, at 5, Eldon Square, Newcastle-on-Tyne, the wife of Wilfred E. Alderson, M.D., M.B., of a son.

BUTHERFORD.—On May 13th, at 12, Newton Place, Glasgow, the wife of Henry Butherford, M.B., of a son.

Deaths.

BODINGTON.—On Thursday, May 8th, at Hotel d'Jena, Paris, George Fowler Bodington, M.D. Durh., aged 73.

ORD.—On May 14th, at the residence of his son, The Hall, Salisbury, William Miller Ord, M.D., F.R.C.P., Consulting Physician to St. Thomas's Hospital, London, aged 67.

PITT.—On May 17th, at Wellesbourne, Richard Pitt, M.R.C.S., L.S.A., in his 85th year.

WHITMORE.—On May 18th, William Tickle Whitmore, F.R.C.S., of 18, Vernon Terrace, Brighton, formerly of 7, Arlington Street, Piccadilly, London.

Original Communications.

ON THE SUBSEQUENT HISTORY OF THREE CASES OF COLITIS, ON WHOM RIGHT LUMBAR COLOTOMY WAS PERFORMED SEVERAL YEARS AGO. (a)

By W. HALE WHITE and C. H.
GOLDING-BIRD.

It may be within the memory of some members of this Society that on May 12th, 1899, we read a paper here on three additional cases of right colotomy for chronic colitis. This evening we propose to give the subsequent history of each of these cases, the early details of which will be found in our previous paper.

CASE I.—Miss F., *æt.* 36, had suffered very severely from membranous colitis for twenty years. On May 13th, 1896, the first stage of right lumbar colotomy was performed, the bowel being opened six days later. In May, 1897, a year from the operation, we closed the artificial anus without difficulty. During this year, from May, 1896, to May, 1897, her general health had considerably improved, and she had gained flesh. Her doctor, Dr. A. E. Taylor, of Lancaster Gate, wrote on August 4th, 1896:—"She has done very well indeed; not had a bad symptom; very few casts; she is now up and about, and is getting stout." After May, 1897, the date of closure, our first report is November, 1898, when she came to see us; she then looked perfectly well, was living an ordinary home life, was active in her habits, and taking moderate outdoor exercise, but had to take aperients to get the bowels open. From November, 1898, we heard nothing of Miss F. till we wrote to her in February, 1902. She was then in bed with rheumatic fever, so her mother wrote saying as follows:—"She has to admit that there is very little change in her condition (compared with that before operation), and she could not candidly say there is a perfect cure." It is clear from this report that she has relapsed from her improved condition in November, 1898. Her mother continues her letter saying:—"The general health is very bad; occasionally swelling attacks (tyimpanites); great wasting of the body; the food passes through undigested, accompanied by casts and blood occasionally. There is considerable constipation."

Dr. A. E. Taylor corroborates this written account, and he adds that she has recently had two attacks of sub-acute rheumatism. We wrote to the patient's mother to say when the relapse began, and she replied that it was in December, 1898.

(a) Paper read at meeting of Clinical Society, May 23rd, 1902.

CASE II.—Laura B., *æt.* 31, a barmaid, had suffered from symptoms of severe colitis for eighteen months, passing much membrane. On March 3rd, 1898, the first stage of right lumbar colotomy was performed, the bowel being opened on March 8th. The artificial anus was closed without difficulty on September 29th, 1900, two and a half years after it was made. During this two and a half years, in which the wound remained open, the patient remained in perfect health, resuming her business as a barmaid six months after the artificial anus was made, and subsequently continuing her occupation without interruption. She suffered no inconvenience from the protective apparatus she wore over the opening, and, indeed, twice refused our offer to close the artificial anus as she had got quite used to it, and was afraid of running the risk of return of the membranous colitis. During the eighteen months that have now elapsed since the closure of the wound she has remained in perfect health, following her usual occupation. There has been no trace of membranous colitis, and to assure ourselves, last November we took her into the hospital for a short time and examined all the motions. They were perfectly natural. She remains well at the present time.

CASE III.—Edward K., *æt.* 35, had suffered from symptoms of chronic colitis for seven years. Colotomy was performed December, 1898. Five days later the bowel was opened, and seven weeks later he left the hospital to return to work, much improved in his general health and having lost all his symptoms of colitis. During the summer of 1899 he worked hard as an artisan in Woolwich Arsenal, and as he continued perfectly well was anxious for an early closure of the wound. Two attempts were therefore made during this year (1899), but neither were successful, though the opening was much reduced in size. Since the second of these attempts very nearly all the faeces have passed naturally through the colon and per rectum in a perfectly healthy way, only a little occasionally coming through the colotomy wound. A third and last attempt was made in 1901, but again with only partial success. But on February 25th, 1902, he presented himself in good health and reported that the small sinus resulting from the last operation had closed by itself. It will be noticed that he has remained well for two and a-half years after the passage of faeces along the colon has been re-established.

We think these records show that in severe cases of chronic colitis which have not yielded to other treatment right-sided colotomy is beneficial. Indeed, in each of these three cases it was curative; for Miss F. did not relapse until eighteen months after her wound was closed, and the other two patients, although their colotomy wounds are closed, remain perfectly well. The difficult question that has to be determined is how long shall the artificial anus be kept open, and whether in certain cases it should

ever be closed at all. It is to be noticed that in Miss F.'s case the artificial anus was closed at the end of twelve months, during which period she had remained free from her symptoms, as indeed she did for several months after the closure, but eventually she relapsed. With our present experience the extreme duration (twenty years) and great severity of the disease in Miss F., who had become a thorough chronic invalid, would lead us to suggest, if we saw another patient like her, that the artificial anus should be maintained considerably more than a year; and though in our second case the artificial anus was kept open two and a-half years at the patient's own request, it is likely that by this request she did herself a great service, for had we closed the wound earlier she might have relapsed; still, the duration of her disease was short. These two women are instances of *membranous colitis*; the third case, a man, was one of chronic dysentery; he so immediately improved after colotomy that we made the first attempt to close his opening in a few months, and we felt warranted in the attempt because, owing to the mechanical difficulties of plugging the wound in his cæcum, there were frequent escapes of faeces into the colon, although the passage of these was not sufficient to provoke any return of his symptoms. The difficulty in restraining the escape of the intestinal contents along the colon on the one hand, and externally on the other, because of its fluidity, compels us to form an adverse opinion of cæcotomy in these cases, as compared with a right lumbar colotomy; and for the same reason also a cæcotomy wound is more difficult to close.

To avoid the nuisance of an artificial anus a small valvular opening in the colon has been suggested and employed. ("Transactions" of New York Surgical Society, January 23rd, 1901, communication by Dr. Percy Bolton.) Through it antiseptic irrigation from it to the anus has been practised, but our opinion is that in membranous colitis irrigation does more harm than good; the complete rest given to the colon by the artificial anus is all that is required. Our reasons for this view are given in our former communication.

It has been suggested to us that the implantation of the ileum into the sigmoid would meet all requirements without an artificial anus, and ensure permanency of cure. Three objections at once present themselves to this plan. In the first place the irritating fluid contents of the ileum passing at once into the rectum would be likely to produce a chronic diarrhoea; secondly, some of the contents of the small intestine would be sure to regurgitate from the sigmoid flexure into the colon and so keep up the colitis; and, thirdly, the implantation would in many instances not be above the whole of the disease.

INHERITANCE OF RECURRENT ATTACKS

OF

JAUNDICE AND OF ABDOMINAL CRISIS

WITH

HEPATO-SPLENOMEGALY. (a)

By SIR THOMAS BARLOW, BART., and
H. BATTY SHAW, M.D.

ABSTRACT.

THE observations giving rise to this paper were made upon two patients, Albert W., æt. 19½, and Mrs. W., his mother, æt. 47.

Albert W., when born, was noticed to be a very delicate child, and was pale and waxy-looking. At

five years of age he was noticed to be jaundiced for the first time, and since then there have been attacks of semi-jaundice lasting three or four days, accompanied by pain in the upper part of the abdomen. For the last six years he has been troubled with indolent ulcers about the ankles which only healed when he kept in bed for some days.

On admission to University College Hospital in 1899, the patient was found to be undersized for his age, and looked anæmic and yellow. The liver was only moderately enlarged, but the spleen was much enlarged, reaching two inches below the level of the umbilicus; there were signs of cardiac dilatation more particularly of the left ventricle; the stools were repeatedly examined and were always found to be brown in colour, the urine very often was high coloured, no bile could be demonstrated, but urobilin was easily detected spectroscopically without extraction. Examination of the blood showed signs of there being present some secondary anæmia. The temperature rose a little, but was never more than 99.6° F.

The boy was again admitted in May, 1901, there was practically no change in the size of the spleen, but a slight reduction of the liver dulness below the right costal margin. A few glands were noticed in the neck. Besides a reduction in the number of red corpuscles of the blood and of the hæmoglobin, poikilocytosis, nucleated red corpuscles and basophile cells were met with, and during the earlier part of his stay in the hospital, the leucocytes numbered 14,000 per cubic millimetre. None of the patient's brothers or sisters suffered from attacks like these, though a brother had had jaundice once in childhood.

Mrs. W. had her first attack of jaundice when about five years old, and has had repeated attacks since. With the jaundice there were associated pains in the upper abdomen and vomiting. She had one attack whilst pregnant with the child whose condition has been described; there was no elevation of temperature during an attack observed in September of last year. The liver was found to be considerably enlarged and the spleen also; the patient is troubled with an indolent ulcer on the right leg, its onset dating from before marriage. Urobilin and bile were absent from the urine in specimens examined in the attack in September, 1901. The examination of the blood showed the same characteristics as that of the son except that there were no nucleated red corpuscles. Both patients have always resided in England. There is no evidence in either case of hectic infection; both mother and son are very temperate; during infancy a little brandy was given to the son daily for about a year.

Very similar attacks occurring in three generations have been described by Dr. Claude Wilson, and Dr. Finlayson has called attention to their occurrence in several collateral members of a family.

The special points to be noted in the above two cases are (1) the chronicity of the affection, lasting in the son at least fourteen years and being probably congenital, and in the mother for a much longer period; (2) the occurrence of indolent ulcers in both cases; (3) the jaundice is always slightly present and undergoes periodic intensification, and is then associated with pain in the liver or spleen or in both; (4) Mrs. W. would appear to be a case of Hannon's cirrhosis of the liver, whilst her son's cannot but be considered as an earlier incomplete stage, possibly of the same malady; (5) finally, attention is called to the extremely guarded prognostic view to be held in such cases. Mrs. W. has grown to maturity and has had a family of several children, but for the disturbance caused by the periodical attacks of jaundice and abdominal pains is able to enjoy life. Two of the boys described by Dr. Wilson were under the

(a) Abstract of paper read at meeting of Clinical Society, May 23rd, 1902.

observation of one of us, and they appeared a few months ago to have lost all signs of the affection.

TWO CASES OF GASTRIC ULCER. (a)

By ALEXANDER BLAYNEY, F.R.C.S.I.,
Assistant Surgeon to the Mater Misericordiae Hospital.

WERE the case I am about to relate one in which the operation was a complete success, the patient never showing a subsequent bad symptom, I do not think I should be justified in bringing it forward. It seems to me, however, that its interest is just in proportion to its remoteness from the above gratifying result, about which we now so often read. Were we enabled to get the details of the unsuccessful cases, and the causes of the non-success as verified by subsequent post-mortem examination, we should, I feel confident, gain a much more accurate idea of the difficulties which have to be met with, and the best means of surmounting them than we do from reading the records of the eminently successful cases which are almost the only ones now published. While this paper mainly deals with a case in which the patient's life was ultimately saved, I shall preface it with the brief history of one in which the contrary result unfortunately took place, but in which the knowledge gained from watching its progress enabled me to save the life of my second patient.

The first patient was a girl, *æt.* 24, who had suffered from anæmia and symptoms of gastric ulcer for more than a year. While not performing any laborious work she got a sudden pain in the abdomen and felt very faint. She was removed to bed, where she vomited, and the pain became gradually worse. I did not see her till about twenty-one hours after the onset of the attack, when I found her with rigid, tender abdomen, a rapid pulse, and an expression of considerable anxiety. She had had vomiting two or three times since the first appearance of symptoms, and neither *feces* nor *flatus* had passed. She was immediately submitted to operation, and a rather small aperture was found near the pylorus. It was readily stitched up, there being but little induration in the neighbourhood of the ulcer.

The abdomen was well flushed out and closed without drainage. The patient rallied well from the operation; her temperature, at first somewhat elevated, began to fall; her pulse rate declined also, and everything seemed to be progressing most favourably up to about the sixth day. Her temperature then began to show an upward tendency and some pain was experienced. The temperature was higher next day and the pulse rate faster. A careful examination was made of her abdomen, more especially in view of her having a subdiaphragmatic abscess, which I knew to be a not infrequent sequel of gastric perforation. The area of liver dulness was normal, and all that could be made out was some tenderness in the neighbourhood of the wound which itself had healed by first intention.

I did not then deem the symptoms sufficiently alarming to justify a reopening of the abdomen. For the next two days there was no change, her temperature remained about 102°, pulse 120. The next night, about one, she got a violent pain in the abdomen, became collapsed, and died eleven days after operation, about seven in the morning, without my being summoned to see her. I made a post-mortem examination and found that she had suffered from a small subdiaphragmatic abscess, which had burst into the general peritoneum. The

rupture in the stomach was perfectly healed externally. I was not allowed to remove the stomach, and so did not see its internal aspect. On reflecting on this case I felt that she might easily have been saved by reopening of the wound while the abscess was still localised, and I resolved, if in any subsequent case a similar train of symptoms should make their appearance, to at once explore the abdomen, whether I could find localising symptoms of abscess or not.

L. S., unmarried, *æt.* 21, housemaid, was admitted on January 28th, 1902, suffering from intense pain in abdomen, with vomiting.

As a child had been quite healthy. Since puberty, however, has been delicate, suffering apparently from anæmia, as she states she was always pale, got easily breathless, and suffered from palpitations. She did not menstruate till she was 17, and since then has been always irregular, the menses appearing only at intervals of two to three months.

She began to suffer from pain in the stomach about two years ago, and during these two years she has been suffering from it, except for a few months when she was under treatment and returned home to the country. The pain came on about ten minutes after taking food; it was relieved to some extent by lying on her back with an inclination towards the right side. It was also relieved by vomiting, which usually followed within about an hour of taking food. The vomited matter was sometimes dark brown in colour but never contained unaltered blood.

The treatment which she received was apparently the administration of iron in the form of Bland's pills. This with a change to the country improved her condition, and the pain disappeared for some time. She stopped taking the pills about a month previous to her admission to the hospital. On the day previous to this she took a dinner, consisting principally of beef and bread, about twelve o'clock. She had some tea and bread and butter about five, and a similar meal at nine. She had had no vomiting that day. About half an hour after going to bed, and about eleven o'clock, she was seized with a violent pain in her stomach and left shoulder. The pain was constant in character with exacerbation at intervals of about three or four minutes. She vomited immediately after getting the pain about half a pint of brownish matter. She felt very cold, and was given brandy on two occasions, but it was promptly vomited each time. She was seen soon after her attack by a doctor who gave her two pills, which she retained. The pain remained all night. She was sent into the Mater Hospital about eleven o'clock next day, but I did not see her till about half-past five.

At that time her face presented a drawn appearance as of one in considerable pain. On examination of her abdomen it was found to be moderately distended, rigid, very tender on pressure in the epigastric region; tympanitic, the resonant area extending upwards for a considerable distance, and almost causing total disappearance of the liver dulness. The pulse was about 128, and very feeble. Temperature 100°. No *feces* had been passed since attack, but about 6 ozs. of urine were passed while in hospital. A diagnosis of perforated gastric ulcer was made, and she was at once submitted to operation.

A hypodermic injection containing 1.30th gr. strychnine having been given, the patient was anaesthetised with ether and a median incision about 5 ins. long was made between the ensiform cartilage and the umbilicus. There was a very thick layer of extra peritoneal fat resembling omentum in its appearance and at first giving me the impression that the peritoneum had been opened, when, as a

(a) Paper read before the Surgical Section of the Royal Academy of Medicine in Ireland

matter of fact, it had not yet been reached. However, the identification of the structure was soon established and the peritoneum opened. A considerable quantity of greenish coloured fluid came away, but there was no gas free in the peritoneal cavity. Large flakes of lymph were to be seen here and there on the intestines and stomach. There was some little difficulty in locating and reaching the site of perforation; when finally exposed it was found to be situated on the anterior wall near the cardiac orifice and close to the lesser curvature. It was about the size of a sixpence, and a considerable area of the stomach, for about $\frac{1}{2}$ in. all round, was found to be markedly indurated. The peritoneal aspect of the stomach in the neighbourhood was much reddened. The first Lambert sutures inserted, even at a considerable distance from the aperture, cut through. The next sutures were consequently put in even farther out; about half a dozen were put in before any attempt was made to tie them, so as to distribute the tension. The two folds of stomach were then held up by Mr. Hayes, who was assisting; while they were thus held in approximation the sutures were tied. A few more were then inserted, and finally a piece of the lesser omentum was turned down and stitched over the line of sutures. The upper portion of the abdomen was then flushed out with large quantities of sterile saline solution repeated till it returned quite clear, a gauze drain inserted down to the line of sutures, and the wound closed with through and through sutures of silkworm gut. The operation in all lasted a little over an hour.

The patient bore the operation fairly well. The early treatment consisted of the administration of nutrient enemata containing beaten up egg and brandy every fourth hour, liq. strych. 5 M. every sixth hour. Nothing was given by the mouth for five days, when some raisin tea was given, which was very agreeable to her. The gauze drain was removed next day, but owing to some doubt as to the security of the sutures it was replaced by some more gauze.

She continued steadily to improve, her temperature and pulse rate falling. Her bowels responded to an enema given on the second day after the operation, and moved spontaneously on the two following days. On the seventh day her morning temperature was 97°, her evening temperature 98.2°, pulse 64 and 80 respectively. From this on, however, both temperature and pulse rate showed a tendency to rise and on changing the gauze plug on the tenth day a slightly foul odour was perceptible. She was now complaining of some pain and tenderness, referred chiefly to the left of the wound. The temperature was 100.8° on the same night, and guided by my experience in the previous case I determined to reopen the abdomen, which was done on the eleventh day after the operation. I first explored the sub-diaphragmatic space on the right side, but found nothing. I then directed my finger towards the site of the original perforation, and after pushing it for some distance up I broke down an adhesion which allowed free some very foul-smelling pus. I could not for some time localise the aperture whence it came; it gushed out synchronously with the respiratory movements from some spot deep under the left dome of the diaphragm. In order to give myself room I then at once cut across the left rectus muscle and was now able to get my finger into the aperture, and on pushing it on it entered a large space filled with pus in the neighbourhood of the spleen. Considering the situation of the abscess cavity I did not think the anterior aperture would drain it thoroughly, and I accordingly cut down on the ninth intercostal space, which I made prominent by thrusting my left finger through the abscess cavity. The incision was so low down as to be

below the pleural reflection, so that the danger of an empyema was avoided. A large drainage tube was inserted here. The anterior wound was closed except the upper angle of the longitudinal wound and the outer angle of the transverse wound which were plugged with gauze. A copious dressing was then applied and the patient sent back to bed.

The effect of the operation was to cause an immediate drop in the temperature to 98.6° on the same evening. However, it rose again, and for the next ten days it remained up, reaching as high as 102° on the twentieth day after the original operation. At this time, too, the patient got an attack of diarrhoea and vomiting and complained of pain, this time on the right side of the wound. As the pain continued I again explored the subdiaphragmatic space, first with an exploring needle and subsequently with my finger (no anæsthetic), but with negative result. However, from this on the progress of the case was steadily towards recovery. The temperature fell to normal, in about five days more the pulse rate came down, the discharge from the posterior drainage tube gradually diminished, and the anterior apertures in which the gauze had been placed filled up with granulated tissue and healed in.

I was enabled to show the patient at the last meeting of the Surgical Section on April 4th. At that time the anterior wound was quite closed and the posterior almost. Complications were not yet done with however, for on the following Friday, a week after she was shown, her temperature was up again. Next day on examining the anterior wound I found it inflamed and a fluctuating swelling could be made out underneath. On incising this, about two ounces of foul smelling pus were evacuated. The opening at once brought relief. Her temperature fell, the odour and discharge gradually diminished, and with the exception of a very small sinus, she is quite well.

As regards her food during the course of her treatment. Raisin tea was the first thing given by the mouth about the end of the first week. This was continued alone for about three days. She then got milk and lime water, beef juice, then in a few days milk puddings, a beaten-up egg, and about the end of four weeks a little bread. About a fortnight later she got some chicken, and when leaving hospital was on the ordinary diet. The stomach symptoms from which she suffered two years previously have completely disappeared, and she has now absolutely no pain after a meal.

Such in brief is the history of the case which I have thought worthy of presenting to your notice; it had many points of interest for me, of which I should like to select for special mention two. The first concerns the formation of the perisplenic abscess and the symptoms associated therewith. There seems to me to be two possible explanations of its origin, the first and more probable that the primary flushing out of the abdomen was imperfect, and some bacteria containing extravasation having been left behind an acute, but localised inflammation was set up, terminating in abscess formation. The other that a subsequent giving way of the suture line allowed of a secondary perforation terminating in localised abscess formation. As against the latter theory there was absent the history of any sudden onset, and, furthermore, there was never any evidence of stomach contents in the discharge from the cavity. Taking, then, the first theory as the more probable one, what strikes me most forcibly is the steady fall of temperature and pulse rate, notwithstanding the formation of an intraperitoneal abscess, which at the time of opening contained more than a pint of fœtid pus. The explanation of this I must leave to other and wiser heads. The moral is obvious, never be betrayed into

giving a positively favourable prognosis after such an operation because of a steady fall of temperature and pulse rate in the first six or seven days.

The second point I should like to dwell on is that in both the extravasation was limited to the upper portion of the abdomen. This I attribute to the condition of the transverse colon, which in both cases I found distended and pushed upwards, overlapping to a considerable extent the stomach, and giving the explanation of the resonant note which was to be made out over the lower part of the hepatic area. In neither case was there any free gas inside the abdominal cavity, the presence of which used formerly to be postulated in every case in which there was disappearance of the area of hepatic dulness.

TWENTY-ONE CASES OF GASTRO-ENTEROSTOMY

FOR

INTRINSIC STENOSIS OF THE PYLORUS. (a)

By F. M. CAIRD, F.R.C.S. Ed.,

Assistant Surgeon, Royal Infirmary, Edinburgh.

IN dealing with the indications for gastro-enterostomy it was pointed out that they were in the main similar to those for gastrostomy, namely, difficulty in the onward passage of food, vomiting, progressive emaciation, and subnormal temperature. When these were present operation could not be delayed without serious risk. He held that it was erroneous to say that gastro-enterostomy was in itself an operation of great danger and of doubtful value in so far as prolonging life was concerned. Even if life were not prolonged by it, the patient at least did not die of starvation, his discomfort was lessened, and pain might be completely removed. Even in undoubtedly malignant cases there was sometimes so great a gain in weight after the operation as to call the diagnosis in question for a time at least. Moreover, in some cases the tumour entirely disappeared after gastro-enterostomy. Of his twenty-one cases only one was said to be simple—a stricture due to gastric ulcer, and at the operation the diagnosis was confirmed. In only one case was no tumour to be felt. The principal symptoms were vomiting, emaciation, and absence or diminution of free hydrochloric acid after a test meal. On the whole, the speaker preferred a posterior gastro-jejunostomy as close to the duodenum as convenient, or in the complicated cases an anterior operation. The choice of a method was largely determined by what was found on opening the abdomen, and to what extent the stomach remained mobile. He did not think that it made much difference whether the food current was isoperistaltic or anti-peristaltic. No special preparation of the patient was required; unless the patient was accustomed to it, lavage was not practised. If the general condition was poor teaspoonfuls of warm milk and water were given on the evening of the operation, and a small dose of morphine if there were pain or restlessness. On the morning succeeding operation, if there were eructations, vomiting, or quickened pulse the stomach was washed out, a procedure from which Mr. Caird had seen nothing but good, although one must be prepared for, and guard against, syncope. If the pulse still remained rapid after lavage, then thirty ounces of saline solution should be transfused; this often gave markedly good results. Of his twenty-one cases four proved fatal: one patient died of broncho-pneumonia and congestion of the kidneys, the abdominal wound remaining healthy; a second patient died from exhaustion, and a third from leak-

age through the wound in the stomach; in a fourth case fatal peritonitis ensued, probably from aerial infection. Of the seventeen patients who survived the operation three had been lost sight of, and were probably dead, six were certainly dead, three from extension of the disease, two from cardiac failure, and one from phthisis; while eight patients were alive at periods extending up to six years after operation. A second laparotomy had been performed on two—in one for ventral hernia, and at the operation no trace of the old tumour could be found; in a second for nodules in the cicatrix, and here again the abdomen appeared free from disease. It might be asked whether cases which survived for six months were really malignant, but while the difficulty of differentiating simple hyperplasia from carcinoma might be extreme, it was hardly possible that experienced physicians could be so frequently in error about cases which showed all the clinical features of cancer. It was impossible to ascribe the great improvement in the patients to laparotomy alone, though Stridell and others had reported improvement in abdominal cancer after simply opening the abdomen.

Therapeutic Notes.

By GEORGE FOY, M.D., F.R.C.S.,

Surgeon to the Drumcondra Hospital, Dublin.

SALTS OF SILVER.

THE introduction of salts of silver into medical practice dates from the middle of the eighth century, and is usually credited to Abu Musa Dschahir, of Damascus, who, during his sojourn in Seville, in Spain, about the year 140 of the Hegira, discovered his aqua fortis, oil of vitriol, corrosive sublimate, and lunar caustic; its name recalls his "astrology of the lower world," and gives a glimpse of his alchemy. From those days to this silver salts have held a place in the armamentarium of both physician and surgeon. They were first recommended for internal use by Rhazes and Avicenna. In time they came to be considered as specifics for many diseases, and were favourites with Boorhaave, Boyle, and Lewis. Cullen, however, noted a defect. He writes (1772):—"Internally it may be of service, when the crystals are rendered milder, by extracting part of the acid." For many years attempts were made to produce a salt less caustic than nitrate of silver, but possessing its therapeutic properties. As a rule these all failed. We had to wait for the discovery that organic radicles combine with and modify inorganic ones. Even when Kane explained the composition of white precipitate, he was so far in advance of the chemistry of his day that the value of his wonderful discovery that is the basis of our knowledge of substitution products was unrecognised; when, however, Bunsen produced kakodyl, chemists at once recognised the importance of the discovery, and a new impetus was given to the formation of organo-inorganic salts that has as yet shown no loss of force.

Of this we have evidence in the silver salts of the Chemische Fabrik von Heyden, of Dresden, who, by combining organic acids with the metallic base, have furnished the medical profession with some choice products, which combine silver in the way that Cullen predicted as the only manner to make the metal a useful therapeutic agent. To ensure accuracy and to protect their own interests the manufacturers have given the salts fancy names, to wit: Itrol, actol, and collargolum. Itrol, a pure citrate of silver. Actol, a pure lactate of silver, and collargolum, an amorphous form of silver.

These salts, itrol and actol possess the antiseptic properties of the base without any of the caustic albumen coagulating properties of the nitrate, and already a considerable amount of literature on their therapeutic properties has been called into existence.

Itrol is a fine white powder, odourless, and in a 1 in 4,000 solution may be used as a cleansing wash for

(a) Abstract of Paper read before Edinburgh Medico-Chirurgical Society, May 7th, 1902.

wounds or ulcers. It prevents decomposition and breaking down of tissues; promotes healing, and lint wet with it forms a good dressing for wounds. It is free from the irritating properties of the commercial salt, the use of which is so often followed by eczema.

Actol, the lactate of silver, is even more energetic as an antiseptic, and in five minutes a 1 in 4,000 solution sterilises cultures of *B. streptococcus*, *B. staphylococcus*, and others.

Dr. Röder has for the past two years used itrol and actol, both separate and combined, as a dressing for wounds and as a general antiseptic, and speaks highly of their properties and of the rapidity with which wounds heal under their use.

Dr. P. Vielt, Homburg, in the *Allgemeine Medizinische Central. Zeitung* asks: "Is collargolum a specific against sepsis?"

He has tried the preparation in phlegmonous erysipelas, lymphangitis, pneumonia, diphtheria, scarlatina, appendicitis, pyæmia, and puerperal fever. By the clinical reports of twenty cases he describes his method of using the collargolum and its action. Suffice it to say that the results were so satisfactory that he gives an emphatic affirmative to his own question, and if clinical cases are worth anything he shows that collargolum, when properly used, is a valuable remedy—a useful addition to our list of therapeutic remedies; useful alike to the physician and the veterinarian.

VERATRUM VIRIDE IN PUERPERAL ECLAMPSIA.

Signor Mangiagalli (*Class. Intr. docen Med. Mod.*) has recently been treating all his cases of puerperal eclampsia with tincture of veratrum viride, the use of which in such cases he thinks is not as well known on the Continent as it should be. He considers it to be superior to any other drug in eclampsia prior to or after parturition; and it has the advantage that it in no way interferes with the use of other medication. It may, when necessary, be administered hypodermically. It is one of the oldest remedies for producing dilatation of the os and controlling the eclampsia spasms in midwifery. It cannot, however, be used without great care as it is possessed of lethal properties of a very marked character.

It paralyses, almost without exception, every part of the peripheral and central nervous systems. The paralysis is preceded in various organs by stimulation. As the action advances the muscles become paralysed. Especially does this occur in the case of the muscle, and probably also of the motor ganglia, of the mammalian heart. Veratrum viride and v. album act at first as irritants or stimulants, and then as paralyzing agents, upon the terminations of the motor nerves of the voluntary muscles, upon three of the inhibitory fibres of the heart, upon those of the sensory nerves of the skin and mucous membrane, and, finally, upon those of the centripetal nerve fibres in the lung.

It should, however, be said that when a dangerous dose is administered the first effect of the drug is to produce vomiting, a fact which explains the immunity from fatal results that follows on its use.

To produce its effects in puerperal eclampsia large doses must be given, twenty or thirty minims. Under its influence—to quote Professor Hare—"Veratrum viride bleeds a man into his own blood-vessels, and the indications for its use are the same in inflammation as they would be for bleeding."

The value of bleeding in puerperal eclampsia occurring in robust young women was the subject of a pamphlet by James Isdell, of Dublin, in 1874, and soon afterwards Fearn wrote to point out that the good effects of bleeding were secured by administering the veratrum without loss of blood.

There are some patients who cannot take even a small dose of the drug without vomiting. In such patients the dose of veratrum should be preceded by half-an-hour with a two minims dose of Battey's sedative solution of opium.

CINNAMIC ACID.

Dr. Alfred Mann continues to report favourably on the value of cinnamate of sodium in the treatment of tuberculosis.

The action of the sodium cinnamate, the salt he uses, is to increase the number of leucocytes, so that the white corpuscles in the blood are almost doubled in number. It is on this leucocytosis that the curative process is supposed to depend. It is quite possible that this leucocytosis does not wholly explain the therapeutic action of the drug, for some of it becomes changed into hippuric acid, and is eliminated as such by the kidneys. Neither is it wholly innocuous, an overdose of the acid proving soporific in its effects and, on the lower animals, killing by arresting respiration.

Pure cinnamic acid is closely related to benzoic acid, and may be considered as benzoic acid in which one atom of hydrogen has been displaced by C_2H_5 . It forms salts with the alkali metals, which are monobasic and readily soluble.

Its effects in cystic troubles are almost identical with those of benzoic acid, which is a very much cheaper chemical.

The cinnamates of potassium and sodium, like thymol, are said to pass into the small intestine without being decomposed, and they are therefore recommended as suitable remedies in the tympany that is found so frequently present in severe cases of typhoid fever. That the acid is a valuable therapeutic agent is unquestioned, but we fear its high price will seriously interfere with its general use in medicine.

RADIUM AS A DIAGNOSTIC AGENT.

M. Javal, of the Academy of Medicine, Paris, has made the important discovery that radium emits certain rays which are capable of penetrating living tissues and producing an impression on the retina. Persons blind from glaucoma or from opacity of the cornea, can, if the retina is intact, recognise the rays. Taking advantage of this fact, M. Javal employs radium to test the condition of the retina in those who are suffering from blindness.

Clinical Records.

CASE OF

VAGINAL HYSTERECTOMY

IN WHICH SECONDARY HÆMORRHAGE OCCURRED ON THE FIFTEENTH DAY, AND WHICH WAS TREATED BY ABDOMINAL SECTION. (a)

By J. B. HELLIER, M.D. LOND.,

Hon. Obstetrical Physician, Leeds General Infirmary.

THE patient, a married woman, æt. 51, multipara, was found to have early cancer of the cervix uteri. The infiltration seemed limited to the cervix, and had not broken down much. The uterus was removed by vaginal hysterectomy, the operation being easy and not prolonged. The uterus being easily drawn down and the broad ligaments easy of access, the method of ligature was chosen, silk being used, and the ligament being tied in three portions on each side. The vagina was packed with gauze. Progress was good until the fourteenth day, when the last ligature came away and there was trifling bleeding.

On the fifteenth day violent secondary arterial hæmorrhage came on. Attempts were made to arrest the hæmorrhage per vaginam by searching for the vessel and by packing. These attempts were futile. The patient lost about thirty ounces of blood and was almost pulseless. It was therefore decided to perform abdominal section. The patient was placed in the Trendelenburg position, and the abdomen opened. There was no free blood in the peritoneum, the pelvic floor being sealed up by adhesions. A portion of omentum reached into the pelvis, and was adherent to the seat of operation. On separating adhesions much blood and a little offensive seropurulent discharge welled up. The adherent omen-

(a) Paper read before the North of England Obstetrical and Gynaecological Society, May 9th, 1902.

tum was now, with some little force, detached from its position and cut off. By employing Doyen's retractor to expose the pelvic cavity, and by allowing the electric light to shine in, the bleeding point was found and tied. It seemed to be a branch of the right ovarian artery. A gauze drain was passed from pelvis to vagina, and the abdomen was closed in by suturing the peritoneum with continuous catgut, and then passing silkworm gut sutures through the remaining layers, a few interrupted catgut sutures being passed to secure the apposition of the aponeurotic edges. A small drainage tube was left in the lower corner of the abdominal wound. This was done because the operator's fingers had manipulated the seat of hæmorrhage, which was certainly somewhat septic, and it was most likely that the wound was infected also. The patient made a good recovery. There was no further hæmorrhage and no peritonitis. There was some suppuration in the abdominal wound, as anticipated. Ultimately it healed well.

During the operation free use was made of hypodermic injections of strychnine and of intravenous saline injections.

Dr. HELLIER said he had only once before had a case of secondary hæmorrhage after vaginal hysterectomy, and that was after the removal of a clamp at the end of forty-eight hours. In this present case something had to be done and done quickly, and the treatment adopted seemed to him the only thing to do.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MAY 23RD, 1902.

Mr. HOWARD MARSH, F.R.C.S., President, in the Chair.

SIR THOMAS BARLOW, BART., and Dr. H. BATTY SHAW contributed a paper on

INHERITANCE OF RECURRENT ATTACKS OF JAUNDICE AND OF ABDOMINAL CRISES WITH HEPATO-SPLENOMEGALY, which is published in abstract on page 564.

Dr. ROLLESTON thought that the cases brought forward occupied an intermediate position between splenic anemia and Hannon's biliary cirrhosis in adults. He referred to certain families in the members whereof symptoms of both diseases had been met with. He recalled that certain French observers had described cases of Hannon's disease in which the spleen was also enlarged.

Dr. HERBERT FRENCH insisted upon the fact that one of the chief features of splenic anemia was the occurrence of hæmorrhages. In reference to the count of leucocytes which were said to have shown 10 per cent. of small leucocytes he pointed out that the special characteristic of the disease was an increase to 30 or even 40 per cent.

Dr. BATTY SHAW, replying, said they had been unable to examine the serum of the patient's blood, so that they could not say whether urobilin was present in the blood or whether it was real bile. In another case much urobilin was found in the urine, while in the blood real bile alone was found. He added that some of the counts had given a percentage of nearly 40 per cent.

Dr. W. HALE WHITE and Mr. C. H. GOLDING BIRD then gave

THE SUBSEQUENT HISTORY OF THREE CASES OF COLITIS ON WHOM RIGHT LUMBAR COLOTOMY WAS PERFORMED SEVERAL YEARS AGO,

which is published in full on page 563.

Dr. PERCY KIDD asked whether irrigations were always found to be harmful in these cases, mentioning that in a recent case irrigations had seemed to do good for a time; they also tried injections of nitrate of silver, which, however, had to be abandoned. This patient

appeared to be going on quite satisfactorily when hæmorrhage occurred with much pain, and in the course of a few days she died quite unexpectedly. No post-mortem was allowed.

Mr. A. BARKER thought that anastomosis of the ileum to the sigmoid flexure would expose the patient to the risk of regurgitation of fluid contents upwards. He mentioned the case of an elderly woman who came in with a huge abscess, the result of appendicitis. This had been opened very widely by a colleague, and she made a good recovery, but with a ghastly opening into the cæcum, which gave rise to much trouble. He then cut down and anastomosed the lower part of the ileum to the colon. This was followed by great improvement, but a very serious leakage persisted which prevented healing. Finally, some months later, he again operated, cutting right through the colon, and she made a good recovery. That case had made him doubt whether the operation of uniting the ileum and the sigmoid flexure would be a success unless it were cut clean through. The leakage occurred in spite of the fact that he had doubled up the gut at the first operation.

Dr. SYDNEY COUPLAND asked whether right lumbar colotomy was an operation that could be performed satisfactorily in the insane, adding that if practicable it would be a great boon, seeing that dysentery was very prevalent in large asylums, and accounted for 10 per cent. of the total deaths. These cases were often extremely prolonged; the patients would recover for a time and then relapse; in fact, they were the despair of the medical superintendents.

Dr. NORMAN DALTON suggested that it might be well to open the lower part of the ileum rather than the colon, and he related a case of a man who had had dysentery in South Africa, and had undergone colotomy. Six months later he was passing blood and mucus. He said he had had no injections through the opening. On examining him they found a large hernia of the posterior wall of the bowel which effectually prevented anything from the ileum passing into the colon. The man was treated by injections and got well. Mr. BURGHARD had operated and found that it was a piece of the ileum that was attached to the abdominal wall, and that enormously facilitated the closure of the bowel. In many of these cases the cæcum was much diseased, and after colotomy the fecal matter would get into the cæcum, whereas with an ileotomy it would not.

Dr. MONNIER-WILLIAMS related the case of a gentleman who passed twenty hæmorrhagic stools every day with great emaciation in consequence. They opened the colon on the right side, and then he steadily improved. The skin, however, became much excoriated by the liquid feces, and they had great difficulty in controlling the motions. He ultimately got quite well. With regard to injections he found that they improved matters greatly.

Mr. GOLDING BIRD, in reply, admitted that in ulcerative colitis antiseptic irrigations were very useful and, indeed, indispensable. In reply to Dr. Coupland he said he would be prepared to colotomise any insane patients, the after-treatment of course falling upon Dr. Coupland. He agreed that one might get a better spur from the ileum than from the colon.

Dr. HALE WHITE suggested that if anybody did do the anastomosis of the ileum into the sigmoid they would in many cases not get below the seat of the disease. After Dr. Monnier Williams' experience one might well flinch shy of opening the cæcum.

GENERAL MEETING.

Before proceeding to the business of the general meeting the PRESIDENT said he could not allow the occasion to pass without saying a few words with regard to the loss the Society had sustained in the person of Dr. ORD, who had probably done more for the Society than anyone except the founders. He described Dr. ORD as the type of the great physician, being also a great and enthusiastic physiologist and pathologist. He enumerated some of the contributions of the deceased Fellow, which showed how wide were his sympathies and how extensive his learning.

The business of the general meeting was then pro-

ceeded with. The report showed the Society to be in a flourishing situation. The selection of officers for the ensuing year having been announced, the usual votes of thanks to the retiring officers and members of Council were passed, and the Session came to an end.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, MAY 7TH, 1902.

Dr. T. R. FRASER, President, in the Chair.

Dr. NORMAN WALKER showed four cases of lupus treated by various methods of photo-therapy.

Mr. ALEXIS THOMSON exhibited a patient after removal of a hyperostosis of the upper jaw and malar bone. The condition had been present since birth, but the jaw had increased greatly in size since the patient had received a blow on it from a stone some years ago. In operating an incision like that practised for removal of the upper jaw had been employed, and the hyperostosis was found to consist of soft bone, cutting just like hard cheese.

Dr. MACBRIDE showed a case of nasal deformity treated by paraffin injection.

Mr. H. T. STILES showed (1) a boy who in November of last year had suffered from ordinary otitis media, which was followed by a convulsion, with subsequent paralysis of the right arm. The paralysis improved somewhat, but about the beginning of March an abscess formed in the right fronto-parietal region. This was opened, and about a week later he was admitted to hospital. On admission he was found to have slight paralysis of the left arm, and a suppurating sinus on the right side of the scalp through which a probe could be passed into the cranial cavity. On operating a large abscess was found between the meninges. The boy had improved greatly as a result of the operation, but suffered from complete optic atrophy of the right eye and partial atrophy of the left disc. (2) A child after treatment of congenital dislocation of the hip by Lorenz's method, with a skiagram by Dr. Rainy.

Dr. ALEXANDER BRUCE showed (1) two cases of paralysis and spasm of the ocular muscles, one due to lesion of the sixth nerve nucleus, resulting from a fall, showing complete paralysis of conjugate deviation of the eyes to the left, while the movements to the right were almost normal; the other, a case of spasm of convergence in which the patient had become run down and suffered from dimness of vision whenever she looked at a near object. The spasm remained permanent until light was excluded from the eyes. (2) Two cases of spastic paralysis following whooping-cough. The patients were brother and sister, at 9 and 12 respectively, and up to four years ago, when they suffered from pertussis, they were in good health. The boy had a convulsion then, and about a year later began to suffer from weakness in the legs. The girl was affected in a similar way shortly after her brother. In both cases there was marked spastic paralysis with increased knee-jerks and ankle-clonus, inability to walk, and mental deterioration. The whooping-cough was most likely a predisposing cause. Both children were the subjects of hereditary syphilis, with bossing of the forehead and typical teeth.

Dr. W. G. SYM showed a case of spasmodic contraction of the right inferior rectus, causing diplopia on looking down and to the right.

Mr. COTTEBILL showed (1) a case of multiple scirrhus healed by oophorectomy and X-rays. The patient suffered from recurrent nodules in the scar of a previous excision of the breast, as well as from growths in the other breast and in the glands in the neighbourhood. The local condition being inoperable, oophorectomy was performed, and was followed by great improvement for four months, when the catamenia returned, and the disease began to spread. Ultra-violet rays were now being employed with some benefit.

Mr. C. W. CATHCART demonstrated a portable stretcher adaptable to the Trendelenberg position.

Drs. MELVILLE DUNLOP and STUART McDONALD

showed a liver from a case of congenital obliteration of the bile-ducts.

Mr. F. M. CAIRD read a paper on

GASTRO-ENTEROSTOMY:

Twenty-one Cases Performed for Intrinsic Stenosis of the Pylorus. An abstract of this paper will be found on page 567.

Dr. LOVELL GULLAUD read a paper on

CYTO-DIAGNOSIS IN PLEURAL EFFUSIONS.

The examination of the cells in a pleural effusion was important chiefly in serous cases; in empyema, for example, the micro-organisms alone were important. It had been for many years a matter for discussion whether ordinary acute serous pleurisy was idiopathic, "rheumatic," tuberculous, or infective; at one time all were considered idiopathic, and recently the tendency to regard all as tuberculous was increasing. The main point of diagnostic importance was whether a pleurisy was or was not tuberculous. Very often it supervened in a case of phthisis, and here no difficulty arose, but where it occurred in apparently healthy persons there might be great difficulty, as the effusion might conceal the signs in the lungs. If the pulmonary mischief were slight there might be no sputum to throw light on the case, while as the patients were usually pyrexial the injection of tuberculin was not available for diagnostic purposes. Practically, the sero-diagnosis of tubercle was not a great help, nor did the morphological examination of the blood prove of service in slight or chronic cases. As regards the exudate organisms might be found, but in undoubtedly tuberculous cases it was often difficult to demonstrate bacilli, either because of the strong bacteriocidal action of the serum, or because of their small number, or because the exudate was due rather to the toxin than to the organism itself. The methods in cyto-diagnosis were simple. The fluid usually required to be centrifuged unless the cells were very abundant. Cover-glass preparations were fixed in 10 per cent. formalin-alcohol and stained with eosin and methylene blue or Jenner's stain. To show fat or glycogen granules in the cells, sudan, followed by hematoxyline or iodine, should be used. The exudate cells were derived either from the blood or from the tissues. Of the former the polymorphonuclears and the lymphocytes were of the greatest importance. Red cells, basophile-leucocytes, and eosinophiles were not of any special significance. In fresh exudates the polymorphonuclear cells resembled those in the blood, but after a day or two they underwent degeneration, either fatty or glycolytic. The nucleus either ceased to stain or lost its network and stained darkly and homogeneously. When this occurred the lobes of the nucleus often broke up and the cells divided, giving rise to an appearance like nucleated red corpuscles. The lymphocytes resembled those in the blood, and did not degenerate like the polymorphonuclears. As to the tissue cells, they were derived mostly from the pleural endothelium—larger than a leucocyte, with rounded nuclei, and often showing fatty degeneration. The main points of diagnostic importance were as follows:—(1) In tuberculous effusions during the first three days the cells were mainly polymorphonuclear, but by the third day these were almost entirely replaced by lymphocytes. This character held good of tuberculous effusion during the whole course after the third day; the lymphocytes amounted to at least one-half of all the cells found. A true lymphocyte effusion was thus of great importance, and it was because degenerated polymorphonuclears simulated the lymphocytes that he had described them. Sometimes they were so numerous that a polymorphonuclear effusion might be mistaken for a lymphocytic one. (2) In pneumococcal and streptococcal effusions there was always a great preponderance of polymorphonuclears, and often also numerous endothelial cells. (3) In oedematous effusions there were very few cells, and these always endothelial. (4) In malignant pleurisy cancer cells could usually be found, sometimes in great abundance, and a proportion of polymorphonuclears was also present.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

AN ORDINARY MEETING OF THE SOCIETY WAS HELD AT LEEDS, MAY 9TH, 1902.

Dr. S. BUCKLEY, President, in the Chair.

SPECIMENS.

PROFESSOR C. J. WRIGHT (Leeds) showed a series of plaster casts illustrating the effects of birth moulding in various presentations upon the shape and diameters of the fetal head. The positions shown were:—

1. Occipito-anterior vertex.
2. Occipito-posterior vertex.
3. Head following pelvic position.
4. Face.
5. Brow.
6. Vertex after delivery through flattened pelvis.

The models were obtained from Berlin for teaching purposes.

Dr. HELLIER (Leeds) showed a proliferating polycystic tumour of doubtful nature growing from near the ovary. The cyst walls were very thin and contained clear limpid fluid.

Dr. J. E. GEMMELL (Liverpool) showed a specimen of Tubal Abortion.

Mr. H. LITTLEWOOD (Leeds) showed a pair of very dense solid ovarian tumours, and other specimens.

Dr. H. BRIGGS (Liverpool): (1) Large double pyosalpinx. (2) A pedunculated sub-peritoneal uterine fibroid which had undergone strangulation.

Dr. A. E. WEAR (Leeds): A placenta with extremely marked calcareous degeneration.

Dr W. MURRAY CAIRNS (Liverpool) related a case in which he had performed craniotomy and cranioclast for face presentation with impaction in a contracted pelvis. The patient was pregnant for the tenth time, six of the previous labours having been difficult and instrumental. Dr. Cairns saw the case when labour had been in progress for thirteen hours. The os was fully dilated, the face presenting and the head impacted at the brim. The liquor amnii had already drained away. The forceps was applied and failed and version was found impossible. The head was perforated through the anterior fontanelle and extraction completed with the cranioclast. Dr. Cairns was of opinion that with the improved modern methods of performing Cæsarean section, the treatment he had been obliged to resort to in this case would only be justifiable in very exceptional cases.

Dr. MURRAY CAIRNS also mentioned a case of intra-uterine strangulation. An extremely neurotic patient, æt. 32, in her first pregnancy, suffered great discomfort from the tumultuous movements of the fœtus in utero. The symptom was alleviated somewhat by bromide of potassium. For several days before premature labour came on at the eighth month, the movements had entirely ceased. The fœtus, when delivered, had evidently been dead some days. The cord was very short, and was drawn tightly round the child's neck. Round the neck was a mark left by the pressure of the constricting cord.

CASE OF VAGINAL HYSTERECTOMY.

Dr. HELLIER, of Leeds, read notes of a case, which will be found under "Clinical Records."

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, May 25th, 1902.

LUXATION OF THE PUBIS.

At the last meeting of the Académie de Médecine, M. Mignon communicated an interesting case of sub-luxation of the pubis. He was called to see a man who had a fall from his horse, and slight hæmaturia was the result; he considered it a case of fracture of the pelvis, and passed a catheter, which was left *in situ*. The following day he was obliged to correct his diagnosis, for the pelvis was not fractured, but there existed evidently a sub-

luxation of the pubis. The membranous portion of the urethra was completely ruptured. Unable to suture both ends of the canal on account of the retraction of the inferior segment, he was obliged to leave the catheter a *demeure*. After some weeks the patient left the hospital cured.

SURGERY OF THE KIDNEY.

M. Honzel related the case of a woman, æt. 36, on whom he had incised the kidney for pyonephrosis. Some time afterwards she returned in a very cachectic condition, and nephrectomy was advised and performed. The perirenal adhesions rendered the operation particularly laborious, and the vena cava was torn to the extent of half an inch. M. Honzel tried at first to place a lateral suture, but the blood continuing to flow, he placed two ligatures, one above, the other below the vascular wound. The patient made a rapid cure, although a little œdema of the legs lasted some time.

HÆMORRHAGE.

To arrest hæmorrhage, vaginal, nasal, &c., a solution of gelatine produces excellent results in injections. The following formula can be employed:—

White gelatine	{ 3ijss.;
Chloride of sodine	
Formal, iij m;	
Water, 3iv.	

Plugs of cotton wool steeped in pure oxygen water also act well, but are a little painful.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, May 24th, 1902.

At the Surgical Congress, Hr. T. Sprengel, of Brunswick, spoke on

RECENT EXPERIENCES OF APPENDICITIS AND THE TREATMENT OF PERITONITIS.

The author dealt with the report of a collective investigation in a number of large institutions of which the staff favoured early operation. The investigation covered the period from December 31st, 1900, to the April of 1902. The following question has been proposed:— (1) What was the danger in late operations as compared with early ones? (2) Operation in an interval, operation in an attack; and (3) removal of the appendix. The total number of operations of four operators was 516. Of these 232 were in an interval and 234 during attacks. Of the first category only two died; of the second, twenty, so that the difference in danger to life is considerable. Operation should be considered early when carried out within twenty-four hours of the onset of symptoms, though even the gravest symptoms may be present then. There were no fatalities after such early operation as defined above. Early operation therefore gives the best results. The mortality of interval operation was enormously less than that performed during an attack.

Hr. Sonnenburg spoke on

LUNG COMPLICATIONS IN APPENDICITIS.

Lung complications were a known phase in laparotomy. Sometimes the symptoms were mild and the attack did not influence recovery. According to the speaker's observation the complication was not a frequent one. He had the conviction that the affection

was of embolic origin. Gussenbauer had already attributed it to this cause. Ether narcosis certainly did not set up the disease. He had not observed it even after thousands of narcoses. Exposure to cold was also not of any importance; he had never observed any influence due to the cold of winter. Hypostatic pneumonia was rare. Every exudation near the vermiform appendix readily gave rise to embolism. In lung affections the embolism was never from the portal system, but from the vena cava. He had seen thromboses and embolism in about 5 per cent. of his operation cases. In the Moabit Hospital, in 740 cases there were twenty-eight of various complications (fourteen thromboses); and in the sanatorium, in 260 cases nineteen lung complications.

The emboli were also of an infective nature. Emboli occurred also in operations performed during the interval. Emboli might also occur during the after-treatment, through the formation of thrombi. The reason for this was to be found in the fact that patients of the better classes were very anxious and had flabby hearts, whereby disturbances of circulation were caused. The thromboses were caused by tearing of vessels when the appendix was being freed from attachments. Embolism of the pulmonary artery did not betray itself by any special symptoms. If the lung complication were caused by embolism no digitalis was to be given, but the patients must lie in a raised-up position and morphia be given.

Dr. Doyen, of Paris, gave an address on the

TREATMENT OF GENERAL PERITONITIS.

The results of operation in infectious peritonitis had been very different, for the reason that cases had been included in statistics that could not be compared with each other. Thus many surgeons had thought they had cured a general peritonitis by laparotomy when the case was only one of circumscribed peritonitis (suppuration in the pelvis, the iliac fossa, subhepatic or subphrenic regions). A careful bacteriological examination of the fluid in the abdomen should be made, so that the favourable cases with sterile sero-purulent fluid might be distinguished from those infected with staphylococci, streptococci, and bact. coli. Regarding operative technique and its results he would observe: 1. The earliest possible diagnosis regarding the local condition, the pulse and the general symptoms. 2. The incision should go direct to the collection of pus. In sub-umbilical peritonitis the incision should be parallel to the right Poupart's ligament so that the appendix might be at once sought for. 3. For the protection of the peritoneum compresses should be at once introduced above and to the mid line. The appendix if necessary was to be removed, and the pelvis mopped out with compresses. Then toilette of the whole inflamed neighbourhood with dry sterile compresses without any flushing. 4. The toilette finished, the incision wound was to be closed, partially and drained with gauze and a glass drainage tube. 5. In case of extensive peritoneal effusion opening in the middle line; in case of collection near the spleen, on the left side. 6. He had never seen recovery in a case of acute general peritonitis when the exudation was septic and when it reached from the pelvis to the subphrenic region. Extensive washing out of the abdominal cavity was dangerous, its only effect could be to make matters worse by dissemination of the infection. 7. In intestinal paralysis an anus preter-

naturalis was made in the first section of the jejunum. This was closed in from ten to twelve days by a lateral enterocanastomosis.

Hr. Gluck, Berlin, discussed the

SURGERY OF THE LARYNX

with demonstration of one hundred operations on the larynx performed by himself. One case was operated on 4½ years ago by B. Fraenkel, for cancer of the glottis and the plica aryepiglottica resected *per vias naturales*. Three years later a carcinoma of the glands of the neck was removed by the speaker. The man was healthy and articulation intact. Several cases of diffuse papillomata of the larynx were treated radically after fissure of the larynx with permanent recovery and good speech. One case of exenteration of the larynx for tuberculosis. Total laryngoplastia by the speaker's method with formation of artificial laryngoschism after excision of the epiglottis along with the plicæ aryepiglotticæ. The patient did not wear a cannula. Still sound after four and a-half years, and speech perfect. Two children who had complete aphonia in consequence of development of cicatricial stenosis of the trachea. After tracheotomy low down transverse resection of the trachea in a healthy part was performed, and the two ends united. Speech was now clear. One patient, on account of laryngo-pharyngeal carcinoma, had an operation performed which embraced removal of the larynx, pharynx, the jugular vein and carotid artery of the left side, along with the glands affected. Recovery had lasted three and a-half years, and he had a clear pharyngeal voice.

In extirpation of malignant secondary tumours of the neck he proceeded as follows:—Central freeing of the large tissues of the neck, severance after double ligature. From the mastoid region he proceeds to the jugular foramen and the canal of the carotid; ligature and tamponade of the vessels; and then extirpation of the tumours with vessels and nerves, making the section through healthy tissues.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, May 17th, 1902.

LYMPHANGIECTASIS.

KREIBICH showed a few peculiar skin affections depending on lymphatic circulatory disturbances. The first patient was a man with vesicular lymphangiectasis on the lower side of the penis. Extension of the morbid process was prevented, and a cure effected by the removal of the lymphatic glands of the inguinal region.

He exhibited three other patients on whom he had operated for a similar condition.

The last was a female with the same disease on the under lip, angle of the mouth, and mucous membrane. Microscopic examination revealed a thickening of the endothelium, chronic inflammation of the internal walls, and extensive cellular infiltration.

The real cause of the lymphangiectasis in these cases was not perfectly clear. One of the patients, however, suffered from a distinct scrofulous cuticle.

Weinlechner related two similar cases which he had recently observed. The first was a young girl, æt. 14.

who had an elephantine thickening of the entire left leg. The skin was covered with vesicles from which exuded about a litre of lymph daily. There was also lymphorrhœa from the vagina.

In the other case the lymphorrhœa occurred in the forearm, and this was controlled by energetic cauterisation with nitrate of silver.

He thought it was a very strange thing that in spite of numerous operations of daily performance where glands were removed and lymphatic vessels wounded, lymphangiectasis was a very rare condition.

Exner thought the congestion of the lymphatics was not altogether due to the ecstasia because no ecstasia took place when the thoracic duct was tied in animals and no lymph allowed to escape. He was inclined to believe that the cause was due to some morbid change in the wall of the lymphatic vessel itself.

Ehrmann supported this view, as he had frequently met with the condition in cases of tuberculosis. He had also met with it in one case where gummata were found in the rectum. This is consistent with Kreibich's last case, where the cystic extension invaded the mucous membrane of the mouth and mucous glands.

Kreibich said that in all the cases shown he could find no morbid changes in the lymphatic walls; in the last case it was the ducts and not the glands which were enlarged.

PITYRIASIS LICHENOIDES CHRONICA.

He showed an elderly woman with serpiginous canceroid of the left arm, which had existed for three years, going through all the stages till the present cicatricial result was obtained. He then showed a girl, æt. 15, with pityriasis lichenoides chronica, of which only seven cases had so far been recorded, a fact which is probably due to its close affinity to syphilis in respect of its differential diagnosis. It affects the whole body in the form of reddish brown inflammatory papules with a horny desquamation. Mercurial treatment aggravated the disease.

Newmann thought the nosology of this disease was premature in the absence of any differential histological change. He related four similar cases which had recently come under his own notice that had every appearance in common with those exhibited, but he had classed them as specific.

CONGENITAL REGIONAL LIPOMATA.

At the "Gesellschaft" Lorenz exhibited a locksmith, æt. 49, whose right arm, when æt. 25, showed no sign of thickening. Since that time, however, the arm had gradually increased in size till it had reached 46 c.c., or 16.32 ins. and 42 c.c. in circumference in the upper arm, while the left arm measured less than half that circumference. For the last three years the affected arm had gradually got weaker till work had become difficult. The uniform cylindrical enlargement extended along the upper arm to the shoulder, as well as to the forearm, where it ceased at the hand quite abruptly. Palpation gave the impression of an incompressible elastic and non-fluctuating tissue of the upper arm, involving the muscular interstitial tissue, while that of the lower arm, on microscopical section, was found to be mostly in the subcutaneous cellular tissues arranged in layers of decalcified strata. The movement and sensibility of the arm were intact. The apparent reduction of the electric reactions is probably due to the increased thickness of fat. The

only apparent therapeutic treatment to be relied upon was excision.

GASTROSTOMY FOR IMPACTED BOLUS.

Hansy related the history of a specimen which he had removed from the œsophagus through the stomach. The patient had swallowed a large piece of food that stuck in the lower segment of the œsophagus, and would neither go upwards nor downwards by sounding or manipulation. To open the stomach was the only alternative, and this he did with the aid of a new clamp which rendered assistance unnecessary, at the same time keeping the lumen open while the contents of the bowel are securely retained. In gastro-jejunoscopy it is invaluable, safeguarding, as it does, the contents of the stomach, which pass on immediately on its removal.

Eiselberg confirmed the utility of the clamp in gastric operations, and assured the meeting that Hansy's modification by its greater curvature increased its usefulness in the hands of the surgeon.

AUTOCHTHONOUS LEPROUS TUBERCULOSA ANÆSTHETICA.

Gerber demonstrated a case of sporadic or isolated leprosa tuberosa anæsthetica associated with syringomyelia, who had recently died in hospital. The patient was 87 years of age. He had never been outside the narrow limits of his native town, Trancsin, until he came to Vienna for advice. The disease appears to have commenced about ten years ago in the form of gout, causing a flexure of the fingers which soon became powerless. This was associated with severe pain in the legs and atrophy of the smaller muscles of the hand. At this time the area of cardiac dulness appeared to have slightly increased, and there were signs of arterio-sclerosis. On the mucous membrane of the nose, cutaneous surface of the face and hips well defined plaques were observed, which were examined microscopically and found to contain lepra bacilli. Functional tests of muscles and nerves only confirmed the suspicion of serious transformations. There was loss of reflexes and extensive anæsthesia in both fore arms. He ultimately died of cachexia and cardiac failure. The subsequent examination of the spinal cord revealed a typical form of syringomyelia.

Lepra bacilli could nowhere be found in the spinal cord. Schlesinger said that he was of opinion that many of these obscure cases coming from the Austrian provinces were due to infection at the hands of isolated cases in wandering people who died under the diagnostic head of syringomyelia. He was bound to confess that the differential diagnosis was difficult and tedious, requiring months of observation to arrive at a trustworthy conclusion. He was confirmed in this opinion by his researches bearing on the subject in the Kingdom. He drew up a schedule of questions bearing on the subject, and sent one to every medical man with a request that it should be filled up as fully as possible, and returned to him. Among these questions was one asking the practitioner to furnish him with all obscure cases of syringomyelia in his practice. The differential diagnosis of leprosy and syringomyelia was attached for the guidance of the respondent. These facts led him to the conclusion that these two diseases were curiously confused or associated. In Gerber's case no one could doubt the presence of leprosy in conjunction with syringomyelia. The question arose whether there was any connection between these two diseases or whether the one induced the other? The absence of lepra bacilli

in the spinal cord was against the theory of the bacilla lepra inducing the eryngomyelia, and syringomyelia moreover was a disease of youth, and was not likely to have been the result of toxins, nor could it have induced the leprosy.

Lang thought small centres of lepra existed in towns of this description where intercourse was limited.

Neumann was of the same opinion, and related his experience of isolated cases in Bosnia.

The Operating Theatres.

GUY'S HOSPITAL.

AMPUTATION FOR TUBERCULOUS DISEASE OF THE KNEE-JOINT.—Mr. A. LANE operated on a man, *et.* 65, for extensive tuberculous disease of the knee-joint. The patient had suffered from the condition for a considerable time, and had in consequence become enfeebled and disabled; it seemed unwise to attempt to retain the limb by an excision. It was pointed out to the man that within a comparatively short period of time he would be enabled to walk with ease and comfort upon an artificial limb if the leg were amputated through the junction of the middle and lower thirds of the femur, and to this he willingly agreed, consequently the leg was removed, the method adopted being that usually employed by Mr. Lane in amputations, namely, a vertical incision along the length of the femoral vessel which is tied at its upper limit, the skin is then divided by a circular incision crossing the vertical at a sufficient distance in its length, the skin and subcutaneous structures are reflected and the muscles and bone are divided transversely at the level of the ligatured vessel by means of a sharp saw; in this way there is practically no loss of blood, nor is there any necessity to use an elastic or other compress to control the circulation in the part. The section made by the saw is perfectly flat and clean and any bleeding point is got at with great facility. The wound was stuffed with sterilised gauze for twenty-four hours, at the end of which time the gauze is removed and the skin edges brought accurately together by sutures.

The patient made an uninterrupted recovery.

HOSPITAL FOR SICK CHILDREN.

OPERATION FOR CLEFT PALATE ON A CHILD, AGED TWO DAYS AND A-HALF.—Mr. ARBUTHNOT LANE operated on a child, two and a-half days old, for cleft palate, which was complete and as bad as it well could be; the pre-maxilla projected from the under surface of the nose. The muco-periosteum on one side covering the alveolus and that portion of the hard and soft palate which existed, was removed from the subjacent structures along the whole length, and left attached only at the inner margin, forming a flap of considerable size. Mr. Lane's operation consists as follows: After his special gag has been fixed in position and the tongue drawn well forward, an incision is made through the mucous membrane and periosteum along the alveolar margin of that side to which the nasal septum is attached, and carried back along the extreme outer limit of the soft palate; then with an elevator the muco-periosteum is turned inwards off the bone, great care being taken not to damage this flap in any way; the descending palatine vessels and nerves are raised in a periosteal sheath, which is cut as long as possible and then twisted by

forci-pressure forceps, thus avoiding all hæmorrhage; the mucous membrane, with the thick subjacent layer of glandular and lymphatic tissue, is then raised from the under surface of the soft palate by means of a knife, with a round edge. An incision is now made along the margin of the cleft in the hard palate on the opposite side, and through this incision the muco-periosteum is raised from the bone by means of an elevator to a suitable breadth; next a thread is passed through the top of the uvula on the same side, and by pulling on this the posterior surface of the hard palate is exposed. An incision is then made through the mucous membrane on this aspect parallel to the margin of the cleft at a distance of about an eighth of an inch, the intervening mucous membrane being raised and turned inwards from the back of the palate, forming with the raw surface an oblong flap. The edge of the large flap is introduced beneath the edge of the elevated muco-periosteum covering the hard palate on the opposite side, and retained there by a double row of sutures; the portion of the flap corresponding to the soft palate is brought into accurate apposition with the oblong raw surface on the opposite side of the cleft, and also retained by a double row of sutures. In the present case the muco-periosteum along the opposing margin of the cleft was incised and raised from the subjacent structures, but the breadth of the cleft was too great to allow of its being covered in to a satisfactory extent by the reflected flap, and in order to meet this it was necessary to detach the anterior portion of the muco-periosteum completely from the bone; by means of this a considerable portion of the reflected flap was covered and connected. A similar procedure was adopted in the case of the soft palate. The muco-periosteum covering the pre-maxilla was used to close up the remainder of the cleft anteriorly on one side while the mucous membrane and skin were employed to fill in that of its fellow. The child bore the operation very well, which was necessarily long and difficult. Mr. Lane said that he was obliged to modify his ordinary operation very considerably in this owing to the very unusual breadth of the cleft. This consisted, he pointed out, in detaching the anterior portion of the flap completely from the alveolus and in dividing vertically the soft palate on the same side.

Pathological Society of London.

ON Tuesday, May 20th, the following were elected officers and Council for the year 1902-1903:—President, Right Hon. the Lord Lister, F.R.S.; Vice-Presidents, R.J. Godlee, M.S., W. D. Halliburton, F.R.S., E. Klein, F.R.S., and F. W. Pavy, F.R.S.; Treasurer, Sidney Coupland, M.D.; General Secretary, S. G. Shattock; Sectional Secretaries, H. Morley Fletcher, M.D., A. G. E. Foulerton, T. Grigor Brodie, M.D., and A. E. Garrod, M.D.; Council, R. Crawford, M.D., J. Fawcett, M.D., L. Freyberger, M.D., N. Dalton, M.D., G. F. Still, M.D., T. W. P. Lawrence, M.B., S. H. Habershon, F. W. Andrewes, M.D., W. Bulloch, M.D., John McFadyen, M.B., Allan Macfadyen, M.D., H. G. Plimmer, R. T. Hewlett, M.D., W. S. Lazarus Barlow, M.D., J. R. Bradford, F.R.S., E. H. Starling, F.R.S., C. A. Ballance, M.S., F. G. Hopkins, M.B., V. Harley, M.D., and S. G. Hédin, M.D.

SURGEON-GENERAL TAYLOR, Director-General of the Army Medical Service, inspected at Woolwich, on the 22nd inst., six companies of the Manchester Royal Army Medical Corps Volunteers, numbering 640, who had gone to Woolwich for their annual encampment. The men were quartered in tents near Herbert Hospital. Though the weather was extremely wet and unfavourable, they endured the discomfort very cheerfully.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 Os. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

WEDNESDAY, MAY 28, 1902.

THE AFTER-HISTORY OF THE CHILDREN BORN OF INSANE MOTHERS.

THE question as to whether the mind of the mother is capable of exerting an influence on the developing foetus is one which has attracted the attention of alienists for a considerable time. If maternal impressions influence the foetus in normal cases, then it would seem that, *a fortiori*, they would influence the foetus when profound mental disturbance is present, as in the insanity of pregnancy. Any facts and all statistics which bear on the elucidation of this problem are therefore of value, and for this reason, if for no other, an article by Mr. A. F. Tredgold, L.R.C.P., recently published in a contemporary, is of considerable importance. The difficulties in the way of tracing the after-history of children born in asylums or work-houses is considerable, as is shown by the fact that of a list of 121 women, who had borne children whilst in a state of insanity, a trustworthy after-history of both child and mother could only be obtained in thirty-eight cases. Of these children, thirteen were alive and in good physical and mental health, while of the remaining twenty-five, three were stillborn, nineteen died during the first year, and three before they had attained the age of three. Such statistics would appear at first sight to point strongly to an important influence of the maternal mental condition on the physical condition of the foetus, but Mr. Tredgold will not admit such an inference. In this he is apparently justified by the relative death-rate of children born of patients in whom there was no apparent morbid physical tendency, and of children in whom such a parental tendency was proven. Among the former group of infants, only four out of fourteen died, whilst among the latter group twenty-one out of twenty-four died. Accordingly, it seems justifiable

to assume that the diminishing vitality and death of the child were to be attributed to the ante-natal physical state of the mother, and not to her mental state. Such, then, is the physical condition of children born during the insanity of the mother so far as Mr. Tredgold's statistics can show, a death-rate among infants under a year in age of 580 per 1,000. The results of his inquiry into the mental condition of those who either lived long enough to enable this condition to be estimated, or who are at present alive, is still more interesting. Of the three infants who survived the first year, but died before they had reached three, one "had something the matter with the brain," another died of bronchitis, and a third of "wasting of the brain." All the children who survived, *i.e.*, thirteen out of thirty-eight, or what is perhaps even more significant, thirteen out of sixteen who survived their first year, are at present "of good mental and bodily development." The conclusions which naturally follow from these statistics do not, we fancy, agree with the preconceived opinion of most medical men, and still less do they agree with those of the general public. They do not constitute in themselves a final decision as to the effect of the condition of mind of the mother on the foetus, inasmuch as Mr. Tredgold's cases are not sufficiently numerous. But, so far as these cases go, we agree with him that the natural conclusions to be drawn from his statistics are that (1) the mental and physical condition of the child is in no wise influenced by the mere fact of the mother being insane during pregnancy; (2) neither is the condition of the child influenced by the variety of the insanity, the duration of the attack, or the age of the mother, nor even directly by the number of attacks from which the mother may have suffered; but that (3) *this condition is directly dependent upon the presence or absence of morbid hereditary influences.* Whether others working on similar lines as Mr. Tredgold will obtain similar results is another question, and one which we trust will soon be answered.

HEALTH RESORTS AND CONSUMPTIVES.

A RATHER disconcerting effect of the generalisation of a knowledge of the causes and nature of consumption has been to excite a feeling of distrust, mingled with apprehension, in the very health resorts which have hitherto been patronised by those suffering from lung disease. Not long since the hotel proprietors of the French Riviera met together, and with more enthusiasm than good sense, formally declared their intention of giving the cold shoulder to invalids. It is true that the outcry to which their action gave rise promptly brought them to their senses, and their *fiat* has since been considerably modified. Colorado is another popular resort of consumptives, not only those of American nationality, but to a not inconsiderable extent from these islands as well. The climate of Colorado rejoices in a world-wide reputation in the treatment of consumption, yet the idea has been mooted of a law having for object to prohibit the admission to this favoured

territory of aliens suffering from pulmonary tuberculosis. Naturally the health officers of Colorado have lost no time in contradicting a report which could not fail to deter many intending visitors; indeed, quite apart from any question of self-interest, we cannot imagine a body of medical men lending their support to such a wanton and injudicious scheme. These straws, however, show which way the wind blows, and we must be prepared for a certain hostility towards consumptives, akin to, if less drastic in execution than, the mediæval edicts enforced against those who sought to escape from plague-ravaged countries. This feeling was inevitable directly the public became possessed of that modicum of knowledge which is of such potential danger. The moment that the idea of the transmissibility of consumption became public property it was to be anticipated that the victims of pulmonary tuberculosis would fall more or less into the category of persons suffering from infectious diseases in general. The lay mind does not readily grasp the enormous difference between the various degrees of transmissibility. Of course this is only a phase of the evolution of knowledge, and in the course of time a juster idea of the actual risk of infection, which, in consumption, is comparatively small, will obtain. This fear, indeed, though it has its inconveniences, is calculated to exert a salutary influence, since it emphasises the necessity for destroying the *materies morbi* by which alone the infection can be conveyed; moreover, it will tend to check the marriage of persons admittedly consumptive. Returning, however, to the measures having for object to exclude these sufferers from particular areas, it is evident that they must infallibly defeat or overreach their object. There is little fear of any concerted action of the kind in regard to our native health resorts, because public opinion would promptly be brought to bear and if, in the Riviera or elsewhere, invalids do not receive the comforts and attention which are their right they have the remedy in their own hands. Since tuberculosis is endemic in all parts of the world, it is idle to attempt to exclude sufferers from other countries so far as the prevention of the disease is concerned. The proper course is to instruct the public more fully in the means of hindering its transmission, and this is rapidly being accomplished by the active propaganda which has been undertaken by the various societies and associations for the prevention of consumption. If there be one point more than another that has been irrefutably established by the clinical study of pulmonary tuberculosis, it is that infection is a factor which owes its power to the individual lack of resistance; in other words, we must teach the public how to live in order to obtain and preserve a "tissue immunity" against infection.

THE HYGIENE OF THE PUBLIC-HOUSE.

THE subject of public-house reform is one which is beginning to excite general interest, and there are signs that in the near future it may lead to far-

reaching legislative and administrative changes. The questions recently raised, however, relate to what we may call the moral aspect of public-house management, but it is remarkable that so little has been said respecting the hygienic aspects of the public-house. The importance of this matter has been well brought out by Professor Thomas Oliver in his recently published work on "Dangerous Trades." The keepers of public-houses have always been a notoriously short-lived class, and the formation of "tied" houses, by bringing about the disappearance of the older type of landlords, has, if anything, aggravated pre-existing evils. Barmen and dealers in alcoholic drinks are now exposed to conditions seriously inimical to health. They are often themselves of inferior physique, being in most instances taken from among town dwellers of low physiological grade. The life of a publican is necessarily sedentary. He has, moreover, to live in an atmosphere reeking with the odour of spirits, tobacco smoke, and emanations from the men and women who lounge at the bar. Many of his customers are the subjects of disease, and, as is well known, many of the frequenters of our public-houses are in advanced stages of consumption. The filthy condition of a very large proportion of public-houses, their floors covered with dried sputum and other organic filth, undoubtedly furnish a fruitful source for the dissemination of tuberculosis and other maladies. But the publican is also exposed to numerous temptations to drink excessively, and this, together with irregular meals, sooner or later induces structural alterations in the liver, lungs, and heart which bring life to a premature close. Dr. Oliver quotes Ogle to show that innkeepers and publicans have a comparative mortality figure of 1,521, as against 1,000 of the general population. Dealers in intoxicating drinks have a mortality of 68 per cent. in excess of the healthy male tables of the Scottish Amicable Insurance Society, and 49 per cent. in excess of the English Life Tables. Roughly speaking, the mortality is 51 per cent. above that for all males. In no other class of men is the mortality from alcoholism so high as in innkeepers and publicans. It is from five to seven times higher than the average. Dr. Oliver states that the only occupation which approximates to it from a mortality point of view is that of cabmen. It would be well if medical officers of health would recognise more fully than they generally appear to do what an important factor is the public-house in the propagation and dissemination of communicable disease. A stricter insistence on the maintenance of sanitary precautions, and a more vigilant watchfulness to see that hygienic requirements are not altogether neglected, would do much to mitigate the evils necessarily more or less closely associated with our present public-house system.

DR. ABRAHAM JACOBI has resigned the Chair of Diseases of Children in the Medical Department of the Columbia University, a post which he has held for the past thirty-two years.

Notes on Current Topics.

Foreign Bodies in the Brain.

THE brain is so securely ensconced in its bony envelope that it might reasonably be supposed to be adequately protected against the intrusion of foreign bodies, apart, of course, from violence sufficient to penetrate or shatter that natural coat of mail. This immunity, however, is more apparent than real, for it is a matter of almost daily experience in the post-mortem room for the most unlikely objects to be found nestling in this or that corner of the cerebral hemispheres. Even more remarkable is the fact that in a very large proportion of cases these intrusive substances have evidently occupied their beds for a long term of years, acute symptoms supervening quite unexpectedly under the impulse of some usually undetermined cause. Only last week an inquest was held at Charing Cross Hospital on a lad who had been admitted with symptoms pointing to cerebral abscess, and had died before there was time to operate. At the autopsy, a piece of slate pencil was found embedded in the left half of the brain which, after many years, had given rise to abscess and meningitis. Another noteworthy feature of these cases is that but very rarely is any history obtainable which would explain the accident. Children are very prone to push odd things into their noses and ears, but after all a certain degree of violence is required to effect the passage of a pencil, a pen or a skewer through the base of the skull. In some instances there is less mystery about the occurrence, as, for example, when an irate "fare" pushes his umbrella or stick through the cabman's eye into the brain, leaving the ferule embedded therein. In some instances the victims were quite unaware of the serious nature of the injury, and have casually strolled into a hospital for advice, the stick having slipped past the eyeball without inflicting obvious damage. Nor is there any obscurity when a "baby farmer" confesses to having deliberately pushed pins through the thin orbital plate into the frontal lobe, with the express object of causing premature decay—an experiment which has not always been crowned with success.

"Truth" and the Alabone Treatment.

MR. ALABONE may congratulate himself on having what the French call a *bonne presse*. Even the worldly-wise editor of *Truth*, after a desperate attempt to appear impartial, extends to Mr. Alabone the editorial approval which, in the past, has been so liberally dispensed to "popular" specialists in the treatment of obesity. After all, this merely emphasises the fact that the Alabone treatment meets with recognition only at the hands of those who are admittedly unable to draw any trustworthy conclusion. There is one point in the *Truth* articles which calls for surprised comment, and that point is the inference which the public is asked to draw that the ostracism inflicted by the medical profession on such of its members as keep their treatment secret is merely a manifestation of trades-union jealousy.

Now, this ethical rule is really the most striking and convincing evidence of the disinterestedness of medical men that could possibly be afforded. It would be immensely to the pecuniary interest of the profession if all were allowed to arrogate the exclusive right to a remedy or method of treatment, but it is held to be derogatory to the public interest, and is consequently tabooed. What a fortune might the discoverer of one or other of the many therapeutical innovations of modern times not have made had he thrown ethics to the dogs! Röntgen might be rich beyond the dreams of avarice, the inventors of the ophthalmoscope and laryngoscope might vie with the American plutocrats in filthy lucre, had they not generously thrown their epoch-marking discoveries into the public domain! To return to *Truth* and Mr. Alabone we might ask whether our contemporary has taken the trouble to institute any comparison between Alabone's *soi disant* percentage of successes in treatment and that of the average specialist. Obviously nothing of the kind could be carried through, yet without some such comparison what is the value of this *ex parte* approval? Our contemporary, moreover, is just as much at sea in respect of the judicial functions of the Royal Colleges and the General Medical Council as in its appreciations of the therapeutical import of Mr. Alabone's much-advertised and intrinsically worthless treatment.

The Fish Hypothesis of the Spread of Leprosy.

THE study of the natural history of leprosy is of the utmost importance to a great proportion of the inhabitants of the globe. The gradual disappearance of the loathsome malady in question before the improved sanitary conditions of modern civilisation suggests a hope that it will ultimately be banished from all other countries as well. It is therefore incumbent upon scientific medical investigators to weigh and consider carefully the various theories advanced from time to time as to the spread of the disease. Fortunately, the origin of leprosy in a specific bacillus may be regarded as established, but the same remark does not apply to the agency whereby it is distributed among a community. One of the most ingenious hypotheses yet framed has been that of Mr. Jonathan Hutchinson, who ascribed leprosy to the eating of uncooked fish. His view has not received general acceptance, as it failed to meet all the facts of the case. Quite recently Dr. Neve, one of the superintendents of the Kashmir State Leper Hospital, has pointed out several important facts relating to the fish theory. He found the disease rarer in women, who appeared to eat fish just as freely as the men. The incidence of the disease was not upon the districts where the greatest amount of fish was consumed. Many who had not eaten fish contracted leprosy. On the whole it seems safer to assume that while leprosy may be conveyed by the agency of uncooked fish, as by other foods, there is no evidence to show that such fish is

the principal means of spreading the disease. Leprosy may be regarded as in all likelihood following much the same course as tuberculosis with regard to its manifold avenues of attack upon mankind.

"Sprains" and Modern Science.

OF the numerous injuries classified under the conveniently general description of "sprains," the vast majority affect the ankles and wrists. There can be no doubt whatever that in many cases an obscure fracture has escaped notice, and has been thus diagnosed. Or there may be cases in which the exact apposition of the ends of broken bone, as in a transverse break of the tibia, have rendered accuracy of diagnosis difficult or impossible. The Röntgen ray methods have now come to the aid of the surgeon, and straightway this great class of obscure fractures has been rescued from the rubbish heap of sprains. Another class of injury that has also to a great extent been brought within the range of accurate diagnosis by the Röntgen methods is the separation of the epiphyses. It is surprising how, even at this hour of the day, many practitioners are found content with their diagnosis of sprain in cases where radiographic examination at once reveals a fracture. As a matter of routine method, any medical man who is called upon to deal with an obscure injury of the kind should resort at once to a skilled radiographer, with a view of securing further evidence. For many reasons it will be wiser to entrust the X-ray examination to a properly qualified medical operator. Should the injury turn out to be a fracture, the medical man will be protected from the risk of legal action for negligence and malpraxis and the patient will be fully informed of the actual state of matters. A radiogram should always be taken after the splints are applied in order to ascertain the proper reduction of the fracture.

The Diagnosis of Malaria.

THE use of the microscope in the diagnosis of malaria is invaluable, if the user has attained a sufficient degree of skill to read the signs which the blood affords. If he is not sufficiently skilled, as perhaps, is the case with the greater proportion of medical practitioners, it is better to obtain the opinion of an expert. Yet, even if this course is adopted, every medical man should be able to make a microscopical slide in such a manner as to enable an expert to form a definite and trustworthy opinion of the nature of the case. According to Dr. Patrick Manson the best mode of procedure is first to clean carefully with alcohol an ordinary microscope slip, and similarly to cleanse the patient's finger-tip or the lobe of his ear. The finger or the ear is then pricked with a clean and rather long ordinary sewing needle. A drop of blood is pressed out and, as it may contain epithelial debris, wiped away. A second but very minute drop of the size of a large pin-head is then expressed and touched lightly (the skin must not be touched) with the clean surface of the slip about an inch from the one end.

Immediately, the shaft of the needle is laid transversely on the droplet of blood so transferred to the slip. After waiting a second or two for the blood to run out by capillarity between the surface of the slip and the needle, the latter, held between finger and thumb, is drawn along the surface of the glass. In this way with a very little practice a beautifully fine and even film is produced. Half a dozen such films should be prepared. The single prick suffices as the films can be made very rapidly one after another. After they have dried they should either be wrapped in very clean tissue paper or placed in a dust-free slide-box and transmitted to the laboratory.

The Justus Test for Syphilis.

MUCH has been written concerning the value of the test first described by Dr. Jacob Justus, of Budapest. It is based on the fact that mercury, given by subcutaneous or intravenous injection, or by inunction, will cause a diminution in the hæmoglobin of the blood. In the healthy or non-syphilitic it was said that the loss was rapidly made good, while in syphilitics, twenty-four hours after the administration of the mercury, the amount of hæmoglobin will be diminished from 10 to 20 per cent. Papers by Dr. Henry Tucker and Dr. W. E. Huger (*Philadelphia Med. Jnl.*, May 10th, 1902) now show that Justus's test has no practical value in the differential diagnosis of venereal ulcers, since the reaction occurs with an almost equal degree of frequency in the non-syphilitic conditions with which syphilis may occasionally be confused.

The Act of Vision.

THE current number of *Harper's Magazine* contains an interesting contribution on "The Act of Vision," by Raymond Dodge, Ph.D. As this writer points out, it is but "a little over a year ago it was demonstrated that while the eyes are moving, as we look from one point to another in an ordinary complex field of view, we can distinguish none of the impressions the eyes receive." There are two illustrations: one for measuring the "reaction time of the eye," and the other for recording the movements of the eyes. Mr. Dodge points out that in moving the eyes across the page in reading, the progress is never continuous: it is interrupted by a series of stops. We have actually no power of moving our eyes slowly, and as is now well known, distinct vision requires exposure to the retina for an appreciable fraction of a second, we are actually blind to all external objects while the eyes are moving, and only see during the stops. He consoles the average reader whose envy has so often been excited by thinking of the intellectual genius who can take in two or three lines of print at a time. Such a feat must now be forever relegated to the lumber-room of stale miracles. The man of exalted mental powers may be able to read very fast, but while his eye is performing the sweep he never takes in even a single word. "More serious are such moments of blindness to the boxer or the fencer. Empirical expediency long

ago developed the maxim that both should fixate the eyes of the opponent. This is not merely to avoid giving cues of intended movement, but also to avoid the disastrously numerous moments of blindness which would result if one attempted to follow the motions of the opponent's hands." The writer points out an interesting physical fact which has probably not been noticed by some of our readers:—"All of us see a reflection of our eyes in a mirror many times a day, but no one of us ever saw his own eyes move." The fact that we can see our heads move, frequently produces "the illusion that we see our eyes during a movement of the point of regard."

Leprosy and Emigration.

In a recent number of the *Gazette des Hopitaux*, M. Jeanselme has given an interesting account—historical, geographical, and ethnological—of the relationship between the currents of emigration and the dissemination of leprosy in modern times. At the dawn of the modern era, the principal endemic foci of leprosy were found in Africa (West Coast), India, and China (Southern). One of the many malignant influences on the New World with which the Spaniards have been credited is the introduction of leprosy. The grounds of this accusation have been disputed, and will, probably, never be definitely established. But it is a historic fact that Cortes found it necessary to open a leper's home in Mexico as soon as he had established himself there. And in the parts of the Western Continent where the race of aborigines "a été refoulés, mais non pas détruite, aux Guyanes par exemple," it is still noticeable that the inhabitants possess their old indemnity from the disease. The Chinese fought and emigrated southward, and carried the loathsome plague with them into Annam, Burmah, Cochin-China, &c. The city of Singapore is still a veritable Chinese colony. And in that part of the word there is a deplorable prevalence of leprosy. And the Chinese have disseminated leprosy in all directions of their emigration. The negroes were largely instrumental in its dissemination in America. The torrent of Chinese attracted by the discovery of Australian gold in 1851 accounts for the infection of the junior continent.

Cacodylates as Therapeutic Agents.

COMPOUNDS of cacodylic acid have recently received much attention, and in certain quarters have been much lauded. Professor Fraser, in the May issue of the *Scottish Medical and Surgical Journal*, discusses the question of the relative inefficacy of cacodylates as therapeutic agents. He contends that clinical observations and chemical analyses agree in showing that when a salt of cacodylic acid is administered to a patient it is absorbed and is eliminated, but with the arsenic which it contains so firmly combined with the other cacodyl constituents, that it does not become dissociated, and is, therefore, incapable of forming any compound in the body that can produce the well-known pharmacological activities of the compounds of arsenic usually em-

ployed for therapeutic purposes. The compounds of cacodylic acid may be given in massive doses, and by them arsenic may be introduced into the body in quantities which are large and even enormous, relatively to the quantities in the commonly used compounds of arsenic, in which this element, however, is not so stably fixed as to be incapable of forming new combinations which produce well-known and powerful effects. Dr. Thomas Fraser regards cacodylates as both useless and inconvenient. This contention that compounds of cacodylic acid are of little or no value for producing the therapeutic effects for which arsenic is generally administered will doubtless not be allowed to pass unanswered. The whole subject stands in need of thorough and immediate investigation. We are glad to see that the use of arsenic in medicine is to be a subject for discussion at the forthcoming meeting of the British Medical Association, and we hope clear light may be thrown upon many of the points which still linger in obscurity.

Human and Bovine Tuberculosis.

COMMUNICATIONS relating to the relationship between human and bovine tuberculosis are appearing in bewildering profusion. Among the more important recent articles on the subject that of Professor Adami, of Montreal, in the current issue of the *Medical Chronicle*, should not be overlooked. Dr. Adami shows that bovine tuberculosis is easily conveyed from cattle to cattle, and that human tuberculosis is transmissible to cattle, but must be considered of singularly rare occurrence. He holds that everything points to the fact that in the main the bacilli causing infection in man are derived from previous cases of the disease in man, but admits that bovine tuberculosis can be transmitted to man, and this either through wounds or by means of the digestive tract. Dr. Adami rightly points out that had the agitation for municipal and governmental supervision of the milk supply and for the distribution of pure milk, been based upon what we know concerning contaminated milk in general and its dangers, rather than, as it was, upon the danger arising from the conveyance of tuberculosis, Koch's volcanic address would not have had nearly the same deleterious effect.

Liquid Air as a Freezing Mixture.

THE innumerable uses to which liquid air can be adapted if it once became a commercial success are very apparent, and chief among these will doubtless be that of a cheap refrigerator. A novel and yet most obvious purpose for which it has been already adopted in this direction is as a substitute for ether in freezing microtomes. Dr. Stoddart, assistant medical officer of Bethlem Royal Hospital, has lately drawn attention to its advantages and the satisfactory results obtained by its use. It is cheaper for such a purpose than is ether, as a gallon of it, which costs twopence, lasts in constant use in a laboratory for more than a fortnight. It

acts more rapidly than does ether and its effect lasts for longer. Further, the unpleasant smell of the latter is absent. In fact, so far from an unpleasant smell, a morning at the microtome with the fellowship of liquid air is, according to Dr. Stoddart, equivalent to a blow of fresh air in the country. To enable it to be used with a Cathcart's microtome certain modifications of the latter are necessary, but they are not such as add very greatly to its expense, as the entire apparatus can be purchased for the sum of thirty shillings.

Malingering as a Fine Art.

THERE is no more difficult task for the medical man, no matter in what place his lines are cast, than the detection of malingering. Sooner or later the pitfall awaits every practitioner, and well for him if he proves equal to the occasion. The golden rule of safety is probably to be found in cautious investigation and in temporary suspension of judgment should there be any doubt favourable to the suspected malingerer. That course, however, will not furnish absolute immunity to the medical attendant, as shown in a somewhat amusing manner by a recent case at Exeter. A young married woman of that town prosecuted a boy of ten years for unlawfully wounding her with a hatchet. She appeared in court apparently in great pain, with her arm done up in splints. Some doubt evidently arose in the mind of the magistrate, for he adjourned the case so as to have the evidence of the house surgeon at the hospital where prosecutrix was attended for the alleged injury. That gentleman stated emphatically that when the woman came to the institution he could find no incision, abrasion, bruise, or fracture. He put the arm up in splints as a matter of precaution, as the woman complained at the time of great pain and tenderness. The magistrate dismissed the case, and expressed his conviction that the patient had used the splints for the purpose of getting a warrant against the boy. This incident is worthy of a place among the annals of malingering, and it well illustrates how a crafty woman will not scruple for her own ends to play upon the sympathies of a busy medical man.

Arboreal Traits in the Human Foot.

FOR long it has been claimed that arboreal traits are to be seen in the grasp of the new-born baby's hand, which, as is well known, may be sufficiently strong to hold the infant's whole suspended weight. Dr. E. H. Bradford, in an interesting paper in the May number of the *Journal of Medical Research*, now shows that there are evidences of arboreal ancestry to be found in the movements of the human infant's foot. The study is of much interest, particularly if we accept the view that it is due to his superior foot that primitive man was so successful in the combat with other animals, and drove the more powerful ape from the continent of Europe into the impenetrable forests of Central Africa. There seems, however, to be no satisfactory evidence that man

ever enjoyed arboreal life. It is to the strength and sureness of foot that man has been able to maintain and defend much of the civilisation he has acquired. The grasp of the new-born baby's hand gives promise of the power of vigorous offence with any weapon within his clutch; the reflex movements of the foot reveal the capabilities of a future Nimrod, "a mighty hunter before the Lord," which centuries of civilisation have not destroyed.

Malignant Medullary Hypernephroma.

MUCH discussion has centred round the question of the development of renal tumours from adrenal inclusions. A case recently published by Dr. Joseph C. Ohlmacher (*The Journal of Medical Research*, May, 1902) is of much interest, as the author considers it to have arisen from adrenal medulla. The disposition of the reticulum was peculiar, and closely resembled that of the adrenal medulla in the dog. The cells were large and polyhedral, with large faintly-staining nuclei, and a scanty, poorly-staining, vacuolated cytoplasm identical with that of adrenal medullary cells. The widening of the vesicles and blood sinuses was similar to that seen in the adrenal medulla. Embryonic or immature medullary cells beneath the capsule of the tumour penetrated into the deeper portions and presented transition, as is seen in the developing normal adrenal. There were also occasional islands of cylindrical cortical cells having a distinct glomerular arrangement like that, seen in the zona glomerulosa of the horse or dog, and which may be regarded as indicating a reversion to a lower vertebrate type.

Municipal Laboratories.

THE recent controversy between the Town Council and the medical profession of Edinburgh, although in many ways painful, has drawn attention to a most important question. In many large centres like Edinburgh, Manchester, Liverpool, and Leeds, bacteriological examinations and even chemical analyses are undertaken on behalf of the medical officers of health by colleges or professors connected with the special departments. These colleges and members of their staff, we contend, should content themselves with fulfilling their mission in teaching and research. It is not fair to their students or to the profession at large that for the sake of pecuniary advantages they should forego or neglect their particular duties and degrade their position and pathology into a mere business. We consider the only satisfactory escape from this most undesirable condition of affairs is that municipal and county authorities should establish and maintain well-equipped and suitably staffed bacteriological, pathological and chemical laboratories. If such was the case not only would the public generally be benefited and scientific research throughout the country be stimulated, but abundant opportunities would be found for the training and remuneration of many of our younger pathologists. It is often said that pathology does not pay in this country. We fear that such will long continue

to be the case if distinguished pathologists continue to neglect their proper duties in order to make money by superintending the examination of tuberculous sputum, the investigation of throat swabs or the analysis of urine. This matter has for long been a reproach, and the discussions at Edinburgh seem to indicate that if the profession is to maintain its dignity and influence, mere pecuniary advantages of a select few must not be allowed to stand in the way of progress.

The Increasing Consumption of Tea.

STATISTICS and the experience of medical men afford grounds for the opinion that alcoholism is increasing in this country. And now facts and figures are forthcoming to show that the Britisher is becoming a confirmed tea-drinker. According to recently published returns of the Board of Trade, it seems that during the three years, 1898-1900, the consumption of tea has very appreciably increased. From the figures given it appears that in the United Kingdom over 6 lbs. of tea per head of the population is consumed. Sixteen years ago the *per capita* consumption was approximately 5 lb. Now the total amount of tea drunk in the United Kingdom exceeds that of all the other European countries and the United States put together. During the seventeen years from 1884 to 1900 it has risen from 175 million lbs. to 256 millions, an increase of 43 per cent. Of the 6 lb. of tea which is now the estimated yearly *per capita* consumption, little more than one-third of a pound is Chinese, while about 3½ lb. come from India, and 2¼ lb. from Ceylon. All this affords material for the contemplation of the pathologist. There can be no doubt that while tea is a legitimate and most agreeable beverage, it is also capable under certain circumstances, or when taken in excessive quantities, of bringing about functional derangements and initiating or increasing actual morbid processes.

A New Blood Parasite.

A PARASITE found in the blood of a patient suffering from an intermittent form of fever has recently been described. The new vascular intruder belongs to the genus *trypanosoma*, and closely resembles *T. Brucei* in form and staining reactions, but it is decidedly smaller, and in fixed specimens displays a characteristic "set." Nepveu has claimed the discovery of this parasite in man—in Algiers, but his description is so imperfect as to leave his opinion rather doubtful. Mr. J. Everett Dutton described the parasite which he had found in the blood of a European at Bathurst in West Africa. It was present only during the pyrexial periods. Within the last month he has announced the interesting fact of the discovery of this parasite in native children. The symptoms which he had found in his European patient were irregular attacks of fever, with apyrexial intervals. There was also œdema of the eyelids and of the feet, suggestive of some parasitic relationship with the

diseases of horses and cattle known as Nagana and Surra. This discovery opens an immense and important field of investigation and instruction regarding the native diseases of the *developing* Continent.

An Anti-Vaccinist Catastrophe.

A SWANSEA anti-vaccinist has just had reason to reconsider the advantages attending the grant of a certificate of exemption in respect of vaccination. An unvaccinated infant of his contracted small-pox and died, and as the obstinate parent refused to allow her to be removed to an isolation hospital, two other children and the mother subsequently developed the disease. A few cases of this kind—and they are likely to be numerous—could not fail to undermine the obstinacy of all save the irremediably fanatical. When that absurd law was passed we urged that a register should be kept of all exemptions granted, in order that local officers of health might, as far as possible, follow up their history. That this has not been done is a matter for regret, for there can be little doubt that the statistics thus obtained would prove of exceeding value when the Vaccination Acts come up for discussion in 1903.

A GARDEN fête, concert, and variety entertainment, and pastoral play, in aid of the special appeal for St. George's Hospital, London, will be held in the grounds of the Royal Botanic Society, on Tuesday, July 1st.

THE Summer Session of the General Medical Council opened yesterday (27th instant), with the usual presidential address by Sir William Turner, K.C.B.

PERSONAL.

DR. J. H. MOOREHEAD has been elected to the post of Assistant Physician to Sir P. Dun's Hospital.

DR. O'CONNELL, Fethard, co. Tipperary, has been elected to the office of Coroner for the district of South Tipperary.

DR. LITTLE, President of the Ophthalmological Society, will take the chair at a dinner to be given at the Trocadero Restaurant on June 13th.

SIR FREDERICK TREVES will distribute the prizes to the successful students of the Charing Cross Hospital Medical School on June 11th, at 3.30 p.m.

SURGEON-CAPTAIN ARTHUR MARTIN-LEAKE, of the South African Constabulary, has been awarded the Victoria Cross.

PROFESSOR FUCHS, of Vienna, will deliver the Bowman Lecture before the Ophthalmological Society at 4.30 p.m. on June 13th.

THE Duke of Northumberland, Vice-President of the Council of the Sanitary Institute, will preside at the Coronation Dinner which is arranged to take place at the Midland Grand Hotel N.W., on Monday, June 2nd.

PROFESSOR VIRCHOW is now recruiting his health at

Teplitz Schonau, and is gradually recovering the use of his damaged left leg.

THE Earl of Rosebery has been elected Chancellor of the University of London, and Sir Hy. Roscoe, the Vice-Chancellor. Sir Hy. Roscoe has presented a specially-designed silver-gilt mace to the University.

DR. PETER RATTEAY, Dundee, has just been presented with a valuable gold watch from the officers of the Expeditionary Field Forces in West Africa on the occasion of his marriage, he being now in this country on six months' leave.

DR. JAMES A. WHELAN, of Synnot Place, sustained some injuries and a very severe shock by a carriage accident at St. Lawrence Road, Clontarf, on Sunday evening. He was thrown violently to the ground. Mrs. Whelan and a friend of the doctor's happily escaped injury.

Belfast.

[FROM OUR OWN CORRESPONDENT.]

[We are not responsible for opinions expressed by our local correspondents.]

NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.

THE annual meeting of the Ulster Branch of the National Association for the Prevention of Consumption was held on Tuesday, the 20th, in the Town Hall. In the absence of the Lord Mayor, the chair was occupied by Sir Otto Jaffé, J.P., and there was a large attendance, including Dr. Beatty (Manchester) and many of the most prominent medical men in Belfast.

Mr. Robert Brown read the annual report, which emphasised the infective nature of sputum and the necessity of stirring up public opinion to deal with the spitting nuisance. The report stated that Ulster occupies a deplorable position with regard to the prevalence of consumption, its death-rate from this cause per 1,000 being nearly half as much again as in Lancashire, with its crowded manufacturing towns, and being four times as great as the death-rate in the best English county.

In moving the adoption of the report, the Chairman, who is noted for his enlightened views on scientific questions, spoke of the dangers, to children especially, attending the use of unboiled milk. Sir James Haslett, M.P., in seconding the adoption of the report, blamed the damp soil of Belfast. To compare Belfast with London would be an outrage. If they sank a cellar in London they would find the soil as dry as powder, but if they sank to a depth of two feet in Belfast their foundation was filled with water. They might say we should drain Belfast, but it was not so easy draining when so much of the city was under sea level. They could not disinter it, and alter its geographical position. He was delighted to say that though Belfast had increased enormously during the past ten years in population and area, their death-rate from consumption or zymotic disease had not increased but diminished. It was therefore most desirable that they should not take a gloomy view of their city. Though a great deal had yet to be done much had been done already, and when they found that Belfast, the centre of manufactures in Ireland, stood fifth in its death-rate, while Dublin and Cork and other cities were far above it in the number of cases of zymotic disease, he thought it was highly creditable to their community.

The Secretary read a paper by Dr. Niven, medical officer of health, Manchester, describing the steps taken there to combat the spread of consumption, and Dr. Beatty, Dr. Niven's assistant, addressed the meeting. The steps referred to were explained in detail under six heads:—(1) The notification of the existence and address of a consumptive. (2) The education of the public in the character and prevention of the disease,

and especially the education of the patient and his friends. (3) The treatment of his surroundings. (4) Supervision. It was necessary to have some security that the necessary precautions were being carried out. (5) The provision of hospitals for isolation and treatment of the disease. (6) The securing that food, i.e., meat and milk, should be free from the taint of tuberculosis.

Dr. Simpson moved, and Dr. Colwell seconded, a resolution calling on manufacturers to assist in this work by various sanitary precautions in their premises. Professor Whitla moved, and Dr. Darling seconded, a vote of thanks to Dr. Beatty.

The whole proceedings, of which the above is a brief outline, went off exceedingly well, and the meeting can hardly fail to produce good results in Belfast, as a number of the most prominent business men and employers of labour attended.

On Thursday, the 22nd, Dr. Smyth, medical inspector of the Local Government Board, opened a sworn inquiry at the Belfast Union Workhouse into the expenditure on medicines and medical and surgical appliances in the Belfast Workhouse and the several dispensary districts of the Belfast Union for the past half year. Dr. Hall, the senior visiting medical officer, gave some particulars of the daily average number of inmates of the infirmary, which came to about 1,400. He was questioned as to the amount of linseed-meal used, about 43 lbs. daily, which he considered necessary, and not extravagant.

Dr. Jas. Lyness stated that he had been house surgeon from 1893 to 1897, and visiting medical officer since 1899. He described the uses to which some of the drugs were put, and admitted that the quantity of boric acid, 9 cwt. for six months, was large; 1,970 lbs. absorbent cotton were used in the same period, and an average of 82 new bandages daily. The inquiry is not yet terminated.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

NATALITY IN GREAT BRITAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The correspondence to which my first letter on the above-named subject has given origin has been undoubtedly interesting and instructive from several points of view. It has not, however, been at all fully dealt with from the sociological standpoint. What the student of sociology wants to know is whether the baneful spirit of narrow egoism which unquestionably pervades the great bulk of the French nation at the present day has so far permeated the people of our islands that there will follow in Great Britain the national decay which is surely depriving our neighbours of their place among the leading countries of the world. France, with the most fertile soil and the finest climate in Europe—a soil and climate capable of producing enough food to sustain a population of many more millions than now exist—is dying. She has not enough men for her own needs at home, and has none to send to the vast territories, mis-called colonies, which she has latterly acquired in Africa and Asia and Madagascar. In France wealth accumulates and men decay. The evidence as to this is overwhelming, and the effects are clearly to be traced to the one cause—restriction of the growth of population by artificial means. If the example of France is going to be followed and carried to its logical and egoistical conclusion by Great Britain and the other western peoples, Europe will in time (in a few hundred or thousand years) pass into the condition presented by Asia Minor, unless in the meantime the "yellow peril" becomes a reality, and the lands be overrun by prolific swarms overflowing from China and Japan.

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

ADVERTISEMENT AND ALCOHOLISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With regard to the few lines you kindly pub-

lished in your issue, May 14th, in reference to Professor Folet's remarkable statement as to the high percentage of phthisical patients traceable to alcohol! (the statement apparently not being founded on evidence, and therefore calculated to create unnecessary public alarm and prejudice against the legitimate use of alcohol, it would be interesting to learn from scientific sources whether some method could not be devised of testing the action of alcohol on the tuberculous bacilli. Let us suppose for instance, that any given number (the greater the better) of rats or mice were inoculated for tuberculosis and subjected to alcoholic treatment, comparing these with an equal number experimented on without alcohol. I venture to suggest the relative period of existence between these two classes would, to say the least, be a rough indication as to the effect of alcohol on the bacilli.

While I am about it I may be allowed to state that the same error, or, at least, what appears to me to be the same error, on the part of Professor Folet has become the fashion amongst asylum statisticians.

In cases of insanity allied with intemperance these statisticians jump to the conclusion that the intemperance is the cause of the insanity, whereas, as far as evidence is concerned, there is quite as much to show that in numbers of cases it is or may be the effect. Hence these statistics are altogether unreliable and a source of public danger, because it is quite conceivable, in the wear and tear of everyday life in consequence of the high pressure under present unavoidable social conditions, a greater or less number of the public may maintain their nervous equilibrium through a judicious recourse to stimulants, in this sense proving rather a safeguard against insanity than otherwise.

I am, Sir, yours truly,

CLEMENT H. SEES.

Queen's Road, Peckham, S.E.,

Special Articles.

THE MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.

THE nineteenth annual meeting of this Society was held at 11, Chandos Street, W., on May 15th, under the presidency of Dr. de Havilland Hall, Chairman of the Executive Committee.

The Chairman referred to the continued progress of the Society during the previous year. There had been 133 proposals as compared with 114 in the previous year, and there had been twenty-eight proposals for additional benefits as against twenty-two. Though the membership had increased he was thankful to say that the sickness claims had been less than in the previous year, £7,829 10s. as against £8,250. In the Annuity Fund there was a small increase, and a small decrease in the Life Assurance Fund. He suggested that taking out an annuity payable at the age of sixty-five was preferable to extending their sickness limit beyond the age of sixty-five, as had been suggested, because an annuity payable at sixty-five would be a certainty, whereas sickness allowances after that age must necessarily be altogether uncertain. The economy of management of the Society still continued. During the past year the management expenses had been less than 5 per cent. of the premium income as against 10 per cent. which was allowed by the rules. They had put by over £1,000 to the management reserve fund, and they had made the large increase of £1,346 4s. 6d. in their investment reserve fund, which now stood at £7,979 9s. 3d. The total funds of the Society had also grown considerably, viz., from £143,552 11s. 3d. to £154,353 17s. 3d., an increase during the past twelve months of upwards of £10,000.

The votes of the Society in connection with the Royal Medical Benevolent College had this year been given to Gerald MacNaught, the son of a deceased member, and from the position the boy held at the last election he (the Chairman) hoped that the votes would ensure his election into the school at Epsom on this occasion.

He had great pleasure in announcing that Sir

William Church, President of the Royal College of Physicians, had consented to act as arbitrator should they elect him.

The *British Medical Journal* and the *MEDICAL PRESS AND CIRCULAR*, as in past years, had given them most valuable assistance, and the *Medical Examiner*, under the editorship of their secretary, had also been of service in making known the advantages of the society.

The record of Committee attendances would show how well the affairs of the society were looked after by the members of the Committee, and he thought it would be impossible to get a body of men to work more harmoniously than they had done.

The officers for the ensuing year were duly elected, Dr. de Havilland Hall consenting to remain as chairman. The meeting concluded with a cordial vote of thanks to the chairman for the assiduous and conscientious way in which he fulfilled his functions.

THE EPIDEMIC OF SMALL-POX.

THE spread of small-pox in the provinces continues but for the most part the disease occurs in small groups, and the sanitary authorities, though too often hampered by inadequate accommodation or total absence of accommodation, for the victims, are fairly successful in circumscribing the outbreaks. During the past week there has, however, been a serious recrudescence in the metropolis, the total number of admissions having been more than a hundred in excess of that for several weeks previously. The daily average, which had fallen to between 16 and 30, rose again to between 50 and 65, a phenomenon not very easy to account for. In accordance with past experience the advent of warmer weather is likely to be followed—after the lapse of a week or ten days—by a marked and persistent fall in the number of the newly infected but, on the other hand, the epidemic will probably smoulder on through the summer, with the prospect of a recrudescence so soon as climatic conditions once more favour a renewal of activity.

Lunacy Department.

ASYLUM REPORTS.

Worcester County.—This report is voluminous, but of no very special interest. The rate of board has not been increased, and this speaks well for the management. The Commissioners' Report, on the whole, is very satisfactory, but they consider the infirmaries in the main building are very inconvenient and inadequate for the treating of symptomatic disease. The attendants and nurses have practically no recreation-rooms. Fifty-two nurses have the use of a room, not more than sufficient for six, and the men are even worse off, as they have no room at all. Can the Committee have realised this? The relaxation of attendants and nurses ought to be considered as well as the recreation of the patients. The social factor in an asylum is one of great importance. The death-rate, the highest for fourteen years, was 11·18 per cent., and the recovery rate 32·76 per cent. Pneumonia and phthisis were each responsible for 20 per cent. of the deaths.

Warneford.—This mental hospital, intended for the care and treatment of patients belonging to the upper and middle classes, is healthily situated on a hill near Oxford. The report is well got up and includes some splendid photos of the buildings and grounds. The usual routine has been satisfactorily carried out. The regular terms of admission are two guineas a week, but idiots, epileptics, and paralytics are not eligible. The Committee report: "The prosperity of the hospital has continued to improve, and in all respects the year 1901 has been in advance on previous years." Undoubtedly this indicates a very satisfactory state of affairs. Attendants and nurses who gain the nursing certificate have their wages increased £1 per annum. The recovery rate was high—50 per cent. of the admissions—very gratifying results.

Northampton County.—The Committee have been considering the question of making provision for the proper

treatment and isolation of tuberculosis. This is a step in the right direction, as strong measures are required to cope with this fell disease. We hope yet to see a sanatorium for this purpose established in connection with every asylum. The rate of board, although raised to 8s. per week, is still low. The dietary scale is generous, but there is a want of variety. Of the men only thirty are employed at farm or garden work. This is much to be regretted, as idleness and routine walking exercise are most depressing and enervating for patients and officials alike. Of those admitted 21 per cent. were over the age of sixty, but nevertheless the recovery rate was 30.43 per cent. As a cause of insanity heredity appears in 37 per cent. of the cases. We are surprised to learn from the Commissioners' Report, which is very favourable, that there is no pathological laboratory. Without it an asylum, nowadays, is not considered fully equipped.

Burntwood.—Dr. Spence reports that the year has been an uneventful one. The admissions show a steady increase, the recovery rate is rather below the average, and the death-rate somewhat high. Alcohol was the cause of insanity in fully 7 per cent. of the admissions.

Cheddleton.—The second annual report is interesting, and gives evidence of push and energy in the management, and considerable progress has been made in its development. The recovery rate is very small and the death-rate is rather high. There were five deaths from or complicated by colitis, out of no fewer than twenty-nine cases. It is rather strange to find an epidemic of colitis breaking out in an asylum so recently opened. A high percentage of men and women are usefully employed, and we are glad to see this. The rate of board has fallen from 17s.—a very high rate—to 10s. 8d. per week, and it will, in all likelihood, be yet much reduced. There is abundant evidence that Dr. Menzies means to greatly reduce the expenditure, paid labour being largely dispensed with. The Commissioners in their report refer to a new feature in asylum management, viz., the establishment of a canteen on the male side where the male attendants who do not have beer or beer money, may obtain beer and other things to a limited amount after their hours of duty. We wonder what comes under the head of "other things." This new feature is objectionable under any conditions, and cannot possibly have a good effect on the social status. We shall watch with interest the results of this, as well as his other new ventures in asylum management, on which we must congratulate him. We appreciate all legitimate efforts to depart from the usual trend, for by such we advance.

Aberdeen Royal.—There were 929 patients on the register at December 31st last, as compared with 887 on the same date twelve months prior. The admissions during the year numbered 262, the discharges 161, and the deaths fifty-nine. Of those admitted sixty-five were private, and 197 were pauper patients; twelve were over 70, and three were only 15 years of age. The assigned cause of insanity was heredity predisposition in sixty-six cases, and intemperance in forty cases. The recovery rate was 46 per cent. on the admissions, and the death-rate 6.5 per cent. Both these rates may be regarded as satisfactory. The two new blocks added to the hospital have proved of much value and the Commissioners in their reports speak highly of them and the excellence of the accommodation they provide. The reports of the Commissioners are very satisfactory, and it is evident the management is in capable hands.

Isle of Man.—The Board reports the condition of the asylum continues satisfactory, and that the accommodation in all respects is sufficient. The number of residents continues to increase, and the average number for the past year, 207, is a record one. We note with approval the Board propose to build two additional cottages for married attendants. The recovery rate is satisfactory—48 per cent. of the admissions—but the death-rate is rather high—9.1 per cent. Owing to extensive ordinary repairs and renewals during the year, the mortuary and post-mortem room have not yet been completed. The principal assigned cause of insanity is alcohol. It is responsible for 30 per cent. of the ad-

missions. The average cost of maintenance per week per head was 7s. 7d. The report is full of detail, and the management continues efficient.

Obituary.

WILLIAM MILLER ORD, M.D., F.R.C.P. LOND.

THE death of Dr. William Miller Ord, which, as we briefly announced last week, took place on the 14th inst., marks the termination of a very successful and laborious career.

Dr. Ord was the eldest son of Mr. Ord, who had a large practice at Streatham. He was educated at King's College, and took the degree of M.B. London in 1857, after a brilliant career at St. Thomas's Hospital, to which institution he became house surgeon and subsequently surgical registrar. Circumstances at that time obliged him to go into general practice and for some years he assisted his father at Streatham, an experience which he always asserted proved of the greatest possible service to him. After some years he was appointed lecturer on zoology at St. Thomas's Hospital. In 1869 he was admitted to the membership of the Royal College of Physicians, and two years subsequently, the hospital having meanwhile been removed to its present site, he was elected assistant physician. He occupied successively the lectureship on physiology and that of medicine, succeeding the famed Dr. Murchison.

His selection as dean of the medical school marked an epoch in its history. For some years the affairs of the school had been languishing, but under Dr. Ord's rule it rapidly made headway and attained a position in the medical world which it had never previously reached, the progress being in no small degree due to his personal influence and intelligent direction.

In 1875 he was elected a Fellow of the College of Physicians, and a year or two later he became full physician to his hospital. Dr. Ord was a born teacher, of genial manners and urbane wit, attentive to his work, and mindful of the responsibilities he had assumed. His capacity for work was immense, and he led the busiest possible life for some fifteen years. He resigned the post of physician in 1896, having relinquished the lectureship on medicine in 1894. He was appointed consulting physician in due course, and he never ceased to take the greatest interest in the hospital and school.

Dr. Ord's name will perhaps be best remembered in connection with the important work which he carried out in elucidating the clinical future of the then new disease, myxodema. He was secretary to the Committee of the Clinical Society appointed to investigate the disease, and his researches were conducted with such care and completeness that his writings on the subject really left little to be added. It is to Dr. Ord, indeed, that we owe the designation "myxodema," which has been universally accepted. Another remarkable series of investigations bore fruit in a paper on "The Influence of Colloids on Crystalline Forms and Cohesions," which fully explained the varying forms of crystals which fall in urinary sediments. Dr. Ord also devoted an immense amount of labour to the compilation of the "Nomenclature of Diseases"—a task assumed by the Royal College of Physicians. This work will remain as a lasting monument of skill and comprehensiveness in classification.

Dr. Ord's health began to fail some three years ago, after repeated attacks of influenza, but he continued to practise. His health, however, steadily declined, until about two years ago, when he relinquished active work and retired to Hurstbourne Tarrant, near Andover. He led a quiet, enjoyable existence amid his books and the attractions of a country life, but a few weeks ago brain failure began to manifest itself, and he was taken to the residence of his son at Salisbury, where he died.

PROFESSOR D. J. CUNNINGHAM, F.R.S., has been invited by the Council of the Anthropological Institute to deliver the Huxley Memorial Lecture for 1902. This invitation carries with it the Huxley Memorial Medal.

Literature.

DELAFIELD'S PATHOLOGICAL ANATOMY AND HISTOLOGY. (a)

THIS portly volume of upwards of 800 pages affords striking evidence of the progress which has been, and is still being, accomplished in medical literature on the other side of the ocean. The work compares favourably with even the best known text-books by English authors, and is free from what, to British readers, will always be accounted a blemish, viz., attempts at the phonetic spelling of familiar technical words. It is copiously illustrated; there are no less than thirteen full-page plates and 453 figures in black and colours, in the production whereof the art of photography has been turned to excellent account.

The volume is divided into three parts. The first describes the technique of post-mortem examinations and the appearances in certain forms of death from violence, together with directions for the preservation of pathological specimens and their preparation for subsequent investigation.

Part 2 deals with general pathology and the method of classification, which differs in many respects from that usually followed, has much to commend it. Starting with morbid changes in the circulation, we are led to the study of atrophy, pigmentary and other degenerations, and necrosis, and their antitheses, hypertrophy and regeneration.

Coming to the subject of inflammation, which hitherto it has been customary to describe under its clinical aspects—*calor, rubor, dolor, tumor*—the authors are fain to confess that the processes and structural alterations embraced in the conception of inflammation have become so varied and complex that a definition or even a characterisation is not merely difficult, but is virtually impossible. We are reduced, therefore, to consider the more typical of the phenomena and lesions which are commonly grouped under the term inflammation. So be it. It is certainly better to have no definition at all rather than one which is merely clinical (and is therefore out of place in a treatise on pathology) or one which obviously fails to furnish a comprehensive formula for the condition.

After dealing with animal and vegetable parasites the authors proceed to discuss the relations of micro-organisms to disease, comprising the phenomena of infection and immunity. We may note *en passant* that the authors appear to adopt the view that there is no essential difference between tuberculosis in man and the disease as it affects animals, and they boldly adhere to the view that the bacilli may be introduced into the human organism by contaminated meat and by the meat of tuberculous animals. This chapter no doubt was written, possibly even printed, before Koch startled the scientific world by his distinctive hypothesis, otherwise we imagine the authors would have "hedged" a little in anticipation of possible modifications in the manner of regarding tuberculous infection. The views enumerated by the authors are, after all, those upon which sanitary officers still base their action, indeed, they still hold the field in the absence of conclusive evidence to the contrary which, under the circumstances, it will be difficult to obtain.

Part 3 is devoted to special pathology, that is, the pathology of special organs. It occupies the greater part of the volume and calls for no remark beyond the fact that the subject is treated with great thoroughness.

The volume testifies to much careful work and in this edition various lectures have been revised or re-written to bring them in line with recent additions to our knowledge, notably the sections on the blood and on the normal morphology, degenerations and inflammation of the nervous system.

Mitchell Prudden, M.D., LL.D., Professor of Pathology, Columbia University, &c. Sixth Edition. Price 21s. London: Baillière, Tindall and Cox.

HUGHES'S PRACTICAL ANATOMY. (a)

THE pleasure of reviewing this, Part I. of what promises to be an admirable anatomical guide both to the student and to the surgeon is very much damped by having to refer to the author as the late Professor Hughes, and the consideration of the immense loss the whole profession has sustained by his death at the early age of thirty-nine from fever contracted in the service of his country. However, it is but fair to say that his intentions could hardly have been carried out in a more efficient manner than has been done by Dr. Keith. One of the first things that strike the reader of this work is the excellent directions which are given to the student as to the mode of dissection, these being supplemented by some useful indications as to how in dissecting one part of the human body he may be aided by a possibly more advanced dissector who is manipulating a contiguous part. It is apparent, however, that the work is certainly not intended for the beginner, who, we should imagine, would be puzzled at having his attention drawn at once and at the same time to superficial and deep fascia, nerves, arteries, lymphatics, veins, &c., coincidentally with muscles. On the other hand, to the more advanced student or to the surgeon this book should prove invaluable, as with the aid of the text and of the very clear illustrations, one is able to follow step by step during a dissection every structure as it is uncovered. Part I., which we now have under consideration, deals with the upper and lower extremities. With regard to the upper extremity we think it a very good practice, as is here laid down, to begin the dissection with the dorsal region of this part of the body, and to study the trapezius, the latissimus dorsi, the rhomboidei, and the levator anguli scapulae, together with their superficial coverings, vessels, nerves, &c., the body lying face downwards on the table till the time has arrived for the dissection of the chest and arm, when it is turned over on its back. The description of the axilla is most practical and lucid, being much helped by some capital plates and figures; the same, indeed, may be said of the whole of the work, the large majority of the coloured plates having been prepared under the author's supervision by Mr. Prendergast Parker, the remainder being taken from Holden's "Osteology." Space will not allow any lengthy reference to the former, which number thirty, but we may mention that we were specially struck by Plate V. (three sections showing the relationship of the brachial artery, a in the middle third, b in the lower third of the arm, and c in the antecubital space), and by Plate XIX. (diagrammatic section of the popliteal space, condyles of the femur and patella). With regard to the 266 figures, the ones that specially draw our attention are: Fig. 48 (diagram to show the termination of extensor tendons on a digit, H. Balean), Fig. 58 (showing the surface markings of the gluteal region, H. Balean), Fig. 64 (showing the structures which form and those which pass through the sacro-sciatic foramina, H. Balean), Fig. 84 (section of the thigh showing the formation of Hunter's canal, Anderson). It is, however, impossible in these few words to do justice to such a work, but we must say that we look forward with more than ordinary satisfaction to the appearance of Parts II. and III.

CHEADLE ON ARTIFICIAL FEEDING. (b)

THIS, the fifth edition, of a work which has deservedly attained a wide popularity, has been edited by Dr. Poynton, of the Great Ormond Street Hospital for Sick Children, who has revised it and brought it up to the standard of the times. This is no mere "guide to infants' diet." It is cast in the form of lectures, and is characterised by a certain amount of verbiage in-

(a) "Manual of Practical Anatomy." By the late Prof. A. W. Hughes, M.B., M.C., F.R.C.S. Edited and completed by Arthur Keith, M.D., F.R.C.S., in three parts. Part I. "The Upper and Lower Extremities." Pp. 267. London: J. and A. Churchill.

(b) "Artificial Feeding and Food Disorders of Infants." By W. B. Cheadle, M.A., M.D. Cantab., F.R.C.P., Senior Physician to St. Mary's Hospital, &c., &c. Fifth Edition. London: Smith, Elder, and Co. 1902. Price 5s.

separable from this style of composition. Some forty pages are allotted to the fundamental physiological principles of infant nutrition, and then the "gentlemen," who are so frequently referred to, are invited to consider the question of artificial foods, this term being used to designate all substitutes for the maternal supply. After discussing the various methods of minimising the drawbacks attending the use of cows' milk, the author criticises the various artificial foods, properly so-called, especially malted foods which, he tells us, "are to be regarded as a means of supplying an additional amount of carbohydrates and some additional proteid . . . they are admirable in proportion to the amount of nitrogenous matter they contain, and in proportion to the conversion of the starch through some of the stages into sugar." And we are warned against the dangers attending the too exclusive use of such foods—scurvy, rickets, &c. The rest of the book is devoted to the treatment of special diseased conditions. We have nothing but praise for the work as a whole, only we could wish that a more concentrated style had been employed.

SELECTED ESSAYS AND MONOGRAPHS. (a)

THE present volume of the Sydenham Society's publications will be found to be of particular interest, as it contains several of the many short monographs—written by our countrymen—which have become of an almost historical importance. Notable among them, are a selection of four papers by the late Dr. Braxton Hicks on obstetrical subjects. The last of these is that in which he presented to the British Medical Association in 1889, the now almost universally adopted treatment of placenta prævia, a treatment which has been mainly responsible for reducing the mortality of this condition from 30 to 50 per cent. to less than 5 per cent. Dr. Cullingworth has added a short notice of Braxton Hicks's life and work, and a most valuable list of his published writings. We are sorry that the Editors had not the space to include in the volume before us his paper on "Combined External and Internal Version."

Of the remaining monographs those of most interest are, perhaps, Hodgkin "On Some Morbid Appearances of the Absorbent Glands and Spleen" and Paget "On Chronic Inflammation of Bones." A monograph on "Danish Lazar Houses in the Middle Ages," by Dr. Edward Ehlers, constitutes the only foreign contribution to a most interesting volume.

The work before us is, probably, the last of its kind which the Society will publish for some years, as it has been decided that during the next five years it will devote its funds almost exclusively to the publication of a Clinical Atlas of Illustrations of Disease. Such an Atlas will be most popular, and the fact that it is forthcoming will undoubtedly prove an inducement to medical men to join a Society to which so little is given and from which so much is received.

A RETROSPECT OF SURGERY. (b)

THIS small book is the Hunterian Lecture of the Hunterian Society, 1901, and should be interesting reading to any operating surgeon, as it takes us from the days of Percival Pott and Hunter to the present time, presenting in very graphic language the various improvements which have taken place in the science and art of surgery during the past century. In speaking of anaesthetics the author gives in the words of Mr. Cadge a capital description of the first operation performed by Liston under ether. Among other matters the advances in abdominal and brain surgery are fully discussed, together with the various methods in operating for the radical cure of hernia and the improvements in ophthalmic surgery, but Mr. Poland does not think that the manipulative part of our profession has progressed as it should have done since John Hunter's days. After referring to and dwell

ling on the employment of the X-rays especially in fractures, Mr. Poland writes hopefully of the onward march of surgery he expects for the twentieth century, finishing with Byron's words: "The best of prophets of the future is the past."

PRACTICAL MEDICINE. (a)

THAT this work should so soon have reached a third edition is evidence that its practical contributions are appreciated in the profession. Much is said and quoted on the nature and cure of insomnia, but we doubt if any better theory as to the cause of sleep can be found than that which the author and also Sir Lauder Brunton suggest in "the drowning our cerebral cells in a kind of auto-intoxication with the ashes of our waking fires." The plans for treatment accord well with this reasonable hypothesis.

The short chapter on the cure of gastralgia gives useful hints on the diagnosis of this very common complaint. In small doses (gr. $\frac{1}{4}$ th) of arsenious acid the author, like many others, finds a trustworthy remedy.

The treatment of hæmorrhoids by the application of the unguentum ranunculicarum seems novel as well as useful. We believe this remedy is, however, recommended in Gerard's Herbal. "Celandine Cerate" is an elegant name for the ointment suggested by Sir James.

Chloride of calcium still stands well with the author as his favourite general drug in pulmonary consumption. We entirely agree with him in the use of this salt, and also the calcium hypophosphite. Both agree well with the stomach, and tend to prevent pulmonary hæmorrhage and diarrhoea. After some short chapters on eczema, inhalations for asthma, and a few other therapeutic matters, all worth the notice of the practical physician, the book finishes with a table of diet for diabetic patients. The table is a liberal one, but we fail to see why such articles of food as broccoli, cauliflowers, French beans, and macaroni should be withheld. This last has always seemed to us a sort of gluten food by no means bad in diabetes.

The table, however, must be accepted as coming from one of good practical experience.

Medical News.

The Medical Temperance Association.

THE twenty-sixth annual meeting of this association was held at the rooms of the Royal Medical and Chirurgical Society, 20, Hanover Square, on Tuesday, May 20th. There was a reception, with refreshments and opportunity for the inspection of microscopic specimens, lantern slides, photographs, and diagrams lent by the president (Mr. Eccles), Mr. Pernet, and Dr. Kelynaek. Professor Sims Woodhead took the chair at the meeting which followed. The annual report was read by the honorary secretary, Dr. J. J. Ridge, in which it was stated that there were at present 520 members and 438 student-associates. Meetings of medical students had been held at the London, Guy's, and St. Thomas's hospitals, and the *Medical Temperance Review* had been widely circulated. An international medical manifesto condemning the use of alcoholic beverages on physiological grounds, had been prepared in conjunction with the American Medical Temperance Association and the Association of the German-speaking Abstaining-Physicians. This was being extensively signed at home and abroad. The funds of the association were low, and there would have been a deficit but for an opportune legacy of £250. An interesting and valuable address was then given by Mr. McAdam Eccles on "Cirrhosis of the Liver and its Causation by Alcohol and Otherwise," illustrated by lantern views. A discussion ensued in which Drs. R. Paramore, A. B. Olsen, T. Morton, Heywood Smith, T. Rushbrook, and J. J. Ridge took

(a) "Selected Essays and Monographs, chiefly from English Sources, Braxton Hicks, Bodington, Hodgkin, Paget, Humphry, Ehlers." London: The New Sydenham Society, 1901. Pp. 325, with several plates. London: H. K. Lewis.

(b) "A Retrospect of Surgery during the Past Century." By John Poland, F.R.C.S. London: Smith, Elder and Co.

(a) "Contributions to Practical Medicine." By Sir James Sawyer, M.D., F.R.C.P. Lond., Senior Consulting Physician to the Queen's Hospital, and late Professor of Medicine, Therapeutics and Pathology in the Queen's College; Physician to the Birmingham Hospital for Sick Children, &c. Third Edition, revised and enlarged. Birmingham: Cornish Brothers. 1902.

part, and a vote of thanks was unanimously accorded to the reader of the paper.

Royal College of Physicians of London and the Royal Procession.

WE are glad to see that the abode of medicine in Pall Mall East is to be made available for Fellows and Members of the College of Physicians on the occasion of the forthcoming procession. The Fellows naturally receive first attention, but it has been decided to issue also to Members of the College tickets for places to view the Royal Procession from the College, on June 27th, to the number of 150. Not more than two tickets will be issued to any one member. These tickets will be available only for himself and a lady member of his family. The distribution will be by ballot under the direction of the committee.

Cocaine Poisoning.

AN inquest was held by Dr. G. Danford Thomas, on the 20th inst., at Holborn, on Mr. William Arthur Stradling, M.B.C.S., aged 49, who was found dead in his bedroom at High Holborn. According to the widow, who was living apart from her husband at Tunbridge Wells, he suffered from sciatica as the result of an accident, and was in the habit of injecting cocaine to assuage the pain and procure sleep. He had not followed his profession lately. Medical evidence showed that death was due to cocaine poisoning. A verdict of death by misadventure was returned.

Suicide of a London Practitioner.

MR. WILLIAM HEALY, L.R.C.P. & S., of Gower Street, W.C., committed suicide last week by jumping overboard from the ss. *Scotia* on approaching Dublin Bay. The deceased had been in ill-health for some time, and had suffered much from headache and insomnia, but nothing had transpired to suggest the possibility of any suicidal proclivities.

Medical and Hygienic Exhibition.

THIS annual exhibition was held at the Queen's Hall, Langham Place, W., last week, but a visit to the various exhibits tended to convey the impression that it is not gaining in favour with the various trades cognate to the healing art. There was no scarcity of visitors, most of whom, however, belonged to the nursing sisterhood, and they came away heavily laden with spoils in the shape of samples and literature. There is certainly scope for an annual exhibition of this kind, but to be of service to medical men it is indispensable that the best known firms of manufacturers of medical, surgical, and hygienic objects and apparatus should associate themselves therewith, whereas they, or many among them, for some reason hold aloof.

Otological Society of the United Kingdom.

A MEETING of the Otological Society of the United Kingdom will take place in the Anatomical Department of the Medical School of Trinity College on Saturday, May 31st, at 11 o'clock a.m. The Council of the Society hopes that the meeting will be attended by a large number of the Fellows of the Royal Academy of Medicine in Ireland, who are invited to be present and to bring with them other members of the medical profession who may be interested in the subject matter of the meeting.

Society for Relief of Widows and Orphans of Medical Men.

THE annual general meeting of the Society was held in the rooms of the Medical Society on Wednesday last, May 21st, the President, Mr. Christopher Heath, being in the chair. From the report read by the Secretary it appeared thirty-five new members were elected during 1901, fourteen had died, and two elections had been declared void; 299 members were on the books at the end of the year, an increase of nineteen. Six fresh applications for grants had been received from widows and grants given, two had died, leaving fifty-one widows in receipt of grants. Three orphans had been elected, two had become ineligible, fourteen still remained for assistance. The receipts available for grants and expenses had been £3,409 7s. 6d., and the grants and expenses £3,397 6s. 2d. A donation of £200 had been received from the executors of Miss C. A. Birch. During the year Mr. Upton resigned the office of honorary solicitor, which had been held by his father and

grandfather. The directors passed a vote of thanks to Mr. Upton for his long and valuable services, and had since heard of his death with great regret. Mr. H. G. Tudor was elected an honorary member. Mr. Tudor's family have acted as brokers since the foundation of the Society, and have always given their services gratis. A vote of thanks to the Editors of the Medical Journals for their ready help in making known the objects of the Society was passed. The following were elected to fill the vacancies in the Court of Directors:—Mr. Debenham, Mr. Crozier, Dr. Constable, Dr. Pope, Dr. de H. Hall, Mr. Canton, Dr. Crabb, Mr. Kiallmark, and Mr. Scanes Spicer. A letter was read from Dr. Robert Barnes, enclosing a donation of £100, and a cordial vote of thanks was accorded him. A vote of thanks to the Chairman closed the business of the meeting.

Royal College of Surgeons, Ireland.

THE annual meeting of the Fellows of the College will be held on Saturday next, in the College. The annual election of the President, Vice-president, and Council will take place on Monday next, the 2nd prox. The following candidates offer themselves for election:—For President, L. H. Ormsby; for Vice-president, J. J. Cranny, A. Chance; for Secretary of the College, Sir C. Cameron, C.B.; for Council, (19 seats) *E. H. Bennett, *Sir P. C. Smyly, *H. R. Swanzy, *Sir W. Thomson, *A. Meldon, *Sir C. Cameron, J. D. Hillis, *R. D. Purefoy, *H. G. Sherlock, *C. B. Ball, *J. B. Story, *T. Miles, *J. Lentaigne, T. Donnelly, F. T. P. Newell, *R. H. Woods, *E. B. McCausland, J. D. McFeely, A. J. M. Blaney, W. Taylor, H. W. Oulton, T. O'C. Redmond. Those marked (*) are members of the out-going council, who offer themselves for re-election.

Pass Lists.

Royal College of Surgeons, Ireland.—Fellowship Examination.

THE following candidates having passed the necessary examination, have been admitted Fellows of the College:—Miss C. M'Crea, Mr. R. D. Patterson, Mr. R. S. Ryce, Mr. M. J. Smith, and Mr. D. Turner. The following passed the primary part of the examination:—Mr. P. Maher and Miss M. Thorne.

Royal College of Surgeons, Edinburgh.

AT a meeting of the Council on May 16th the following gentlemen, having passed the necessary examinations, were admitted Fellows of the College:—William John Barclay, M.B., Ch.B., Frederick William Collinson, M.D., M.R.C.S. Eng., David Ewart, M.B., Ch.B., Charles Forsyth, M.B., Ch.B., Henry Albert John Gidney, L.S.A., John Holroyde, L.S.A., M.R.C.S. Eng., John Jeffrey, M.B., Ch.B., Thomas Davy Luke, M.B., Ch.B., Charles Henry Leet Palk, M.B., C.M., and Charles Henry James Watson, M.B., Ch.B. At the same meeting the medal and set of books forming the Bathgate Memorial Prize, presented to the College by Colonel William Lorimer Bathgate, in memory of his late father, William M'Pherne Bathgate, Fellow of the College, was awarded to Miss Charlotte Rose Greenfield, of Edinburgh, for the highest marks obtained in competitive examination in materia medica and therapeutics.

Society of Apothecaries of London.

THE following candidates passed during the May examination in—

Surgery.—F. G. Bennett (Sections I. and II.), J. C. O. Bradbury (Sections I. and II.), G. F. G. de Laubenque, H. F. B. Roberts (Sections I. and II.), B. Rowlands, P. P. Tobit (Section II.).

Medicine.—J. H. Clements, E. Gray, W. P. A. Hardwicke, G. A. Jones (Sections I. and II.), F. I. M. Jupe, E. J. Miller, H. F. B. Roberts (Sections I. and II.), F. H. Rotherham, C. M. Woods (Section I.).

Forensic Medicine.—E. Gray, G. A. Jones, F. I. M. Jupe, E. J. Miller, F. H. Rotherham, C. M. Woods.

Midwifery.—G. A. Crowe, G. A. Jones, F. H. Hand. The L.S.A. diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—J. H. Clements, W. P. A. Hardwicke, F. I. M. Jupe, G. F. G. de Laubenque, B. Rowlands, and P. P. Tobit.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DIABETIC COOKERY.

WOULD you or some of your readers kindly inform me if there is a good work published on cookery for diabetic patients, including a full list of the vegetables and fruits that may be used, the publishers from whom it may be obtained, and price?—**ANCESTILL.**

McK. R.—We cannot discuss the policy of our contemporaries in such a matter as that complained of. Possibly a personal interview with the Editor would establish the facts in the light in which you place them before us.

'THE POLICE AND A "CAUSE CELEBRE"'

PROCEEDINGS of considerable interest to pharmacists are pending at the Thames Police Court, where Mr. Glyn Jones is contesting the obligation to pay medicine stamp duty on ammoniated tincture of quinine merely because certain clauses are printed on the label in respect of its therapeutic effects. An amusing incident is related in the *Chemist and Druggist* from a litigant who, after waiting from two to near four o'clock for his case to be called, turned despairingly to a policeman and said, "What's it all about?" "Well," said the Bobby, "at one time I thought they were squabbling about three-ha'pence on a box of quinine pills, but blest if I place it now!" "Gad," said the first, "if I'd known it I'd 'ave paid the blamed three-ha'pence myself."

G.S.A.—We are unable to find that any edition has been published since 1894, but it is just possible that the author may have changed publishers. The simplest plan would be to address the author direct should your bookseller be unable to obtain the required information.

CARNIVOROUS PLANTS AND FLOWERS.

THE thrilling discovery of a new carnivorous plant has recently been made by Dunstan, on the shores of Lake Nicaragua. As this accomplished naturalist was walking with his dog, his attention was suddenly attracted by the cries of pain and terror of the latter—who had lingered a little behind to explore—and hastening to the rescue he found the animal held fast by three sticky bands, which had chafed the skin to bleeding. The bands in question were formed by the branches of a carnivorous plant, which has since been named by the discoverer the "land octopus." He describes the branches as of a polished black colour, without leaves, secreting a viscid fluid, and furnished with suckers by which they attach themselves with extreme tenacity. It might, in fact, be almost believed, without special effort of the imagination, to be an octopus transformed into a plant. This uncanny product of the vegetable kingdom is denominated by the inhabitants of that country "the devil's noose." The moth-catching plant (*Araucaria albens*) is a native of Central Africa. It was accidentally introduced into Australia a few years ago, and its growth has since been encouraged, as it was found efficacious in the destruction of moths. The calyx is deep, and its base is furnished with sweet juices. The moth is attracted by the contents, and protrudes its proboscis, which is immediately nipped by the two strong, hard, black pincers which guard the passage. Once caught there is no escape, the imprisoned creature invariably perishes miserably.

ROYAL COLLEGE OF SURGEONS.—Election of President, Vice-President, and Council.

TUESDAY, JUNE 3RD.

DUBLIN UNIVERSITY.—Final Medical Examination in Midwifery. Diploma in Public Health Examination (first part).

Appointments.

BRAND, W. H. EDEN, L.R.C.S. & L.R.C.P. Edin., House Surgeon to the Northern Infirmary, Inverness.

BROWNLEE, ALEX., L.R.C.P. & S. Edin., L.D.S. Edin., Assistant House Physician to the Infirmary, Cardiff.

CLAYTON-GREENE, W. H., B.A., M.B., B.C. Cantab., F.R.C.S. Eng., Surgical Registrar to St. Mary's Hospital.

DEGRUCHY, C. W., M.R.C.S., L.R.C.P. Lond., Medical Officer of Health to the Carleton Urban District Council.

HARRIS, JOHN HENRY, M.D. Durh., M.R.C.S., L.S.A., D.P.H. Cantab., Medical Officer of Health for the Dartmouth Port Sanitary Authority.

HEFFERNAN, PATRICK, L.R.C.P., L.R.C.S. Edin., Assistant Medical Officer of Clonmel Asylum.

HOWARD, WILFRID, L.R.C.P. Edin., M.R.C.S., District Medical Officer for the parishes of New and Old Buckenham, and also Public Vaccinator for the same parishes.

HYDE, EDWIN, M.R.C.S., L.R.C.P. Lond., Assistant House Surgeon to the Infirmary, Cardiff.

THOMSON, W. ERNEST, M.A., M.D., Surgeon to the Glasgow Eye Infirmary.

TRYNE, WILLIAM, M.A., M.D. Edin., Medical Superintendent to the Isolation Hospital for the Barnet Urban District.

Vacancies.

Barrington's Hospital.—Matron. Salary £60 per annum, with board, apartments, and laundry. Applications to the Registrar. (See Advt.)

Cardiff Union.—Assistant Medical Officer. Salary £130 per annum, with rations, apartments, attendance, and washing. Applications immediately to Arthur J. Harris, Clerk, Union Offices, Queen's Chambers, Cardiff.

Cheshire County Asylum, Macclesfield.—Temporary Assistant Medical Officer during the months of July, August, and September. Salary £4 4s. per week. Apply to the Medical Superintendent.

City and County of Canterbury Borough Asylum.—Medical Superintendent. Salary £350 per annum, with unfurnished house, lighting, washing for himself and family, and produce of garden. Applications to Henry Fielding, Town Clerk's Office, 15, Burgate Street, Canterbury.

County Asylum, Whittingham, Lancashire.—Junior Assistant Medical Officer. Salary £150. Furnished apartments, board, washing, and attendance provided. Applications to the Medical Superintendent.

Durham County Asylum.—Third Assistant Medical Officer. Salary £150, with apartments, board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Hereford County and City Asylum.—Senior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications immediately to the Medical Superintendent.

Sir Patrick's Dun's Hospital, Lady Superintendent. Salary £125 per annum, with furnished apartments, laundry and attendance. Applications to the Secretary of Medical Board. (See Advt.)

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board (except beer, spirits, &c.), fuel, lighting, and washing. Applications to the Medical Superintendent.

St. Mary's Hospital for Sick Children, Plaistow, E.—Resident Medical Officer. Salary £80 per annum, with board, residence, and laundry. Applications to Percy J. Glenton, Secretary.

The Throat Hospital, Golden Square, W.—Junior House Surgeon.—Salary £100 per annum, with lunch daily. Applications to W. Holt, Secy. Supt.

Births.

DYBALL.—On May 30th, at 47, Queen Street, Exeter, the wife of Brennan Dyball, F.R.C.S., of a daughter.

HUGHES.—On May 30th at Springfield, Anerley, S.E., the wife of Staff Surgeon Hughes, Royal Navy, H.M.S. *Crisier*, of a son.

WILLOUGHBY.—On May 22nd, at 2, Cumberland Villas, Gravesend, the wife of W. M. Willoughby, B.A., M.B., D.P.H. Camb., of a son.

Marriage.

HUNGERFORD—ELLIOT.—On May 24th, at the Parish Church, Chiswick, Wm. Alex. Hungerford, eldest son of Deputy Surgeon-General Richard Hungerford, of Chiswick, to Dorothy Noyes, daughter of Henry Francis Elliot, F.R.C.S.E., of Chiswick.

ASSOCIATED EPIDEMICS.

By DR. V. BABES,

Professor at the Faculty of Medicine of Bucharest.

[SPECIALLY TRANSLATED FOR THE MEDICAL PRESS AND CIRCULAR.]

OUR knowledge of the real nature of epidemics and their causes is still rather vague; in truth, we have come to regard them as morbid entities, each one possessing its special microbe, and this not only in regard to those which attack persons in the enjoyment of good health, but also in certain kinds of epidemics occurring in hospitals, such as epidemics of erysipelas, hospital gangrene, &c. In 1895 I drew attention, at the French Medical Congress at Bordeaux, to certain hospital epidemics with a high mortality which could not be shown to possess any specific pathogenic elements, those being merely the ordinary pyogenic organisms, which had, however, acquired a very marked increase of virulence. They attack subjects already suffering from one or other of the various infectious or debilitating diseases, and on this predisposed soil the staphylococcus aureus, the streptococcus and a saprogenous micro-organism, alone or in association, establish a footing. We propose to classify them under the heading of "Hospital Epidemics of Associated Diseases."

In these instances we are dealing with a disease which becomes epidemic through its association with a secondary infection, although neither of them, alone, is of an epidemic character.

We had, moreover, previously observed and mentioned epidemic streptococcal infections displaying the characteristics of hæmorrhagic septicæmia, and generally following on exanthematous affections, such as scarlatina. The streptococcus, which is nearly always present in the subjects of scarlatina, assumes special and exaggerated virulence, which is shown by the tendency to hæmorrhage and the high mortality.

With regard to the enhanced virulence of the common germs, the factors in its production are multiple and indeterminate. It is, however, sometimes possible to demonstrate the decrease in the powers of resistance of a whole group of persons placed under special conditions of environment, who then fall a prey to epidemic disease. Such was the case in the epidemic of scurvy, an account of which I published in 1893, due to troops being exposed to the vicissitudes of a particularly severe winter. The streptococci, which are normally present in the mouth, gave rise to the first morbid symptoms and paved the way for a fusiform bacillus which invaded the gums and caused hæmorrhage by irritative hyperplasia of the walls of the vessels.

It appeared advisable to recall these facts, although

the subject of the present contribution is of quite a different nature. It is no longer a question of two non-epidemic infections—one, at least, of which is common—which by their association acquire the epidemic character, but with cases where the primary affection or some unknown cause is complicated by one or several specific and epidemic infectious diseases; I shall describe such morbid combinations under the name of "associated epidemics." It is, for instance, not unusual for an epidemic of influenza or of pneumonia to complicate some pre-existing affection; in such case the second affection may, more or less, completely mask the clinical physiognomy of the original affection. This is especially so when influenza intervenes, to such a degree indeed that we question whether, in many epidemics of so-called influenza with a high mortality, infection by Pfeiffer's bacillus, usually comparatively inactive, ought not to be considered as a complication of an unknown primary affection. These questions were suggested by our bacteriological researches, by means of which we discovered micro-organisms possessing all the characters of Pfeiffer's bacillus in affections the influenzal nature whereof was doubtful, and which exist independently of any epidemic of influenza. This point of view appears to be confirmed by certain facts which we recently noted at Bucharest, which we will now describe.

For several years past influenza has regularly occurred at Bucharest during the cold and damp season, and the winter of 1900-1901 was no exception to this rule. Nevertheless, the epidemic remained of a mild type until, towards the end of the bad season, a certain number of cases of a serious nature occurred in two distinct districts. One of these districts had only lately been incorporated in the town (the Mincu quarter) and was intersected by large ditches full of stagnant water which had been dug in order to get at the clay and which are actually being filled up with all kinds of rubbish. In close proximity to these ditches live, under deplorable hygienic conditions, a shifting population whose only occupation consisted in searching for rags, bones, &c., in the rubbish heaps. The second quarter was another suburb, also inhabited by Tziganes who lived under similarly unhealthy conditions. Altogether there were about forty cases with several deaths in these two quarters.

The clinical picture presented by the patients was anything but similar. In nearly every case, however, we noted the presence of Pfeiffer's bacillus, but on the other hand, the primary infection—difficult enough to identify—may possibly have been different in each case.

Thus, in one of the first cases, typhoid fever might be suspected as the pathological substratum. The patient was a lad, æt. 15, living in the Mincu quarter, who had been ill ten days. He was admitted in a septic state, with a high continuous fever (40°C) and a generalised eruption of a red colour, hæmorrhagic

and spotted with brownish stains; he died in six days. Serodiagnosis gave a positive result at 1 in 50; moreover, very marked cerebral symptoms (cephalgia, opisthotonos) having been noted on the last day, we diagnosed typhoid fever with meningitic manifestations. The histological and bacteriological examination at the post-mortem proved the existence of a hæmorrhagic infection: gastric ecchymoses, hæmorrhagic pachymeningitis, hepatisation of the lungs, considerable subacute hypertrophy of the spleen, and commencing acute myelitis. Neither by the microscope nor by cultivation could we discover Eberth's bacillus. The bronchi, on the other hand, contained Pfeiffer's bacillus, well characterised from morphological and culture points of view; it did not give rise to any symptoms on inoculating a rabbit. In spite of the result of the bacteriological examination there does not seem to be sufficient ground to discard the hypothesis of aborted typhoid, especially as Peyer's patches were injected, though without cicatrix or tumefaction.

In one of our other patients we were rather inclined to consider measles as the primary affection. The patient, a boy, æt. 17, also an inhabitant of the Mincu quarter, had been suffering for six days when he was admitted to Felantropia Hospital, with the clinical aspect of a grave hæmorrhagic infection: continuous fever (from 39° to 40° C.), exhausted, delirious, and suffering from a morbilliform hæmorrhagic eruption over almost the whole of his body, but more marked on the thorax and the abdomen, not invading the face. In spite of the grave nature of the symptoms, recovery was perfect, and the patient left the hospital in three weeks. The sero-reaction was always negative; neither the blood nor the expectoration contained any pathogenic agent, and this fact confirms us in the opinion that we had to do with an infection possessing a non-cultivable microbe, such as that of measles. In any case it was complicated by an influenza infection, for repeated examinations of the purulent sputa enabled us to recognise Pfeiffer's bacillus, which disappeared after recovery.

We observed another case of a similar kind, which we think may be explained in the same manner. A young man, æt. 20, entered the hospital, at the end of the first week of illness, with high continuous fever (41°), prostrate, delirious, and suffering from a hæmorrhagic eruption, though less characteristic than that of the patient whose history we have related above. This also did not invade the face. Recovery was complete at the end of thirteen days. The sero-diagnosis always gave a negative result; bacteriological research only revealed the presence, in large numbers, of Pfeiffer's bacillus in the expectoration.

In the two last cases, therefore, influenza, and possibly measles, may be incriminated, while in the first, one is inclined to the view of an association of influenza and typhoid, just as in respect of the three patients whose histories are briefly given later. The latter entered the hospital at between the fourth and the seventh day of the disease, with high fever. They all gave marked sero-reaction, while their purulent sputa contained an abundance of Pfeiffer's bacillus—either free or in leucocytes—associated with other microbial species. Nevertheless, the nature of the primary infection underlying influenza remains doubtful; at first we were unable to isolate Eberth's bacillus; moreover, these patients came from a quarter ravaged by a very peculiar epidemic; lastly, in cases of a similar character where the sero-reaction gave a positive result, we were unable, at the post-mortem, either to demonstrate the lesions of typhoid fever or to discover the specific micro-

organism. Here are a few details concerning these three cases:—

A woman, æt. 30, was attacked, five days previous to her entry into hospital, by shivering and fever, accompanied by epistaxis, muscular and articular pains, and cephalalgia. There was slight dulness at the base of both lungs; on auscultation, a few sibilant disseminated râles were noticed; a slight cough, a scanty muco-purulent expectoration. The belly was slightly swollen; the spleen had not apparently increased in size; a moist tongue; loss of appetite; a temperature of 40.5° C. It was only on the third day that patches of a deep red colour were observed on the back, limbs, and abdomen, pretty evenly distributed, the size of a bean, and disappearing on pressure. At the end of a week her condition became worse; nocturnal delirium, a furred tongue, and a temperature of 39.2° C. The patient was in a state of collapse, and lay motionless on the back, the belly being tympanitic and the right iliac fossa tender. Two days later the temperature fell, her general condition improved, and the eruption began to fade. The patient was discharged quite well fifteen days after admission. Widal's sero-reaction gave doubtful results; a week later agglutination appeared almost instantaneously in the proportion of 1 in 20; five days before her discharge we again obtained well-marked and rapid agglutination. Cultivations inoculated with fæces by Piorkowski's method did not give any characteristic colonies. On the other hand, the bacteriological examination of the sputum revealed an abundance of Pfeiffer's bacillus, also diplococci and small chains of barley-like organisms, taking the Gram stain. Cultures on blood enabled us to isolate Pfeiffer's bacillus.

The affection was ushered in in an almost identical manner in a man, æt. 53: a sudden onset with violent and repeated rigors, epistaxis, nausea, high fever, myalgia and arthralgia, anorexia, constipation and delirium. The patient was admitted into hospital on the seventh day; he was restless and the pulse was frequent and feeble (138), temperature 39.3° C. Some sibilant disseminated râles were noted; the belly was swollen, the spleen was large; all the body, excepting the face and the neck, was covered by a macular eruption; these patches, which varied in size from a millet seed to a bean, did not project; they were of a dark red colour (a few were lighter), and disappeared on pressure. During the following night the patient was violently delirious, and his expectoration was streaked with blood. The eruption assumed a markedly petechial character, especially on the abdomen and back; the temperature was 39.8°. Five days later there was a slight improvement; the delirium ceased, and the temperature fell to 37.5°. The eruption commenced to fade, the deep red patches being replaced by greenish stains. The patient was discharged quite well a fortnight after admission. The sero-reaction, which yielded an uncertain result on the second day after admission, gave a positive result a few days later; marked agglutination, even in the proportion of 1 in 50. Cultures by Piorkowski's method gave no result. The examination of the sputum showed a large quantity of very fine bacilli, possessing the characters of Pfeiffer's bacillus. Cultures on agar and blood enabled us to cultivate and isolate this bacillus, which was not present in extra-vascular areas.

In the last of these three patients the clinical aspect was approximately the same; the eruption was, however, much less marked. The patient, a young man, æt. 18, had felt unwell since January; he became worse towards the end of March, and was received on April 4th. His temperature was 40.2°, and his pulse 120. He complained of pain in the back, muscular pain, headache and cough. The belly

was tender, especially in the iliac fossa, and slightly tympanitic; the spleen was apparently not enlarged. There were bronchial *râles* in both lungs; mucopurulent expectoration. Several non-prominent red spots were observed on the back. A day or two later the patient felt better, the temperature fell to normal, and he was discharged on April 18th, completely cured. Widal's sero-diagnosis, which was attempted on several occasions, gave a positive result; the agglutination, at first feeble, became afterwards very characteristic in a dilution of 1-50. The expectorations examined on April 7th contained an abundance of fine bacilli, presenting the characteristics of Pfeiffer's bacillus, and a number of other microbes (streptococci and bacilli having the appearance of pseudo-diphtheritic bacilli. Pfeiffer's bacillus was present.

So far, in all the cases we have related, we had only to deal with the association of two infections, one of a doubtful, not to say unknown, nature, the other of an influenzal nature. But in this epidemic there arose other clinical combinations of a much more complex nature, as is shown in the case of a young girl, *æt.* 15, admitted on the fourteenth day of the attack, suffering from an infectious fever displaying certain features of typhoid, giving Widal's sero-reaction in the proportion of 1 in 40; later on pneumonia supervened, as well as a septic condition, which became more and more marked, and which finally caused death. Even just before death the examination of the sputum failed to reveal Pfeiffer's bacillus, which were, however, found post-mortem, in the contents of the bronchi, associated with the staphylococcus, streptococcus, and pneumococcus. Some rabbits inoculated with the influenza microbe remained healthy. In addition there was a patch of pneumonia, recent pulmonary gangrene, softened, pulpy cavities, forming a kind of abscess, and a hæmorrhagic zone between the pneumonic area and the pulmonary tissue; microscopically, the pneumonia presented the characteristics of the fibrinous variety with large coloured cells, while in the gangrenous parts the extremely dilated alveoli had coalesced and were filled with leucocytes undergoing degeneration. The bacteriological examination revealed in the lungs the staphylococcus aureus, a streptococcus and the pneumococcus, which were also found in the microscopical sections; I also found in great quantities a fusiform microbe which we were able to cultivate. Among the other peculiarities, must be mentioned the softened and swollen state of the mediastinal glands, which contained a special proteus along with the pneumococcus. In the peritoneum we found the same microbe and also a streptococcus. We were able to isolate the staphylococcus aureus from the liver and the spleen. The small intestine was hyperæmic and swollen in certain limited areas, and on excising a loop of intestine between two ligatures we found that the tumefaction was the result of an abundant superficial desquamation and exudation, cellular and albuminous, entirely filling the lumen of that part of the intestine. This exudation, as well as the blood &c., contained a quantity of yellow pigment. Except for an insignificant swelling of Peyer's patches, there were none of the anatomopathological or bacteriological characteristics of typhoid fever. Thus there seems to have been a general infection by the pneumococcus, the streptococcus, the staphylococcus and Pfeiffer's bacillus, without our being able to distinguish the role of each of these micro-organisms.

Lastly, there may occur, in an individual predisposed by a pre-existent affection, a particular localisation of one of those microbes which occur in an associated epidemic, a microbe which afterwards becomes generalised. To illustrate this, I may relate

the case of a man, *æt.* 57, who came from the second epidemic district, and was admitted to the Colentina Hospital on the seventh day of the attack, along with several other patients with whom he had mixed, who were thought to have contracted typhus fever. This man displayed all symptoms of a grave infectious fever simulating exanthematous typhus, but without the eruption; profound depression with high fever (40°), cyanosis, an anxious facies, a rapid pulse (140), which was feeble and arrhythmic; a large spleen, the belly slightly prominent, but not tender. On auscultation we discovered widespread sibilant *râles*, and a few moist *râles* at both bases. Sero-reaction gave a negative result in the proportion of 1 in 40 and even 1 in 20. The patient died in three days. The post-mortem examination revealed arteriosclerosis of the heart and a slight degree of nephritis, also of an arteriosclerotic nature; but the most important lesions were widespread hæmorrhagic bronchitis. It also appears very probable that the infection was propagated through the air, producing the infectious symptoms as well as an aggravation of the condition of the heart and the kidneys; in other words, we had to do with a hæmorrhagic bronchial infection, caused, as it seemed, by Pfeiffer's bacillus, in a nearly pure culture, in the bronchi and lungs, but which, when inoculated into a rabbit, had no effect; side by side with this micro-organism we discovered, in a small quantity, a bacillus resembling that of glanders, non-pathogenic, however, for mice and guinea pigs.

The eight cases which we have just related belonged to an epidemic in two districts—unhealthy *par excellence*—which broke out among half-starved and ill-lodged rag-pickers, and which we should not have hesitated, at other times, to diagnose as exanthematous typhus; but our researches on these eight patients revealed the presence of Pfeiffer's bacillus, and in most of the patients we obtained, in addition thereto, Widal's sero-reaction, although we were unable to detect the slightest trace of typhoid lesions or to discover Eberth's bacillus.

We cannot explain these peculiarities on the assumption of an abortive typhoid fever, which had passed and disappeared unperceived, for very often the agglutinating reaction was absent at the onset, or at least was but feebly characterised, whilst, later on, it became very marked. Nor can we admit the hypothesis of a simple epidemic of abnormal influenza, since, in some cases, Pfeiffer's bacillus was absent during the first days of the affection but appeared later on; moreover, this micro-organism was met with in large quantities in the oldest areas of pneumonia, softening, and pulmonary gangrene. These various considerations lead us to infer that there must have been another hidden element, representing the primary infection the microbe whereof eluded recognition, and that this infection was complicated by Pfeiffer's bacillus, probably also that of Eberth, this latter, through some peculiar circumstances, not having sufficiently multiplied to bring about the lesions of typhoid fever and to invade the blood.

It may be that there was no specific primary infection—exanthematous typhus, &c.—but only a loss of resistance on the part of organisms enfeebled by defective hygienic conditions, a loss of resistance which allowed of the invasion of common microbes (streptococcus, &c.), which prepared the soil for specific germs, such as Eberth's or Pfeiffer's bacillus.

In any case our observations show that it is not sufficient in an epidemic to find Pfeiffer's bacillus in order to affirm that we are dealing with influenza, nor does a positive sero-reaction enable us to affirm that it is typhoid fever, for it is possible at the same

time to find both these elements of diagnosis in the evolution of a particular syndrome—associated epidemic, which is neither influenza nor typhoid. We may even question whether certain cases diagnosed as exanthematous typhus are not also due to associated epidemic diseases.

From an epidemiological point of view the facts that we have just related tend to show that every epidemic is not produced by a single specific microbe, but that, on the contrary—as we formerly established for individual affections—there exist particular associated epidemics, provoked either by ordinary causes or by the associated factors, or by specific germs complicating other equally specific infective states, as yet undetermined. No doubt now that attention has been drawn to this point, our knowledge of these facts will make rapid progress.

THE SUCCESSFUL TREATMENT OF TUBERCULOSIS AND LUPUS BY GARLIC.

By W. C. MINCHIN, M.D., T.C.D.,
Medical Officer of Kells and of the Fever Hospitals.

I WISH to record a new treatment for tuberculosis which I have adopted for the past three years and a-half with remarkable success. When I commenced this treatment I had some reasons for believing that the plant known as *allium sativum*, or garlic, exerted a specially destructive influence upon the tubercle bacillus, at all events when it attacked the human subject, I am now satisfied that no treatment has yet been brought forward which will give anything like such satisfactory results as the treatment by this substance.

I look upon it as a perfectly safe treatment and also an efficient one in all cases of incipient pulmonary tuberculosis, in nearly all cases of moderately advanced, and in many very advanced cases. Its action is fairly rapid, and the treatment by it is scarcely open to any objection, it being applicable to all cases of consumption either in the wealthy or the poorer classes, in their own homes or in the general wards of any hospital. I have had so much success with it that I have come to look upon few cases of consumption as hopeless. I enclose two cases which you might kindly publish as examples.

One M. C., an incipient case of bilateral pulmonary tuberculosis, sputum contains tubercle bacilli, dulness in both apices, with profuse night sweats, cough and expectoration, has had hæmoptysis, evening temperature 99.4° F. On the fifth day of treatment the temperature became subnormal, the cough and expectoration commenced to diminish, the night sweats commenced to stop. On the eleventh day the night sweats had entirely stopped. On the nineteenth day the cough and expectoration had become extremely slight. His recovery has gone on quite satisfactorily in every way. He was admitted on April 7th, 1902. His weight on April 10th was 11 st. 4 lbs., and on May 12th 12 st. 6 lbs.

The second was a very advanced case. Pulse, 110; respirations, 35; temperature, 100° when treatment began. Profuse night sweats ceased eleventh day of treatment. Temperature became normal middle of fourth week. Respirations became normal fifth week. Cough and expectoration almost gone at the beginning of the seventh week. This patient could not be weighed upon admission. He was sent into hospital as a far advanced and hopeless case. On arrival he appeared to be rapidly approaching the end. He had been for two months in bed and was unable to walk. He was as emaciated as he very well could be, with the usual distressing symptoms. Both lungs had tuberculous infiltration in every part with

a considerable amount of apical dulness on each side. Dyspnoea was very severe and the patient could scarcely speak. He also suffered from an ischio-rectal abscess. The heart's action was very feeble, and the sputum, which was extremely abundant, contained numerous tubercle bacilli. His improvement was marked from the beginning of the treatment. He is now strong and well.

I have treated in all about fifty cases of pulmonary tuberculosis, with results which justify the statements which I have made.

So many germicides and inhalations have been advanced with disappointing results, that I merely wish to state the fact that this has been strikingly successful in my hands, and that whilst inviting others to try it, I need scarcely state it is a harmless drug.

A short time ago I asked Dr. Wallace Beatty, of Dublin, to try it. He has very kindly been doing so, but he has not had sufficient time to speak as to its curative effects, but he has told me that in most cases in which he has tried it the relief of cough has been very remarkable, and that some of his patients have expressed themselves as feeling in every way better. His experience is too short to say more than "as far as the relief of the cough of phthisis is concerned it has succeeded better than any drug he has tried." I have no doubt that in twelve months he will endorse all that I say.

I have found this substance equally valuable in the surgical aspect of the disease, and I believe it will open up a new field of surgery. I have only tried it in those cases in which the tuberculous tissues were exposed, and consequently the remedy could be applied to them directly, such as tuberculous ulcers, open abscesses and glands, and cases of tuberculous osteitis and such like in which the skin was broken. In these cases there is invariably an improvement and generally a permanent healing. My experience of it in cases of lupus is, I regret to say, confined to one case, but it was so successful that it seems to point to a bright future for it in these cases. It is now seven weeks since I began to treat this case of extensive lupus of the nose, cheeks, and ears of fourteen years' standing. After the seven weeks' treatment with *allium sativum* it is almost well, and the lupoid area has assumed the appearance of healthy skin.

I have some reason to believe that even in the vicinity in which garlic is grown in large quantities the tubercle bacilli do not abound.

In all my cases I have used the freshly expressed juice of garlic without removing the chlorophyll, and, as I have experienced some difficulty in procuring it, I invariably express the juice myself.

In pulmonary cases I dilute this pure juice with an equal part of distilled water and apply it upon the sponge of a large perforated zinc respirator such as is recommended for antiseptic inhalations by Dr. Burney Yeo. It is applied freshly two or three times daily to the sponge with a small brush. The respirator is worn as continuously as possible for the first few weeks, after which time I advise its use for about three hours daily.

Where there is evidence of intestinal trouble I give the fresh juice by mouth in doses of 20 M diluted.

In laryngeal cases I have met with success by using a 1 in 20 solution with an ordinary throat spray, using it frequently.

In surgical cases and in the case of lupus which I have mentioned I employ the undiluted fresh juice.

Very unhealthy cavities should, of course, be first washed out with some antiseptic, when a little of the juice may be injected into a cavity, covering the outlet with a similar dressing on lint. In the lupus case I directed the fresh pure juice to be painted over the affected parts every night, and washed off in

the morning with oatmeal water. I have met with four different varieties of garlic which are cultivated; all of them appear to be possessed of similar properties with regard to their antagonism toward tuberculosis.

There is also a wild variety which I have not tried, and possibly the whole genus possesses the same properties.

Garlic is largely used by the country people throughout Ireland, and many of them grow it every year. It enjoys a reputation among them for curing coughs when it is used as an infusion and mixed with whisky. It is also used when pounded as a poultice for strumous sores; and, further, it is said to prevent symptomatic anthrax or "blackleg" in cattle, and is largely used for this purpose also.

Some preparations of garlic are official preparations of the United States Pharmacopœia, being recommended as an antiseptic, an expectorant, a rubefacient, a diuretic, an antispasmodic, and a carminative. It contains a volatile oil—sulphide of allyl—to which it possibly owes its properties.

In conclusion, I must thank Drs. Ringwood and Brangan, of Kells, for the generous manner in which they sent their tuberculous patients to me when they recognised the merits of the treatment.

THE SERUM TREATMENT OF PLAGUE. (a)

By H. C. DRURY, M.D., F.R.C.P.I.,

Physician to Sir P. Dun's Hospital.

It is evident that in plague, as in other zymotic diseases, the "type of disease" varies widely in different epidemics, and that consequently statistics will vary widely also. In the Report of Dr. N. H. Choksy, Special Assistant Health Officer, Bombay Municipality, on the Treatment of Plague with Professor Lustig's Serum, at the Arthur Road Hospital, Bombay, for the months February to May (inclusive) 1901; it appears that in 1900 the type of disease was one of gradually increasing severity, which reached its climax in the period under review. This severity was manifested by the following characteristics:—

1. *Multiple Buboes*.—In previous epidemics multiple buboes existed in a comparatively small proportion of cases, about 13.9 per cent., but in this epidemic the ratio was increased enormously, to 63 per cent.

2. *Septicæmia*.—In all the cases admitted the blood was examined at the time of admission. Cultures showed that 45 per cent. of cases were already septicæmic; and out of 165 such septicæmic cases there were only four recoveries. This in itself is sufficient to show their gravity.

3. *Prolonged Duration and Frequent Relapses of the Cases*.—Whereas, in former epidemics a patient was considered practically safe if he passed over the tenth day of illness, there was practically no time limit in this epidemic after which the patient could be considered to be out of danger.

4. *Late Suppuration of Indolent Buboes*.—Such buboes have been opened as late as the forty-eighth day of illness, and the pus has been found to contain active plague bacilli capable of growth. This opens up the question, whether a plague patient though free from all acute manifestations of the disease, may yet be liable to auto-infection or capable of infecting others after a long interval.

5. *Complications*.—These existed with greater frequency than in other epidemics, were graver in their import, and contributed greatly to the high rate of mortality.

6. *Greater Resistance to the Action of Serum*.—As the epidemic advanced in 1900 it was found necessary to increase the amount of serum administered, and so in 1901 this had still to be augmented, without, however, corresponding benefit to the cases. The serum treatment yielded on the whole results which were not at all so good as in the previous year. Indeed, a hasty glance at the figures might lead one to the impression that little or nothing had been attained by this treatment, but "an analysis of the cases at once reveals whether the serum has been useful or not, and to what extent." Dr. Choksy appears to have no doubt about its utility, and he goes to considerable pains to show why the results have been so disappointing.

The report opens with "A Brief Résumé of Recent Researches in Bacterio-Therapy," which is in itself most valuable. In this it is pointed out that the reason why serum treatment has not been so satisfactory in cholera, typhoid, and plague as in diphtheria and tetanus, is that the latter are *intoxication diseases* in which the bacteria remain *in situ* at the point of inoculation, the symptoms being almost exclusively due to the action of a toxin excreted by the microbe as a sort of metabolic product, whereas in the former, i.e., plague, &c., the specific poisons of the bacilli are not excreted by them but are retained in the protoplasm of the microbes. Hence curative properties can only be expected if the anti-bodies or immune bodies (in the sera) are capable of destroying the infecting bacteria, whether living or dead.

Prof. Wright, of Netley, submitted recently to the Pathological Society of London his observations on the "Bactericidal Action of Normal Blood." He found that the blood had no bactericidal power on plague bacilli. But that with typhoid and cholera bacilli the blood was very powerful, for instance, 1 c.c. of blood would kill about 10,000,000 cholera bacilli. These observations show what a difficult battle the system has to fight against plague infection. The résumé shows that the present position of serotherapy explains why the success of Lustig's serum has not been so encouraging as anticipated, and why also the results obtained during the epidemic of 1900-01 have not been so gratifying as during the previous year.

Septicæmia seems to have been a frequent and terrible complication, and to have rendered the serum treatment of plague itself practically useless. For instance, there were fifty-seven septicæmic cases treated with serum. Of these fifty-five died, two recovered—mortality, 96.662; whereas of seventy-six non-septicæmic cases also treated with serum forty-three died, thirty-three recovered—mortality 43.4 per cent., that is, 40 per cent. in favour of the non-septicæmic cases under the same treatment. Seeing, then, that the complication of septicæmia is so fatal, it seems a pity that trial was not made of the efficacy or otherwise of anti-streptococcus serum. If obtained from a trustworthy source and proved sterile, it could do no harm, and we have certainly seen cases where it appeared to have saved life. Our observations have, however, been so few and scattered that no trustworthy inferences can be drawn. Septicæmic plague cases would, however, seem to be very suitable for experiment as they occur in sufficient numbers, and in close consecutive series, so that observations could be uniform, and the data more trustworthy.

THE annual meeting of the Dublin Branch of the National Association for the Prevention of Tuberculosis will be held in the Royal College of Physicians of Ireland on Monday next, June 9th.

(a) A critical note on the Report of Dr. N. H. Choksy on the Serum Treatment of Plague at Bombay.

Clinical Records.

TWO CASES OF DISSEMINATED SCLEROSIS. (a)

Under the Care of JAMES CRAIG, M.D., F.R.C.P.,
Physician to the Meath Hospital, Dublin.

THREE years ago I exhibited a man suffering from disseminated sclerosis whose symptoms tallied in a most exact manner with the classical picture of the disease as described by Charcot. There were nystagmus, intention tremors, scanning speech, and spastic paraplegia. I also reported a case which showed that the disease might occur in early life, and finally I described the course of the disease in a female patient as illustrating one of the most important types of the so-called aberrant cases. The symptoms started with blurring of vision of an evanescent nature, followed by attacks of transient paresis of the limbs. Six years passed before nystagmus was observed, fourteen years before the spastic condition of the limbs became developed, sixteen years before intention tremors appeared and syllabic speech could not be said to have occurred at all.

On the present occasion I am enabled to exhibit two cases of the malady in order to further demonstrate the variety of types under which the disease may be met. The first patient is a blacksmith, *et.* 22, with good family history, who two years ago had a weakness in his legs which passed away in a couple of months. A year ago the weakness returned and has increased since. He had a feeling of pins and needles in his left arm and leg. Some delay preceded the act of micturition during the earlier months of illness. On asking him to walk it is seen that his gait is staggering, titubating, or cerebello-ataxic. He can stand with his heels together and his eyes closed, showing that he has not true ataxia. He has "slight vertical nystagmus, well marked nystagmic twitchings at extreme lateral and upward positions of the eyeballs, but none at inferior position. Vision, field of vision, and fundus of eye are normal." His inferior extremities are in the condition of spastic paraplegia: increased knee jerks, ankle clonus, and toe extension on stimulating the plantar reflex. His speech is of an explosive character; he has no intention tremor. The cerebellar gait, suggestive of tumour of the cerebellum, is not accompanied by headache, vomiting, or optic neuritis.

The second patient is a fisherman, *et.* 30, with good family history. He dates his first troubles nine months back, when his right leg became weak, then his right arm, and these were accompanied by a feeling of "pins and needles." He does not complain of his left extremities at all. When he walks he represents the spastic parietic gait in his right leg; he gives his right shoulder a heave up in order to clear the foot in advancing it, but the anterior part sweeps the ground. Mr. Swanzy kindly examined his eyes, as well as those of the first patient. He reports: "R. eye, slight internal strabismus (concomitant), which patient states he has always had. Nystagmus, slight lateral in R.E., and very occasional twitch in L.E. Nystagmic twitchings at extreme lateral positions of the eyeballs. Vision, R.E. $\frac{5}{6}$, L.E. $\frac{7}{8}$."

Field of vision: R.E., probably a central colour scotoma; L.E., no scotoma.

Ophthalmoscope: R.E., outer third of optic disc very pale; L.E., entire optic disc of a pale buff colour."

The intention tremor is well marked in his right extremities, scarcely at all in the left. His speech is not properly speaking syllabic. His lower limbs show exaggerated knee-jerks, extension toe phenomenon and ankle clonus in the right side. His right wrist-jerk is increased. Sensory disturbances are absent. His bladder and rectum are not affected. The disease in this man represents a distinctly hemiplegic type, and bears a striking contrast to the other case.

The ocular phenomena in this malady are of the utmost importance. A transient amblyopia with or without change in the optic disc may be the very earliest manifestation of the disease. Pallor of the disc in one or both sides, or affecting only the outer part of the disc

is of much diagnostic importance, and this pallor may exist for a time without any defect of vision. The sixth nerve is the most frequently affected when one of the oculo-motor nerves is engaged. Peripheral limitation of the field of vision is generally a late manifestation, and is accompanied by appearances of optic atrophy.

TETANUS NEONATORUM.

By J. C. McWALTER, L.R.C.S.I.

DUBLIN at one time enjoyed an unenviable notoriety in the matter of tetanus neonatorum, and the writer in Ziemssen's Cyclopaedia states that towards the end of the eighteenth century, almost 1,600 deaths out of 8,000 were attributed to that cause, now it seldom figures as a cause of death, doubtless due to the greater care with which our midwives are trained, but even those of them who have been trained in the best hospitals are inclined to get a little lax in asepsis, and most of all are inclined to regard the sterilisation of the scissors as a matter of little moment, concerned as it is with the cutting of structure which must normally decay. An infant was brought to me on May 12th, the mother stating that the child obstinately refused the breast, and was very restless and sleepless. It was a healthy, well-nourished child of nine days old, the youngest of a family of twelve, of whom nine were living. Up to the seventh day it had thrived satisfactorily, but had now become intensely irritable, annoyed at the slightest sound or touch, and could not open its mouth. On introducing my finger I found the jaws rigidly locked, so much so that it would have been easier to fracture the jaws than to open them. There was intense rigidity of the spine, and tetanic spasm of the muscles of the limbs. The cord had not fallen off, but exhibited a blueish-red erysipelatous blush, with a zone of inflammation round its cicatrix.

Chloral and bromide of potassium with paregoric were tried internally, and starch enemata with three drops of laudanum were ordered, but they failed even to produce sleep, and the infant died in thirty-two hours.

The only excuse for recording such a case is to point out that the tetanus was evidently due to the midwife having used dirty scissors, and that asepsis in this respect is not merely a theoretical desideratum.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND. MEDICAL SECTION.

MEETING HELD ON FRIDAY, MAY 16TH, 1902, AT THE
ROYAL COLLEGE OF PHYSICIANS.

SIR CHRISTOPHER NIXON, M.D., President, in the Chair.

LIVING EXHIBITS.

DR. W. J. THOMPSON exhibited a case of ascending paralysis. The patient was a drayman for the last two years, and came into hospital on account of weakness of his legs; he had no loss of sensation and the reaction to the faradic current was normal. Eleven days afterwards, he was paralysed from his feet up to the superior border of the thorax. He could swallow fluids but not solids. He remained in this condition for weeks and then slowly recovered. At present he is able to attend to his duties, and his patellar reflex has returned.

DR. CRAIG read notes of "Two Cases of Disseminated Sclerosis," which will be found in preceding column.

DR. PARSONS read a paper on

ASCENDING PARALYSIS.

He said the patient was suffering from what is known as "Landry's disease," one of those in which the spinal cord showed no lesion; which though called Landry's paralysis, was he thought, really first recognised by a Dublin physician, Dr. Graves, who pointed out that in cases in which the spinal cord gave no evidences of any pathological lesion the mischief would probably be found in the peripheral nerve endings—a peripheral neuritis. The patient, who is the subject of the paper, entered the hospital complaining of numbness of his arms and legs. He quickly became worse, and in a

(a) Brought before the Section of Medicine, Royal Academy of Medicine in Ireland, May 16th, 1902.

week's time lost all power of his legs and was unable to get out of bed. He had been in the habit of drinking from four to six pints of porter daily. His cranial nerves were intact, he had no drop wrist, his temperature was subnormal, his muscle sense normal, but his hands were cold and clammy. The thoracic movements were normal, as were those of the diaphragm and abdominal muscles. He could not sit up in bed. He had no pain in his spinal column; his sensation was normal, as were his muscular reflexes; but his muscles were flabby, and he had lost the power of moving the legs. About one month after admission (October 14th), the right reflex was normal, and the following day the leg could be slightly flexed. On October 26th, he complained of great pain and tenderness in the calf of the left leg. On December 8th, he had so much improved that he could walk a little by himself, and last month he called to inquire if he might go on a roof to work. The treatment consisted in massage, the use of stimulating liniments, and the internal use of strychnine. Dr. Parsons quoted Gower's views as to the site of the lesion, and concluded that the paralysis was dependent on a toxic agent which had an affinity for the motor cells.

Dr. O'CARROL then brought forward two cases of "ascending paralysis." He said his first case was that of a lunatic asylum attendant who entered hospital with pain over the region of the stomach. He was an alcoholic; his lower eyelids were puffed, he was syphilitic, his urine was full of casts, and about thirty ounces in amount in the twenty-four hours; his temperature ranged from normal in the morning to 101° in the evening of each day. After having been for three weeks in bed, it was noticed that the patient's legs were feeble. On October 31st, he was found to be slightly paralysed, and the reflexes were lost. On November 2nd, he had weakness of his hands and arms; his mind was clear. On making an autopsy the dura mater was found much thickened, as was the frontal bone; his brain was normal. On opening the spinal canal *arachnitis ossificans* was found. All these lesions were looked on as the products of the syphilis; but nothing was seen that could be considered as the cause of the paralysis. The second case was that of a lithographic artist, who gave the history of a severe wetting and a cold, the result of a flooding of the lower storey of the dwelling-house. Forty-eight hours after he took to bed, where he was examined on December 3rd. He lay on his back, unconscious of danger, with his limbs extended. The reflexes were absent, and the urine was dribbling from his bladder, and he had had no motion from his bowels since he took to bed. He winced when the hairs of his legs were plucked out, and he is unduly wakeful. On December 6th, he was much worse, and was found to be paralysed both in his limbs and trunk. His mind was quite clear. He died on the 9th, of paralysis of the diaphragm. No autopsy was to be obtained. In this case we find the paralysis to have been preceded by a short pyrexial attack. The first case may be looked on as one of multiple peripheral neuritis; it is, however, difficult to include the second in this class, the bladder trouble being probably caused by some intra-spinal lesion. The name Landry's paralysis conveys little, for we find that of the ninety-three cases reported, which Bury analysed, but three came within the category of the strict definition. It may be looked upon as a useful clinical name for a group of well-marked symptoms but of no pathological significance.

Dr. FINNY said he had a feeling of doubt as to the meaning of Landry's paralysis after hearing the papers. Some of the classifications were confusing. In Landry's disease, the urinary organs are unaffected and the sensation is normal. Yet in two of the cases reported they heard that the patients had urinary troubles. The toxin seems capable of affecting the motor neurons and passing over the urinary centres in the cord. The absence of lesions may be accounted for by the insufficient means at the command of the pathologists in the past to detect them; and now when they are so much better prepared to detect lesions it is to be expected that they will be found. He had had two cases of the

disease under his care—one, that of a girl, *æt.* 18, who came to hospital after tramping about all night in rain. She complained of loss of motor power, paralysis supervened, quickly ascended to the respiratory centres, and she died of paralysis of respiration. He thinks there are many cases confounded with Landry's paralysis. He looked on Dr. Parsons's case as a typical example of the disease, and he also thought one of Dr. O'Carrol's was to be so considered.

Dr. DAWSON said he would like to know from Dr. O'Carrol if his first patient came from the Richmond Lunatic Asylum, for some of the earlier symptoms were not unlike the early symptoms of beriberi as noticed in that institution. If the symptoms were due to a toxin, it is difficult to understand how they should follow such a systematic course. He inclined to the view that the disease was the outcome of overwork and malnutrition, conditions that were fulfilled in Dr. Finny's case.

Dr. TRAVERS SMITH said that at the present time he had a case of Landry's paralysis under his care; the patient is a boy, *æt.* 11. On May 10th, the lad noticed that his knees were feeble, but if the knees were kept stiff he walked. On the 16th, the paralysis was marked, and if he attempted to cough, the abdominal muscles failing to act, the effort ended in a simple blowing sound. His voice production and sensation are normal; his reflexes are lost, and the deep muscle sense was not well marked. On examining the erector-spinae muscles it was observed that their reflex was increased. The boy is very hysterical, crying all day. He suffers from incontinence of urine. He (Dr. Smith) looks upon the disease as being due to a toxin, with a strong affinity for the motor neurons, to an action to which the visceral centres are not susceptible.

Dr. PORTER said he would like to know if Dr. O'Carrol's patient, who was an old soldier, had ever had malaria, or lived in a malarial country?

Dr. CRAIG said the name "Landry's paralysis" made a clinical picture. Toxins are prone to attack neurons, and he would add that the further from the central nerve-cell elements the axon is the more it is susceptible to the poison.

Sir CHRISTOPHER NIXON said he quite agreed with Drs. Craig and Travers Smith that the name "Landry's paralysis" is simply a clinical term, as is locomotor ataxy. He, in Landry's paralysis, recognised three distinct lesions—(1) Acute multiple peripheral neuritis; (2) acute anterior corneal myelitis; (3) acute ascending paralysis, with anterior myelitis. Dr. Parsons had given the credit to Dr. Graves, of Dublin, for first pointing out that when the lesion is not found in the central nervous system it may be found in the peripheral extremities. This he (Sir Christopher Nixon) thought did not fairly explain Dr. Graves's views. Dr. Graves placed on record his case, one of a patient, a sailor named McNab, who was suffering from a tight and painful stricture, and it was noticed that as the stricture was dilated so did his lumbar paraplegia disappear, and the ratio of improvement continued *pari passu*, so that when the stricture was fully dilated the lumbar paraplegia had disappeared, and the sailor was dismissed from hospital cured. M. Brown-Séquard, reasoning from the case, concluded that the peripheral irritation of the stricture had produced a reflex action in the nerve centre. Afterwards the same view was adopted by Hammond, the American neurologist, and others. Gull's views were much the same as those expressed by Dr. Craig, that the further the axon is removed from the trophic nerve centres, the more susceptible it is, such cases being in reality multiplex peripheral neuritis. That toxins do exhibit a preference for motor centres is seen daily in the action of curare, strychnine, quinine, ergot, tobacco, alcohol, and so forth. What the precise pathological lesion is, is unknown, and the cases have not helped to solve the difficulty.

Dr. PARSONS said he was not acquainted with Graves's writings; he was under the impression that it was during Graves's sojourn in Paris he made the observation that the lesion not having been found in the cord by the French pathologists, it may be situated in the peripheral extremities. Gower had expressed similar

views to those put forward by the President. Dr. Finny's case was recorded by Ross and Bury. There is a difficulty in defining Landry's paralysis. Of his two cases he gives one only in detail. On admission his patient had no loss of control of the bladder. The toxic agent affected the motor centres and very slightly the sensory ones. The pain in the calf of one of his legs, of which the patient complained when he commenced to get better, was due to thrombosis of some of the veins of the part, which were large and swollen.

Dr. W. J. THOMPSON said that the points of interest in the case he exhibited were (1) the age of the patient; (2) the fact that he had been exposed to cold; (3) the enlargement and subsequent diminution of the splenic area; (4) the complete control of the rectum and not of the bladder; (5) the slight exaggeration of the patellar reflex.

Dr. O'CARROLL said he thanked them for the reception his paper got and for the many useful hints he had received. The patient had been in India. He did not come from the Richmond Lunatic Asylum. He called his cases Landry's paralysis on account of the convenience of a term which had become widened to include diseases of that type. Is the lesion intra-spinal? We cannot say. The name is a convenient clinical one, nothing more, and they all know that asking questions is much easier than answering them.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

SUMMER CLINICAL MEETING

Held in the Royal Hospital for Sick Children, on
MAY 21ST.

Dr. T. R. FRASER, F.R.S., President, in the Chair.

Dr. BURN MURDOCH showed (1) a typical case of "microcephalic idiocy"; (2) a case of "bronchiectasis" in a boy. There was extremely well-marked clubbing of the fingers and toes, together with the signs of a vomica at the left base, and probably on the right side also. The patient brought up enormous quantities of very foul smelling oily yellowish sputum, which contained no tubercle bacilli. It was probable that notwithstanding the physical signs the condition really consisted in a multiple dilatation of numerous small bronchi, and water-colour drawings of the lung of a similar case were handed round to illustrate what was believed to be the state of matters in the patient shown. (3) A case of double infantile paralysis; and (4) numerous casts, photographs, and pathological specimens.

Mr. H. J. STILES showed, on behalf of Dr. Burn Murdoch, (1) a case of "basal meningitis" treated by tapping the ventricle. In such cases he thought that it was advisable to aspirate early, during the acute stage, and frequently every two or three days. He tapped through the parietal bone, first on one side and then on the other, and in young infants it was easy to push the needle through without preliminary drilling. In older children he used an archimedean drill, making a hole about one inch from the middle line just in front of the motor areas. Chloroform was not as a rule required, as the patients were apathetic and somnolent. He thought that as some cases recover without treatment, one was justified in supposing that in others tapping might just suffice to turn the scale. In this case the diplococcus of Weichselbaum was present. (2) A case of "congenital hydrocephalus."

Mr. STILES also showed (1) a case of "microcephaly" after operation by Dumont's method of linear craniectomy. (2) "Extensive nevus" (cutaneous and subcutaneous) of the face, which had been treated by electrolysis with very partial success. He thought that these large nevi were best treated by multiple puncture with the actual cautery, using the small point of Paquelin. As a rule there was no sloughing, and the burns healed in about fourteen days. (3) "Diffuse tuberculous osteomyelitis" of both tibiae. (4) A case of "canorom" oris after operation by free removal of the disease, and swabbing with strong solution (Merck's) of peroxide of hydrogen. Considering the destruction

of tissue there was surprisingly little deformity now that cicatrization was complete, and he did not think that further improvement would follow a plastic operation. (6) Cases of "excision of joints." It used to be said that excision of joints was a bad operation in young children on account of the subsequent interference with the growth of the limb. With this view he did not agree; indeed, he looked upon amputation as excessively rarely necessary in children. As a rule no shortening followed excision; in fact, he had a case of removal of the knee-joint in which there was actually about a quarter of an inch of lengthening, and he thought that the operation sometimes stimulated the growth of the parts. In the case of the knee he used Kocher's J-shaped incision, leaving the patella and not interfering with the quadriceps extensor; the surface of the tibia was left concave, and that of the femur convex. A rigid joint was aimed at as giving the best result. The cases shown had been operated on in 1898-99. No drain was ever inserted, and the subsequent treatment consisted in fixing the limb vertically in a Hamilton's splint with an upright side bar. The advantages of the position was cleanliness, complete absence of oedema, and the fact that the raw surfaces of bone were kept apposed by the weight of the tibia and firm union thereby favoured. For excision of the ankle he favoured a semi-lunar incision below the external malleolus, the peroneal tendons being divided and subsequently sutured. The malleoli were retained as far as compatible with complete removal of the disease. Of all excisions those of the knee and ankle gave the best results, possibly because in those joints rigidity, not mobility, was aimed at.

Dr. JOHN THOMSON and Mr. STILES showed a case of congenital "hypertrophy of the pylorus" which had been operated on about a fortnight previously. The baby had never vomited after the operation, and was now beginning to gain weight.

Dr. MELVILLE DUNLOP showed (1) a case of "hemi-hypertrophy of the right arm," leg and trunk. (2) A case of "persistent purpura" in a girl, *æt.* 9, in whom the disease began in the second year. On the slightest additional exercise, or blow, large hæmorrhages developed on the skin and subcutaneous tissue; latterly there had been epistaxis and bleeding from the mouth, but notwithstanding that these were most copious, little or no *anæmia* resulted. Otherwise the child was quite well. There had been no bleeding from the lungs, bowels, or kidneys; the blood was normal as regards its coagulability and microscopical characters. (3) A "cretin," *æt.* 9, who had been under treatment with thyroid for eight years. At present he had had none for about six months, and presented the ordinary appearance of a mild case, his stature being about that of a child of three. In infancy he had shown the usual sign, but the parents had not persisted in the treatment, hence the partial result. (4) Two cases of "pseudo-hypertrophic paralysis." (5) Cases of "abdominal tuberculosis" treated without operation. (6) A case of "pseudo-leukemic *anæmia*," whose blood showed marked poikilocytosis, abundance of nucleated reds, and moderate leucocytes, the lymphocytes preponderating over the polymorpho-nuclears.

Dr. JOHN THOMSON showed (1) a boy, *æt.* 3, with marked hysterical symptoms. The child had first suffered from so-called salaam movements when he sat up, while if placed on the back he rotated his head regularly and rhythmically from side to side. These movements were kept up constantly for long periods. Since admission to hospital cataplexy had been added, and a marked condition of *flexibilitas cerea* was now present. (2) Six cases of "Mongol idiocy" showing the characteristic facies, deformity of the hands, &c. (3) Two cases of "congenital rickets" occurring in a brother and sister, a third member of the family being similarly affected. When the patients were born they had very marked *cranio-tabes*, and evidence of intrauterine fracture with bending of the long bones. They were now dwarfed, the boy being 11½ ins. and the girl 5½ ins. below the average. The condition had probably nothing to do with rickets, though it was called intrauterine or congenital rickets.

In both cases there was a curious peculiarity of the hands which he had never seen elsewhere, namely, the fingers could not be completely extended. Both patients were perfectly intelligent. (4) A case of "achondroplasia" in a boy, *æt.* 14½, who was no taller than a child of seven.

Dr. J. C. DUNLOP showed (1) an early case of "microcephaly" in a child only a few weeks old. The fontanelle had been closed at birth, and none of the sutures could be felt. The case was extremely characteristic. (2) A case of "congenital heart disease" in which, in spite of a very loud murmur, the health seemed in no way affected. (3) A "Mongolian imbecile," presenting all the usual symptoms.

Dr. J. S. FOWLER showed (1) a case of so-called "congenital rickets." The patient was a boy, *æt.* 3, who was born with very extreme cranio-tabes, the occiput being practically unossified. On the third day he sustained a transverse fracture of the right femur, with no history of violence. This fracture united readily, with the formation of a large mass of callus. At the third month the left humerus was fractured, and at the eighteenth month the left femur, while the left humerus was again broken at the twenty-first, twenty-fourth, thirtieth, and probably thirty-third months. No signs of rickets had developed, but the growth of the child was considerably retarded. The condition differed somewhat from that of Dr. Thomson's case, in that there was no curving of the bones except as the result of the fractures, and there was no epiphyseal enlargement. Probably the condition was due to some defect of the periosteal ossification, and seemed more allied to *fragilitas ossium* than to true rickets. The fracture was all complete, never green-stick, as in rickets. (2) A case of "total right-sided hemihypertrophy" in a child, *æt.* 3, involving face and head, thorax, and arm and leg. There were, as in the previous case, numerous telangiectases. (3) A child, *æt.* 14 months, showing the results of simple "basal meningitis," which had begun about six months ago with the usual symptoms of fever, head retraction, loss of vision, increased knee-jerks, and more or less unconsciousness. When first seen about two months later there was a bulging fontanelle, head retraction, and blindness. As time went on the vision was recovered, the patient became less apathetic, but was evidently imbecile, and finally the bulging of the fontanelle disappeared. At this time the head began to enlarge, and did so at the rate of ½ in. per month until at present it measured 19½ ins. instead of about 18 ins.—that is, it was about the size of that of a child of three. As there was therefore evidence of the super-vention of hydrocephalus, and as lumbar puncture had been tried without success, some operation was contemplated. (4) A case of "rheumatoid arthritis" in a girl, *æt.* 13; the malady was of some six years' duration, and was of the type in which there is a great deal of synovial swelling without much bony outgrowth, and in which there is general glandular and splenic enlargement.

Dr. J. W. SIMPSON showed a series of cases illustrating the early diagnosis of rickets.

HARVEIAN SOCIETY OF LONDON.

CLINICAL EVENING HELD ON THURSDAY, MAY 22ND.

Mr. WATSON CHEYNE, F.R.C.S., President, in the Chair.

PARAFFIN AS A COSMETIC.

THE PRESIDENT showed a boy, the subject of congenital syphilis, who had suffered from necrosis of his nasal bones, and the bridge of whose nose Mr. Cheyne reproduced by the injection of paraffin, having a melting point of 110° F. at the first injection and 104° for the second, after a week's interval. After the two injections, the point of the nose, which had been held down during the operation, remained depressed, and a presentable organ resulted. The operation was difficult on account of the rapid freezing of the paraffin immediately it touched the tissues. One objection to the paraffin at 104° was that it had a tendency to run into the space between the eyes, above the bridge of the nose.

No inflammatory reaction had followed the injection. Greater improvement was possible, but the skin was at present stretched to its limit. He used an ordinary serum syringe. The great point was to have the hot water quite close to the patient's face, so that there was no time for the paraffin to cool. No pain was complained of during the injection.

Dr. A. MORISON showed a boy, *æt.* 11, the subject of
EARLY MITRAL CONSTRICTION, SHOWING THE TRIPLE RHYTHM.

The boy had acute rheumatism two years ago, and had had two attacks of chorea. He showed the usual phenomena of an ordinary mitral case. He did not think the triple rhythm could be regarded as diagnostic of the condition. The triple rub could be originated in pericarditic conditions, and under those circumstances the second sound might be spurious. Dr. Morison gave a review of the various theories held, namely by Sansom, Stacey Wilson, and others, and stated that in his view the triple rhythm was very much a matter of rate. If a patient with mitral disease and a triple rhythm was sat up in bed, and the pulse rate thereby quickened, the triple character of the beat vanished. When the patient lay down, and the pulse rate slowed, there was a quadruplication of sounds. He had verified that by sphygmographic tracings. In mitral cases one could sometimes, by the help of digitalis, produce quadruplication simply by slowing the heart.

Dr. SUTHERLAND thought Dr. Morison's theory plausible, but it required carefully thinking out. He would have thought the irregularity would have been more pronounced when the pulse rate was increased than when it was slowed. He could only recall one case, that of a woman, *æt.* 60, in which there was quadruplication of the heart sounds, and in that case he thought the innervation of the heart was at fault. An important diagnostic point, in his view, was the duplication of the second sound. If Dr. Morison had a case of slightly accentuated first sound and definite reduplication of the second sound, would he be prepared to diagnose mitral stenosis from those signs alone? His own view was that if those two signs were present, the case was very likely one of mitral stenosis. In his experience also, especially in children, the typical dilatation of the mitral orifice was more likely to be accompanied by irregularity of the heart's action than stenosis.

Mr. JAFFREY read notes of a case of

TORSION OF THE TESTICLE.

and showed the specimen. The text-books mentioned that torsion of the testicle most frequently occurred in undescended testes, but in the present case the testicle was completely descended. The patient, an errand boy, *æt.* 15, came to the hospital with an ordinary hydrocele of the tunica vaginalis. The swelling was of the size of a hen's egg. When riding a bicycle he fell over the handle and struck his hydrocele, which caused him much pain. A week later he again fell off his bicycle and struck the same part, causing him extreme pain, which brought him to the hospital. Hæmatocele was diagnosed. On operating, Mr. Jaffrey found no hæmatocele, the swelling being more or less due to oedema of the scrotum. The testicle was enlarged, very hard and black. On careful examination it was found that the testicle, instead of being attached to the posterior wall of the tunica vaginalis, had a mesentery of its own attached at the lower end of the epididymis. It was twisted three half-turns inwards. As it was a useless testicle, he removed it.

Dr. CAUTLEY showed a specimen of

CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS.

He said the disease was rare, and was but seldom diagnosed during life. Dr. Cautley had seen two cases when he read his paper before the Medico-Chirurgical Society three years ago, and collected eighteen others. Since then about fifty cases had been recorded. The infant was two months old, the age at which such subjects usually died, and the stomach was decidedly large for that age. The pylorus, instead of being a thin ring, was three-quarters of an inch long, and consisted of dense muscular tissue. Before it was laid open it formed

a very definite tumour, in shape like the last joint of the little finger. From the stomach side it was funnel-shaped, the funnel being closed largely by a fold of mucous membrane. After death the constriction was so pronounced that only a fine probe could be passed, and no fluid could be squeezed from the stomach through the orifice. The child was apparently born healthy, at full term, and seemed normal. After a period varying from a few days to weeks it started vomiting, but it was a regurgitant vomit; two or three meals would perhaps be kept down, and then a very large quantity would be brought back. The appetite seemed unaffected. The tongue was clean, and might remain so throughout the whole illness. The breath was not sour. Constipation was often, but not invariably, present, and was often noticed at birth. Occasionally there was diarrhoea. No bile was found in vomit. Towards the last such infants got very marasmic, and died practically from starvation.

Dr. Sutherland, Dr. Morison and the President took part in the discussion.

Dr. CAUTLEY replied.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, MAY 16TH, 1902.

Dr. W. A. WILLS in the Chair.

Dr. JAMES TAYLOR showed two cases: (1) a case of "paroxysmal hæmoglobinuria" in a child who had suffered from syphilitic ulceration in her palate; (2) a case of "Raynaud's disease" in a boy who had lost the terminal phalanges of several fingers, oxalates were present in abundance in the urine.

Mr. HERBERT CARRER-SMITH showed a case of "sporadic cretinism" that had been under treatment for four years with thyroid extract. The mental and physical condition had greatly improved, but relapsed as soon as treatment was omitted.—Dr. G. A. SHUTTLEWORTH thought that more improvement would be got if the treatment was persevered with. He believed it was never too late to try thyroid treatment.—Dr. EDMUND CAUTLEY asked whether the thyroid gland altered when treatment was stopped?—The CHAIRMAN commented upon the large doses of thyroid that could be taken by such children.—Mr. CARRER-SMITH, in reply, said the thyroid gland had manifested no obvious changes, at all events since the case had been under his immediate observation during the last three years.

Mr. A. BRUCE ROXBURGH showed a child with a fatty growth occupying the left side of the perinæum and scrotum. The testicle lay in the perinæum, and a hydrocele of the tunica vaginalis was present. The enlargement was noticed a few months after birth. He also exhibited a girl, æt. 5, presenting varicosity of the veins of the left lower extremity, with an extensive nævus of cavernous type on the outer side of the knee. A radiogram showed slight alterations in the length and shape of the corresponding tibia.—Dr. PARKES WEBER remarked that the presence of tumour formation in this case gave one the explanation of the resemblance between nævoid tumour formation and varicose veins.—Mr. R. CLEMENT LUCAS advised that the tumour, and, if necessary, a large amount of the cellular tissue should be excised.

Dr. J. PORTER PARKINSON showed two instances in the same family of a curious congenital depression of the frontal and parietal bones on one side of the cranium. The children, aged respectively two years three months and eleven months, seemed to be intelligent, and had never suffered from fits. There were no other evidences of maldevelopment.—Mr. E. W. CLAPHAM alluded to a similar case shown by him before the Clinical Society last year.

Mr. DOUGLAS DREW showed several cases illustrating the treatment of secondary conditions arising after operations for tuberculous joints.

Mr. SYDNEY STEPHENSON showed a case of "kerato-

malacia" in an emaciated infant of 7 months, suffering from tuberculosis, probably of the disseminated variety. The disease had already led to complete destruction of one eye. In the remaining eye the corneal ulceration had healed with the production of a nebula.—Dr. EDMUND CAUTLEY remarked that the temperature chart was not like that of tuberculosis. He asked whether the gonococcus could be excluded as factors in the case?—Mr. STEPHENSON, in reply, said there had been no ophthalmia neonatorum. The symptoms did not begin until the third month, and were those of keratitis and not of conjunctivitis. The latter, indeed, had been absent throughout the case. Clinically, at all events, the gonococcus could therefore be put aside.

Mr. WALTER EDMUNDS exhibited a girl, æt. 11, suffering from "subluxation of her left shoulder-joint." This he regarded as one of the after-effects of epiphytosis, with which she was affected as a baby. The arm could be freely moved in any direction except upwards.—Mr. R. CLEMENT LUCAS alluded to a somewhat similar case that had been under his care.—Mr. E. W. CLAPHAM mentioned another case of the same kind seen in a healthy man examined for life assurance.

Mr. H. BERTHAM ROBINSON showed an example of "Springel's deformity of one shoulder" in a girl, æt. 11. It had been noticed for two months only.—Dr. TRAVERS SMITH alluded to a case shown last year by him at the Polyclinic. Springel's theory was that in utero the arm got behind the back, and the shoulder was raised, thus bringing about the deformity.—Dr. HAWTHORNE asked whether a bony process in this case passed from the spinal column to the upper part of the scapula.—Mr. ROBINSON, in reply, said that no such osseous process existed in his patient.

Dr. JAMES H. SEQUEIRA exhibited a large sarcomatous tumour of the left suprarenal body from a girl, æt. 11, who exhibited the phenomena of "precocious puberty." The patient had menstruated for fifteen months, the mammae were very large, and there was a large growth of hair on the pubes, chin and lip. Secondary deposits were present in the lungs and liver.—Mr. R. CLEMENT LUCAS, Dr. Parkes Weber, Mr. H. B. Robinson, Dr. George Carpenter, and the Chairman discussed the specimen.

Dr. J. PORTER PARKINSON showed an organised intracardiac thrombus obtained from a boy, æt. 8.

Mr. DOUGLAS DREW exhibited a specimen and sections of an adeno-myxosarcoma of the testis taken from an infant.

Dr. C. O. HAWTHORNE read a note on a case of "arthritis accompanying ophthalmia neonatorum." After referring to the original observation of the association of the two conditions, made by Mr. R. CLEMENT LUCAS in 1885, and to subsequent experiences in confirmation of this, a case was described in which a purulent ophthalmia in an infant was accompanied by effusion into several joints, and by some periarticular swelling. The local conditions were unattended by evidences of acute inflammation, and in the course of a few weeks the affected joints regained their normal features.—Mr. R. CLEMENT LUCAS said it was pleasant to know that a clinical observation, made almost in the pre-bacteriological days, had been so amply confirmed. His first case was so acute that it appeared as if the joint must suppurate, but it did not as a matter of fact. He had almost met with the acute form as described by Dr. Hawthorne. The peculiarities of the affection were the tendency to recovery without suppuration and the association of suppuration in the conjunctiva.—Mr. SYDNEY STEPHENSON remarked that it was a pity gonococci had not been demonstrated in the eye discharges from Dr. Hawthorne's patient, but the other circumstances of the case rendered the existence of gonorrhoea quite conclusive. He had personally seen five instances of what might be termed "Lucas's joint disease," and of these, four made a perfect recovery under simple treatment. In the fifth case the joint was aspirated, and ultimately became ankylosed.—Dr. HAWTHORNE, in reply, admitted that the discharge from the eye should have been examined for gonococci. But there could be no reasonable doubt as to the diagnosis.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, June 1st, 1902.

WHITE SWELLING OF THE KNEE.

M. Lucas read a paper before the Académie de Médecine on the treatment of white swelling of the knee-joint. He said that the prevailing treatment of the present day for tuberculous disease of the articulations was prolonged immobility. That method gave only deplorable results, and in almost all cases resection of the knee should be substituted for such treatment. He practised that operation 113 times, on subjects varying from 15 to 40 years of age, without having once a fatal termination. The operation consequently might be considered as the best in the interest of the patient each time that the affection could be regarded as possible to be cured by ankylosis. There was, however, one condition to be borne in mind, and that was the total extirpation of the diseased parts, otherwise fistulæ would result. As to the shortening of the limb produced by the resection, far from being a misfortune it constituted a happy condition for the patient, as it was much easier for him to walk with a shortened straight leg than with an ankylosed limb which had its length preserved.

M. Delorme said that resection of the knee was without doubt an excellent operation in the treatment of white swelling, but like all other operations, it had its indications and counter-indications. When the lesions were very limited and circumscribed, it seemed to him that resection was too radical treatment, at least at the outset; an opportunity should be given to other means, medical or curettage, for instance.

ATTRITION OF THE FEMORAL ARTERY.

M. Legars communicated a case of attrition of the femoral artery, at the meeting of the Société de Chirurgie. A man, æt. 34, tramway conductor, was brought to the hospital suffering from subcutaneous attrition of the femoral artery received from an accident. When examined a voluminous blood tumour was discovered in the inguinal region, and pulsation had ceased in the tibial artery. It was that fact which enabled him to make the above diagnosis.

Towards the fifth day, the foot had become cold, and gangrene being imminent, the speaker decided on opening the tumour and laying bare the femoral artery. When the vessel was brought to view it was found to be black in colour for the space of three inches, and evidently filled with clots. Having placed a temporary ligature above the lesion, he opened the artery longitudinally, removed all the clots and closed the wound with sutures. For several days great hopes were entertained, but finally the foot became cold again, gangrene set in, and the leg had to be amputated. He asked himself if, in spite of the apparent success, the operation had not been of some utility in arresting the extension of the gangrene, which otherwise might have gone higher up.

M. Delorme replied that when an artery suffered in the way described by the foregoing speaker its internal surface presented numerous irregularities which could not be removed by an operation like that practised by M. Legars, and that condition sufficed to determine the

reproduction of clots and the obliteration of the vessel. Consequently he did not consider that any operation could benefit the situation.

RECURRENT HÆMOPTYSIS.

Hydrate of Chloral, 3ss;
Bromide of sodium, 3j;
Syr. of orange, 3j;
Water, 3v.

A tablespoonful every two hours, and continued for a week. The hæmorrhage ceases towards the second day.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, May 31st, 1902.

At the Surgical Congress Hr. Riedel, of Jena, gave a communication on the

TREATMENT OF HÆMORRHOIDS.

For a long time he used the actual cautery, but found bad results sometimes followed— even fatal hæmorrhage—so that he gave it up. He then carried out extirpation and suture of the external skin to the mucous membrane, and in two cases stricture followed. Extirpation, moreover, was a very tedious operation. He therefore gave that up. Since then he had carried out another procedure, in which from within outwards, in a radial manner, a number of sutures were applied about $\frac{1}{2}$ cm. apart. No hæmorrhage followed, and complete obliteration took place. The after-treatment was simple. He had operated in this way in thirty-two cases, and no disturbance and no formation of stricture followed. Recovery was complete in three to four weeks. Occasionally there was slight prolapse of mucous surface.

Hr. Sendler was in favour of the cutting operation. It was very simple, and the mucous membrane was sutured to the skin of the anus.

Hr. Brantz thought one operation would not suffice for all cases. The operation must be adapted to the site of the hæmorrhoids.

Hr. Kocher, Bern, did not perform excision any longer on account of the disturbance set up by the cicatrix.

Hr. Lavil, Bern, spoke on

THE ACTION OF ANTI-STREPTOCOCCUS SERUM.

He referred to experimental and clinical observations he had made with it. The action was a simple anti-bacterial one, not anti-toxic, as he had satisfied himself by experiment. As to his clinical observation, in eleven cases of sepsis improvement took place in 50 per cent. In twelve cases of erysipelas a curative effect was exercised in seven cases, one case of scleroma recovering. Three cases of meningitis, one recovery; eight cases of pneumonia, all recovered; two of tuberculosis, both improved; three of phlegmon, all very much improved. The effect of the serum was not confined to streptococcus infection; it was useful also in staphylococcus infection. In a large number of cases the action was striking sometimes it was slow, while in other cases no effect whatever could be discerned.

Hr. Heidenhain, Worms, then spoke on

INTESTINAL CLOSURE AND ENTEROSTOMY IN PERITONITIS.

He was of opinion, judging from his own experience, that in peritonitis occlusion of intestine not unfrequently took place. In cases of intestinal distension with

vomiting he had performed enterostomy, with recovery in four cases. By enterostomy time was gained for return of function to the paralysed intestine.

Hr. Sprengel, Brunswick, was not inclined to look upon the operation with any favour, but Hr. Kocher, of Bern, considered Heidenhain's communication to be very encouraging.

Hr. Conrad, Brunner, spoke on some

EXPERIMENTAL INVESTIGATIONS ON PERITONITIS CAUSED BY STOMACH CONTENTS.

The stomach contents were injected into the peritoneal cavities of animals. In most cases there was a mixed infection. In the healthy stomach even, there were always pathogenic microbes upon which the acid gastric juice acted harmfully. In diseased stomachs their number was greater. He had investigated the degree of infectiousness of stomach contents. He introduced 1 ccm. acid gastric juice into the rabbit's stomach. With small quantities the animals did not die until 50 ccm. had been injected. All other animals remained healthy even when large quantities had been introduced. When the acid of the juice was diminished in quantity, however, the animals quickly died of acute peritonitis. The virulence of the microbes was diminished by the acid of the gastric juice. It was the same in his opinion with the human subject, and this was of great importance in operations on the stomach. Thus in carcinoma of the stomach with but little acid in the gastric juice the escape of stomach contents was very dangerous, much more so than when there was a normal degree of acidity in the contents of the stomach. He had repeatedly tried the effect of washing out the abdominal cavity with normal saline solution after escape of gastric contents into it. Such washings out were generally practised by surgeons after operation in perforative peritonitis. The experiments were made in such a way that certain measured quantities were injected into the peritoneum, and after being dispersed over the whole abdomen they were removed again. When acid streptococcus stomach contents were injected 5 to 15 ccm. were certain to prove fatal. Some of the animals were improved at first by washing out, but they all died in the end. Injections of acid stomach contents were made up to 40 ccm. and the results were more favourable. Some of the animals died but some were saved by the washing out.

Hr. Marx, Lubeck, read a note on

THE ACTION OF QUININE ON ANIMAL TISSUES.

An agglutination of bacteria was caused by quinine. It had also an action on the corpuscular elements of human blood, it agglutinated the red blood corpuscles, and led to clotting. Subcutaneous injection of a 1 to 2 per cent. solution caused local necrosis. Clinical experience taught us that a tampon soaked in a 1 to 2 per cent. solution of quinine arrested hæmorrhage at once. If quinine in powder were sprinkled upon tuberculous granulations, in twenty-four to forty-eight hours the granulations were converted into a grey mass under which was found a healthy non-bleeding wound surface. Löffler had proposed to treat carcinoma by the injection of malarial blood, on account of the supposed rarity of cancer in malarial countries. This immunity, if there were any, was due to the extensive use of quinine in these countries. Quinine was a powerful antitoxin against the cellular blood-poisoning

elements, and especially against plasmodia. Possibly for this reason it was useful also in carcinoma.

The *Deutsch. Med. Zeit.*, May 19th, has an address delivered by Hr. Beyer on

SOLUBLE SILVER,

a very powerful antiseptic. He said the more silver could be introduced into the system at once, the more intense and certain was the action. Many failures resulted from non-observance of this rule. The action of the silver was rather arresting than destructive. For this reason the body had to be kept under its influence for some time, especially when new infections were taking place. The silver was excreted quickly. It could be introduced slowly by inunction, and more quickly by intravenous injection.

Hr. Crede used a $\frac{1}{2}$ to a 1 per cent. solution for intravenous injection. Before using it he filtered it or let it stand awhile, and then drew up into the syringe only the upper clear part of the solution. The prompt and specific action of these injections was from his own recent observations indisputable, so much so that in grave sepsis and allied diseases he should urgently recommend them.

DEATH OF PROFESSOR KUSSMAUL.

Professor Adolf Kussmaul, the well-known physician and author, died last week at Heibelberg from the effects of an attack of asthma. Among his services to medical science was the introduction of a greatly improved stomach pump, and of the operation known as thoracocentesis. He published an important work on epilepsy, which greatly promoted the study of that disease.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, May 31st, 1902.

MAYDL'S OPERATION.

At the "Gesellschaft der Aerzte," Frank showed a young man, æt. 18, on whom he had operated four years ago for epispadias. At that time he performed Maydl's operation by conducting the ureter into the rectum, which he considered a perfect success, as the patient is now able to retain his urine in the rectum with perfect comfort for five hours at a time. The epispadias was repaired by a plastic operation which has quite restored the generative functions.

Eiselberg said that he had now operated in eight of these cases by Maydl's method, but had lost three of them, a mortality of 37·5 per cent. In two of these fatal cases the plastic operation could not be performed without a good deal of tension on the ureter, which apparently induced necrosis, peritonitis, and death. The third case was more interesting. A young woman with well-developed healthy genitals became pregnant, and the enlarged uterus so pressed on the ureters that he considered operation necessary to relieve the compression and he conducted them into the rectum. Subsequently the sphincters of the ureters in the bowel became closed, and the woman ultimately died of pyelitis. The other five were perfectly successful and could retain their urine any normal length of time without any inconvenience, neither was there any kidney affection, although five years had

elapsed since three of the operations had been performed.

Frank replied by saying that he had operated in two other cases, one of these a mere child, with the best results.

CAUSTIC SODA DERMATITIS.

Ehrmann showed a young man with a peculiar skin affection on the back. He presented a punctiform efflorescence which was florid in the periphery and covered in the centre with a dark scurf, while further out was a red, inflamed surface. His duty was to carry bags of caustic soda in the transportation of this chemical. He found on investigation that a large number of the workers were similarly affected. On closer examination of the subject he found that the lesion was due to an electrolytic action producing fine crystals of caustic soda, which penetrated the clothes and became deposited on the skin. This fine powder seems to have finally entered the sweat ducts, and produced the present eruption.

Kreiblich related two similar cases he had produced with a soap ointment, which often deposits these fine crystals.

ZUCKERKANDL'S SYMPATHETIC BODIES.

Biedl next read a paper to the Society on the bodies found by Zuckerkandl in the new born, lying along the sympathicus. These are bilateral bodies lying in the retroperitoneal region, on both sides of the aorta extending below the part where the inferior mesenteric artery is given off, and serving some intrauterine purpose. They are small, light-brown in colour, and measure from 8 to 11 millimetres, or 0.31 to 0.42 of an inch, and have the consistence of a lymph gland; frequently one end is united with another, forming a sort of isthmus, while the uppermost are frequently connected with small tubercles above. On account of their proximity to the sympathetic Zuckerkandl has called them the "Neben-organe des sympathicus." They are well supplied with a network of vessels whose principal artery is derived from the aorta itself, while its vein discharges into the inferior vena cava. There is a fibrous capsule composed of a thick net of capillaries, in the meshes whereof are found large polygonal cells that take up the chromates with great avidity, acquired a well-marked yellow-brown colour, which have already received the name of "chromophile" or "chromaffine" cells, as such cells are only to be found in similar positions such as the suprarenal bodies. They lie close to the sympathetic ganglia, measuring in a foetus about twenty-eight millimetres or one inch in length. The tubercles in connection with them above do not take up the chromates, and are therefore not chromaphilic.

If this sympathetic body be rubbed up with powdered glass and mixed with a physiological solution of salt, and then injected intravenously into dogs, guinea pigs, or applied to cat's heart laid bare, the same physiological result will be obtained as when a solution of the suprarenal bodies is used, viz., an immediate rise in the arterial pressure, while the pulse will be slow and arrhythmic; but after vagotomy this slowed condition of the pulse is immediately removed. This blood pressure is associated with a constriction of the spleen with a peripheral vascular spasm; by tying the four arteries of the brain and cutting off the vaso-constrictor centres the extract has no effect. This organic extract is different to the

suprarenal in its action, as it sometimes quickens the pulse with arrhythmia. The action of the extract on the muscular tissue is best shown on the cat's heart; it seems to stimulate as the pulse volume is increased, but by repeated applications the heart's action is seriously affected, the right side giving way first, followed by the left. The three foetal organic extracts agree in their action on the organism and their behaviour with chromium salts, all of them raising the blood pressure and stimulating the heart's action.

CARBUNCLES.—TREATMENT.

Bidder proposes to shorten the progress of a carbuncle by injecting a 2 per cent. solution of carbolic acid into the fibrous surroundings and subsequently covering with plaster. After this there is considerable pain, but the abortion of the carbuncle is remarkable.

The Operating Theatres.

ST. MARY'S HOSPITAL.

CASE OF AMPUTATION AT THE HIP-JOINT FOR SARCOMA OF THE FEMUR.—Mr. STANSFIELD COLLIER operated on a man, *æt.* about 22, who had been sent from the West Indies, a diagnosis having there been made, after incision, of sarcoma of the upper part of the shaft of the left femur. The patient, who was extremely emaciated, was suffering intolerable pain. There was a very large tumour surrounding the upper half of the shaft of the femur and extending to the hip-joint. The pain was referred more especially to the region of the knee. Four hours before the operation 30 grs. of calcium chloride in solution were injected into the bowel. An incision was made over the common femoral vessels, which were ligatured above and below, and large skin flaps were dissected up from the front and inner side of the limb. The muscles were divided as high up and as near the innominate bone as possible and the limb removed. It was remarked at the time that the oozing of blood, which was very abundant, very rapidly ceased, but the condition of the patient towards the close of the operation was extremely grave. Mr. Collier remarked that in such a case it was impossible to expect that the patient would be freed from the disease by the operation; this last was undertaken solely for the purpose of relieving the patient's sufferings. Mr. Collier had never seen a patient who lived twelve months after amputation for sarcoma of the shaft of the femur. In this case, moreover, he pointed out, one could see sarcoma tissue replacing the fatty pad in the floor of the acetabulum; and even if the condition of the patient had been less collapsed it was very unlikely that one could succeed in excising the whole of the affected area. The ligature of the femoral vessels had not been as efficacious as usual in limiting the loss of blood; this, he said, might be explained by the extent to which it had been necessary to cut away the gluteal muscles. The rapidity with which the hæmorrhage from the smaller vessels came to an end was, he considered, to be explained by cardiac failure rather than as being the result of increased rapidity of coagulation from the use of the calcium chloride, which, however, might have been a factor. After the operation a saline and brandy injection (two ounces of brandy in two pints of normal saline, at a temperature of 105°) was made into the left median basilic

vein and the patient as quickly as possible removed to bed; the condition of collapse persisting, the limbs were held vertical for some hours. The patient appeared to be in a dying condition during thirty-six hours, but quite unexpectedly rallied. Some twenty-four hours after the operation he complained of frightful agony in the left hand and on examination, both the hand and forearm were found to be swollen and cold; no radial pulse could be found on this side, but as his pulse could with difficulty be felt in the right limb, it was thought that the oedema prevented it being felt in the left limb; no thrombosed veins could be felt on this side, but it nevertheless appeared that thrombosis of the chief veins existed; during the next few days the swelling gradually disappeared, and the circulation was restored, excepting in the skin of one finger tip, which sloughed. The healing of the stump was uninterrupted, and the patient, six weeks after the operation, is free from pain and putting on flesh. Examination of the limb after removal showed a subperiosteal sarcoma of enormous size, with replacement of much of the bone by growth with a curious sarcomatous infiltration of the ligamentum teres. In a subsequent ward visit, Mr. Collier expressed his surprise that the patient had rallied, he was inclined to explain the ischæmia of the left upper limb as being the result in large part of a venous thrombosis; venous thrombosis so rarely followed intravenous injection that it was likely that the presence of calcium chloride in excess in the blood was the determining factor in the production of the thrombosis. There was not the smallest evidence of sepsis of the injection wound.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page 22 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 4, 1902.

THE GENERAL MEDICAL COUNCIL.

THE bone of contention between the Council and the Royal Colleges of London having been removed at the recent special session, the Council was able to start fair on the perennial question of preliminary examination, and to discuss some interesting points in respect of the professional examinations. Some painful penal cases came up for the judicial con-

sideration of the Council, several of them being of a nature to require the evidence being given *in camera*. We note, indeed we welcome, a disposition on the part of the Council to take official cognisance of what we may term immorality in a professional respect. Hitherto, complaints based on the non-criminal immorality of registered practitioners have virtually been ruled *ultra vires*, but it has dawned on the Council that certain departures from morality, when indulged in under the professional mantle, are more detrimental to the public estimate of the profession than a host of comparatively mild offences such as assault, drunkenness or what not. Obviously the Council has nothing to do with questions affecting the private morality of practitioners, but it is otherwise when offences against the moral law are also outrages on the ethical precepts regulating the calling of medicine.

THE ELIMINATION OF THE "CHRONICS."

We owe to Dr. Ball a valuable suggestion having for object to cut short the career of the "chronic," this opprobrium of the pupillary stage. Before dealing with him it is necessary for the Council to be able to "spot" him, and additional information is to be obtained from the various licensing bodies bearing on the number of repeated rejections. Incidentally attention was called to the importance of securing uniformity of treatment at examination in respect of special subjects or groups of subjects. Some examining boards allow candidates to pass examinations piecemeal, while others either do not or only do so in a very restricted sense. This "equalisation of rates" is such a reasonable suggestion that there ought to be no difficulty in its adoption. One way of eliminating the "chronic" would be to increase the period of reference at each successive failure, so that at a third failure for a particular examination the term would be of such duration as effectually to deter the candidate from presenting himself until he was fairly sure of success. At present too many men present themselves on the "off chance," and some of them scrape through more by good luck than merit. Though this suggestion has much to commend it, its application is likely to meet with some opposition by the licensing bodies in view of the loss of fees which it would entail. There is one point to which it is surprising that attention has not been directed while the question of uniformity of examination is under consideration, viz., why it is that so large a proportion of students from Ireland and England—we put Ireland first because the greater number hail from that part of the kingdom—find it worth while incurring the expense of going to Scotland for a qualification when so many portals are open nearer home. There can be but one explanation—at least, we are unable to discover any other—and that is the greater facility with which certain qualifications can be obtained. The Council's visitors and inspectors are dumb on this point although one would expect it to have engaged their attention long since.

COUNCIL FINANCE.

The distressing financial plight of the Council, which Mr. Victor Horsley has brought into prominence, has been investigated by a committee whose report will be found, *en resume*, in the proceedings. This report shows the financial position to be parlous, and it behoves the Council to lose no time in putting its house in order. Of the various alternatives presented to the Council with the restoration of financial equilibrium in view, those which command its approval are, in the first place, a registration poll tax on students to the tune of a pound apiece. With regard to the general practitioner Mr. Horsley favours the imposition of a yearly payment similar to that exacted of solicitors; but the Council, never very partial to Mr. Horsley's suggestions, decided in favour of raising the initial registration fee from £5 to a sum "not exceeding £10." No doubt it will be found easier to "squeeze" students and neo-practitioners than to apply the thumb-screw to the general body of practitioners, and, subject to Parliamentary approval, we may look to these two categories of victims to supply the deficiency. Incidentally, no doubt, the request to Parliament to be authorised to impose a registration fee on students will entail the right to enforce registration, a right which has been seriously called in question of late. This fact alone ought to rally supporters to the proposal. With respect to the other proposal Mr. Horsley's policy appears by far the best. The imposition of a small yearly payment would greatly promote the accuracy of the *Medical Register* in that deceased practitioners would fail to respond, and would therefore automatically disappear from the list; practitioners who have failed to notify change of address would sink into oblivion, and the personation of deceased practitioners would also be rendered more difficult. The Council, however, prefer to surcharge the man who, with all his blushing honours thick upon him, is not likely to kick at an extra five pounds. Without committing ourselves to the conclusion that the expenditure of the Council is invariably of a useful and productive character it does not appear that any tangible economy can be effected in respect of the working expenses of the Council, short of reducing its unwieldy number. The present financial crisis offers an exceptional opportunity for cutting down the representation accorded to licensing corporations by giving them one "class" representative per division of the Kingdom, instead of one apiece. The duplication of expensive machinery in the shape of Branch Councils is to be abolished, as it should be; in fact, we are evidently on the eve of far-reaching organic changes.

THE MEDICAL DEFENCE UNION.

THE annual report of the Medical Defence Union presents the record of solid achievement in

the past and of hopefulness for the future which are accustomed features of the work of that Society. That the affairs of this organisation for self-help have been conducted with prudence is abundantly evident from the results of the legal actions defended on behalf of members during the past twelve months. More than a thousand cases have passed through the hands of the general secretary, and in only one of the cases which resulted in actions at law was an adverse verdict registered against the Union, and that only on technical grounds. Apart from the actual protection afforded to individual members, the interests of the medical profession generally have been materially advanced in various directions, more especially by representations to the General Medical Council. The Defence Union has firmly adopted the principle that canvassing and advertising for patients, whether done in the interests of a company or the personal interests of medical practitioners, holding a private club, must be stopped at all costs, as against public policy and professional morality. In pursuance of that definite ground of action the Union has during the year under report rendered various valuable services to the profession. Perhaps the most important was the disappearance of the Birmingham Consultative Institute, following closely upon the resignation of Dr. Irvine as medical officer. The main objection to the scheme of the Institute in question was that it offended all professional decorum, because it could have been carried through only by a system of wholesale canvassing and advertisement. The other great judicial success of the Society was secured in the attack upon the Medical Aid Societies, which for so many years past have exploited the services of medical men with a view to making a profit for what are nothing more nor less than trading companies. The bold action of the Medical Defence Union in the Great Yarmouth case has been followed by the wholesale resignation of practitioners holding such appointments. Under the circumstances it is clear that the medical aid societies will find it difficult or impossible to fill the vacancies. The report of the energetic solicitor to the Union, Mr. Hempson, emphasises the fact that it is the impecunious litigant whom the medical man has most to fear. He further points out that in his opinion that of all professional men the medical practitioner was the one almost invariably selected for speculative actions. The unsuccessful action against Dr. Law resulted in his having to pay costs to the extent of £700. Considering the vast advantages, both individual and general, that have been conferred upon the profession by the Medical Defence Union, it is hardly satisfactory to note that its membership roll does not exceed 5,000, that is to say, less than one-seventh of the registered medical practitioners of the United Kingdom. We would strongly urge every medical man who is not already a member of the Union to lose no time in effecting insurance against manifold dangers, to be secured at the cost of a trifling annual subscription to this most valuable and energetic Society.

THE HOUSING OF THE WORKING CLASSES.

It is admitted on all hands that the problem of providing healthy dwellings for the working-class inhabitants of our large cities is one of extreme and urgent importance, but the interests concerned are so numerous and considerable as hitherto to have baffled any drastic reform. The problem comprises two related but distinct matters: one is the provision of salubrious dwellings at rents within the reach of the class for which they are intended, and the other bears on the demolition and reconstruction of slum property. A numerous and influential deputation was received by the President of the Local Government Board last week to urge the simplification of the procedure for dealing compulsorily with slum properties and for compulsorily acquiring sites for the erection of suitable dwellings. Mr. Long lent a sympathetic ear to the delegates, but he warned them that the subject was one of exceeding complexity and peculiar difficulty. No doubt the delegates have been made aware ere now of this fact; indeed, the object of their interview was precisely to ask the assistance of the Government in removing the more obvious of the hindrances to reform. Mr. Long, though he agreed that the owners of slum properties ought to have pressure brought to bear upon them, did not display any great desire to assist in making this possible. His views were not characterised by any broad, statesmanlike grasp of the situation, and the sacredness of vested interests is still allowed to thwart the desire of great municipalities to be allowed to take the matter in hand in the only way which promises an issue out of the present unsatisfactory position of affairs. Mr. Long is not disposed to promise Government support to the proposal to dispense with the costly and cumbrous plan of appealing to Parliament for power to compulsorily acquire land for rehousing purposes; at most he timidly hoped that means might be found to lessen the cost of such appeals. It must, of course, be borne in mind that a scheme for rehousing does not necessarily imply the construction of houses in the centre of densely populated cities. In cities of moderate dimensions relief may probably be obtained by developing the means of rapid and cheap communication, but this alternative can never afford more than partial relief in the metropolis, for the simple reason that certain callings entail the presence of the labourer within easy reach of his work, and in London the distances to be traversed are such as to minimise the advantages of even abundant means of transport. Thanks to a mediæval system of land tenure, and to artificial technical difficulties in the way of utilising the available space, *plus* unduly onerous financial regulations, the best intentioned efforts are frustrated, so that year by year the problem becomes more acute. The matter is eminently one for Government initiative. There has been ample time to study the problem in its various aspects, and there is really no excuse for further delay.

Notes on Current Topics.

Reward for Distinguished Service.

LIEUT. WILLIAMS, M.B., I.M.S., has received the ribbon and cross of the Distinguished Service Order for distinguished service with the Chinese Expeditionary Force last year. He received his medical education at Dublin University and the Royal City of Dublin Hospital. The details of his services are as follows:—In April of last year the general in command at Shanghai-Kwan heard that a force of Boxers had assembled near Funing. He ordered a force, under Major Browning and Lieutenant Sterling, D.S.O., with Lieutenant Williams in medical charge, to proceed to Funing and reconnoitre. On the morning of April 20th they met and were attacked by a force of 1,000 Boxers. Major Browning was shortly after killed, and Lieutenant Stirling was wounded in the neck and foot, with the result that Lieutenant Williams had to assume command. After fighting for several hours the force fell back, and held Funing till relieved by British and Japanese troops. On April 22nd Lieutenant Williams was again in medical charge of 1,000 troops, British, Japanese, and French, which proceeded to Tai-cao-Ying, storming and capturing it, and dispersing the Boxers. We congratulate Lieut. Williams on his well-deserved reward. The services he rendered on that occasion serve to throw into strong relief the absurd contention of certain officials of the War Office that the army medical officer is primarily, secondarily, and perpetually a civilian, and that he must be treated accordingly.

The New College of Science for Ireland.

As usual, the Government appears to have made what is commonly known as "a mull" of the arrangements in connection with the selection of the site for the new College of Science in Dublin. The second reading of the Public Offices (Ireland) Bill was passed last week, and during the debate upon it, it transpired that the Government has become possessed of such an *embarras de richesses* that it does not quite know what to do. In the first instance, the Government acquired a site adjoining the National Museum and Library between Upper Merrion Street and Kildare Street on which to build the College. As, however, a building so placed would be completely shut out from public view, it determined to acquire houses in Merrion Street, the removal of which would clear a frontage. Now, unfortunately, it finds that the houses it has selected are among the best in Dublin, and that it would be an act of vandalism to pull them down. Accordingly, they are to be turned into Government offices, and the College of Science is to be again condemned to an undeserved obscurity. It is undoubtedly a very great pity to have to condemn houses such as those in Upper Merrion Street, but we confess we consider that it would be a still greater pity to shut out a large portion of what ought to be a magnificent block of public buildings. Of two evils, it is better

to avoid both, but when Mr. Austen Chamberlain's predecessors have driven us upon a choice, we should prefer to refrain from masking the College of Science.

Kissing the Book.

IN many instances the tyranny of custom is able to set at defiance the teachings of progressive science. No more flagrant instance of this sort of inconsistency could be cited than the unwholesome practice of administering the oath to witnesses in a court of law by the ceremonial known as kissing the book. At this time of day it would be superfluous to dwell upon the dangers incurred by witnesses who carry out that superstitious rite. Any intelligent man who watched for a single morning the hands and lips that come in contact with the book used in a busy police court would realise to the fullest extent the force and cogency of the scientific condemnation of the practice in question. The fact that Scotland has never been persuaded to adopt this most unwise practice of the Southron reflects favourably upon their sagacity. In the course of time, perhaps in a century or so, the abolition of the testamentary book from our law courts will certainly become an established fact. The Oaths Act, as every responsible inhabitant of the United Kingdom should know, entitles every witness to take the oath with uplifted hand, as usually administered in Scotland. In order to secure his further protection the Act specifically directs that at his request the oath shall be administered to him in such form and manner without further question. The judge has no right to ask what are the grounds of the request, nor, indeed, to make any comment of any kind whatever. The Scotch form is an oath, and not a simple affirmation, and may be substituted for any form of oath that can be legally administered in any court of the United Kingdom.

Proposed Irish Coronation Commemoration Project.

THE question, as to what is the best means of commemorating in Ireland the Coronation of His Majesty King Edward VII., has been under discussion at several public meetings, which have been lately held in Dublin. Two proposals stood out prominently in public favour above all others. The first of these was to raise a fund for the relief, by grants or otherwise, as far as the annual income will admit, of necessitous aged, sick, or disabled medical and surgical female nurses working in Ireland, to be called "King Edward VII.'s Coronation National Fund for Nurses in Ireland." The second, with which the name of the President of the Royal College of Physicians was associated, was to raise a fund for the purpose of erecting an additional wing to the National Consumption Hospital at Newcastle. After a long discussion the former of these two projects was chosen. Both schemes are admirable. The former is the more ambitious, and the one which will perhaps more widely commend itself

to the medical profession. The latter is the more simple in its evolution, and the one which will not entail the collection of so considerable a sum of money. Both schemes are, it is needless to say, absolutely unsectarian. The choice of the Committee will insure that, if sufficient money is collected, an important step will have been taken to remove the reproach which lies heavily on the community in general, the reproach that they on whom in great part we depend and on whose aid we lean in sickness, and to whose care and devotion the lives of thousands are due, are the very persons most frequently left in their old age to struggle along it may be in actual want. If sufficient money can be collected, the Committee could not have selected a better scheme, and we are confident that the public will see to it that sufficient money is collected.

A Case of Quintlets.

OUR tri-lingual contemporary, *The Sei-I-Kwai Medical Journal*, contains in the last number to hand an interesting report of the birth of quintlets, which occurred in Japan in the practice of Drs. M. S. and M. N. Sato. The patient, who had been married at fifteen, had borne eight children previously. In the present instance she had been apparently pregnant for eight months when labour ensued, but the abdominal enlargement was much greater than it had ever been at full term in previous pregnancies. The first foetus—a boy—was born at 8 p.m.; after four minutes a second foetus—a girl—was born; after another five minutes the third foetus—a boy—was born, followed by a common placenta belonging to the first two children. After another five minutes a fourth foetus—a girl—was "delivered by the foot;" and common placenta for the third and fourth children was expelled. Then, the medical men considering that they were attending a case of quadruplets, and "having washed the stained hands," examined the abdomen, only to find that there was still something inside the uterus, and with some little help a fifth foetus was delivered, followed by its placenta. The entire time occupied by the delivery of all the children was thirty-five minutes. All were premature and very weak, and died within a couple of days.

The American Medical Association.

THE meeting of this association, which is to take place at Saratoga next week, promises to be a big thing, if we are to judge by the "preliminary programme" which has been put forward. From it we learn that the work of the meeting will be undertaken by twelve sections, and that before these sections 368 papers will be read, nine addresses of chairmen will be delivered, and six discussions will be opened; while for the sustenance of those members who require some more nourishing pabulum than the foregoing, two *symposia* will be held, one on epilepsy, the other on carcinoma. The range of subjects which will be brought before the association is practically infinite, and those whose intellect

survives will, we are sure, be vastly instructed. The subjects range over every possible field, from the modern treatment of gun-shot wounds to the use of "The goat in ancient and modern medicine and therapy." Seriously, though, we cannot but think that the American Medical Association would have been wise if it had delegated to a Committee the duty of selecting the papers which were to be laid before the meeting. The duty would not be a particularly pleasant one, but it would at any rate have the effect of ensuring that important subjects would receive the prominence they require, and that time would be afforded for their discussion.

Low-flash Oil.

THE accumulated evidence as to the agency of low-flash oil in causing a large number of fatal fires has not hitherto been met by any corresponding essay of the Legislature. Indeed, the tendency of the present Government has been decidedly hostile to any such legislative interference. In answer to a member of Parliament, the Home Secretary, Mr. Ritchie, has stated officially that he is not convinced that such action would be effective in preventing or seriously diminishing the class of accidents in question, or that there would be sufficient justification for its introduction. The grounds of this conclusion are not clear. Either low-flash oil is or is not a danger to the community from the unnecessary fires due to its extra inflammability. A vast number of fires occur every year in all parts of the United Kingdom in which the lamps concerned have been fed by low-flash American oil. If the use of oil of higher combustion point will add to the safety of the lives and the property of the population of the British Empire, then it seems clearly the duty of the Government to supply that additional safety. Apart from loss of life, the property destroyed by these preventable low-flash fires has to be borne by the community. As things stand, there appears to be some reason in the assertion that this national sacrifice of life and property merely puts money into the pockets of an American trust who are permitted to palm off a vast amount of inferior stuff upon the British market. The issue is too serious to be dismissed contemptuously with a few official generalisations.

Vacation Schools and Playgrounds.

OUR methods of work and manner of play stand in need of much modification. We are slowly learning the wisdom of adopting many procedures which our American cousins have proved to be of service in securing a higher degree of physical welfare. The concentration of our people in towns and cities is rapidly leading to the establishment of conditions inimical to child life. It is therefore incumbent on all to realise that national efficiency can only be maintained by providing better means for the physical and mental growth of the children. This matter is the subject of a valuable paper which appears in the June number of *Harper's*. It is shown that play

is an essential for the child. Play means to the developing human the rapid acquirement of physical adjustments and correlations through movements made easy by the long history of the race; it means the awakening of the intellect through agents which are by heredity most stimulating; it means the merging of consciousness of self into interest in activity; it means action which is permeated by intense thought; hence it means the addition of grace to all action, for grace is the outcome of play, and no activity is ever graceful until it becomes play, or, in other words, is done for the pleasure of doing it rather than for results. The biology of play is deserving of serious study. And the practical application of play as a prophylactic and remedial agent should receive full investigation. We may now soon expect the enervating action of excessive heat, when work in rooms and toil in towns becomes a burden to mind and a tyranny to body, and when the deleterious effects of confinement bears with heavy weight on the children. It is therefore wise that we should avail ourselves of those alleviating agencies which our brainy cousins across the Atlantic have proved to be so beneficial and so widely appreciated. We commend this subject of the establishment of vacation schools and playgrounds to hygienists, educationalists, and all interested in the service of the children in this country.

"Blown" Tins and Preserved Food.

THE present generation has witnessed an immense development of the tinned food trade, which now embraces meat, fish, fruit, vegetables, and other edible products. With this fresh convenience in the feeding of our insular population there has arisen a new danger to health by way of various bacterial forms of poisoning. As a matter of bald statement it may be remarked that any canned food which is not sterilised together with its receptacle at the time of packing constitutes a probable serious after-dinner danger to the health of the consumer. Fortunately, decomposition generates almost if not quite invariably certain gases which greatly increase the pressure inside the tin, which is thereby "bulged" to a compensatory extent. This bulging or "blowing" of the tin enables the sanitary inspector to recognise most forms of unwholesome tinned food at a glance; Should, however, the metal case be strong enough to resist the internal pressure the accumulation of the gas may still be detected by a judicious process of percussion. One of the greatest rocks ahead in the detection of the fermented foods is presented by the roguery of dishonest dealers who prick the can to let out the gas and then solder up the aperture. Last week, in the Southwark Police Court the Medical Officer of Health testified that he had seen thousands of tins of milk that had been thus resoldered for sale to the public. It is to be hoped that sanitary authorities throughout the kingdom will become fully awake to the dangers arising from the preserved food trade. Speaking generally, there is room for a great increase of activity in the ad-

ministration of the Acts passed with a view of protecting the purity of the food of the nation.

Nursing Homes and Nursing Hells.

UNDER this sensational title *Truth*, the indefatigable, describes a very unsavoury specimen of a so-called nursing home, and on the strength of this instance formulates some very sweeping charges, culminating in an appeal for official inquiry and control. In the instance in question imbecile, aged, and bedridden persons were received at prices varying from twelve shillings to a guinea a week. It is self-evident that in exchange for such payments it must be impossible to provide proper care or, indeed, proper anything. It is argued that, as asylums for lunatics and baby-farming establishments are kept under strict supervision, similar provision ought in justice to be made for the aged and helpless, and with this conclusion we are not disposed to quarrel, although we cannot exonerate the persons who deliberately or negligently leave their aged or infirm relatives in such "homes" from a large share in the responsibility. The extraordinary development of nursing home institutions during the last ten or twenty years has unquestionably led to some being carried on in houses absolutely unsuited for the purpose, and, since they are one and all run on purely commercial lines, it is evident that expenditure on structural alterations will, as a rule, be reduced to a minimum. Apart from mere structural unsuitability, we believe that the vast majority of nursing homes, certainly at any rate those with which we are acquainted, are conducted on humane and scientific methods, indeed they would have little chance of success were it otherwise, since the reputation of the physician or surgeon is in large measure dependent on his success, which would be imperilled were he to consign his patient to inadequately staffed or improperly conducted homes. Here, however, the fees demanded are sufficient to allow of an adequate measure of comfort and skilled attendance. It is quite otherwise with regard to many "homes" for the infirm, the aged, and the bedridden invalid. It is necessary therefore to distinguish between the two classes of institutions, though technically the differentiation presents extreme difficulty. It would certainly be in accordance with modern ideas to insist on a certificate of structural fitness being obtained before any one should be at liberty to convert a dwelling-house into a nursing home. As to inspection, this, except in respect of sanitary arrangements, is inadmissible. There is no particular objection to the registration of nursing homes, but on the other hand we fail to see what useful purpose would be achieved thereby. Such a "home" as that described by our contemporary constitutes a standing nuisance, and would thus come within the purview of the medical officer of health, a simple complaint providing sufficient ground for his interference. It scarcely seems worth while to elaborate an irksome system of control in order to prevent abuses which are capable of amend-

ment under existing provisions. *Truth* has discovered a nightmare—we mean a mare's nest—not, indeed, that our contemporary's strictures are not amply justified in the instance, but that the conclusions, based on the *ex uno disce omnes* principle, are wide of the mark.

A Lunatic Sent to Prison.

THE need of some plan for the skilled medical supervision of police-court verdicts in cases of possible lunacy has long been apparent. There can be little doubt that under the present system a great many unfortunate persons have been sent to prison when their proper destination should have been the lunatic asylum. An instance of this kind was forthcoming during the course of last week's proceedings in Barnet Police Court. A woman of sixty years of age was charged with persistently annoying a former pupil at her dancing classes in the person of a man whose age was given as thirty-four. The defendant was love-sick, and showered letters upon the plaintiff containing multitudinous protestations of love and proposals of marriage. The medical evidence is said to have been to the effect that the defendant was not insane, but was labouring under a delusion with regard to the plaintiff. It is hardly conceivable that an opinion of that contradictory nature came from any authoritative medical source. Finally, as no surety was forthcoming on behalf of the defendant, she was sent to gaol for a month, and the glory and honour of the British Constitution thereby vindicated. The poor woman on leaving the court remarked, "It's a disgrace to the country I should be sent to prison." Most candid and thinking persons will agree with that pathetic protest. To send an unfortunate elderly spinster suffering from mental illusions to herd with criminals in a common gaol is worthy of the darkest and blackest periods of early and mediæval history. We beg to call the attention of the Home Secretary to this gross miscarriage of justice.

The Restoration of the Inebriate.

ON Friday, May 30th, a party of medical men paid a visit of inspection, on the invitation of the authorities of the Salvation Army, to Victoria House, Thundersley, Essex, a new retreat for inebriates, and licensed under the Inebriates Acts 1879-1899. It is beautifully situated on the north bank of the Thames, 250 ft. above sea level, thirty-six miles from London, and six miles from Southend-on-Sea. It can be conveniently reached by a good service of trains from Liverpool Street to Rayleigh, two and a-half miles distant from the house. This fine old Essex mansion stands in its own grounds of about sixteen acres, and has been thoroughly renovated, and can now afford excellent accommodation for twenty-five male patients. Every medical man knows the extreme difficulty of dealing with an inebriate, and unfortunately financial considerations not infrequently add much to the perplexities of securing adequate treatment. We think

it well, therefore, that practitioners should know that inebriates can obtain admission to Victoria House for the very moderate charge of one pound weekly. Applicants must of course agree to conform with the rules of the house, which exact a minimum of thirty hours of work per week, and be willing to remain under care for at least twelve months. Although conducted by the Salvation Army, we understand the institution is open to all and irrespective of religious considerations. When there is room monthly boarders are received at very reasonable terms. We venture to think that such an institution as this will meet a very distinct want, and the recent visit of a number of well-known medical men should do much to make its merits known to the profession.

The Pharmaceutical Society of Ireland.

DURING the past month this institution has taken legal proceedings in two cases, in both of which they were unsuccessful. Holding the important position the Society does, and charged with the duty of protecting the public against the illegal sale of poisons and the compounding of prescriptions by uncertified persons, such legal defeats have a very undesirable effect on the public. The Society has been sufficiently long in existence to know its legal rights, and no cases in which these rights are not infringed should be brought into court. Public opinion will support them in jealously guarding their many and great privileges; but if the public come to believe that, forgetting their position, they by groundless legal actions interfere with legitimate trading, their activity will be interpreted as trade envy. The law that regulates the business of the pharmaceutical chemist has, on all points that were at all open to doubt, been decided by the judges of the superior Courts. In the first case the decision was given on a legal point, which was held to rule the second case. We are, and throughout all their legal proceedings have been, prepared to support the Society in seeing that prescriptions were compounded by certified pharmaceutical chemists or other legally qualified persons. But when cases come before the Courts in which the commonest attention to the requirements of the statute on which their rights are based is wanting, we feel that the Society is endangering its reputation, and we feel disappointed that they do not exercise more care in the selection of their position before courting public and legal decisions.

The Physiology of Sleep.

It is a remarkable fact that concerning the phenomenon which occupies fully one-third of our lives, there should be so scanty reliable data that no satisfactory explanation has hitherto been arrived at. Sleep is often spoken of as twin brother of death. This, however, is mere poetic fancy. Sleep is, in fact, the most important means of repelling death. It is the Nature's great recuperative agent. It is essential to health and often forms the most vital factor in

the treatment of disease. And yet regarding the physiology of sleep we remain practically in the dark. Even what we may term the pathology of sleep throws but meagre light on its mechanism. A recent writer in our brilliant contemporary *The Academy and Literature* attempts to show that sleep is dependent on certain chemical processes where through the agency of carbonic acid the nerves are anaesthetised or reduced to immobility. Such a view has certainly much to support it, and what we know of the action of anaesthetics would not lessen the possibility of such being in some measure a probable explanation. The physiology and pathology of sleep stand in need of serious investigation. Accurate knowledge as to the best means of procuring sleep might then be expected to release us from the grasp of a limiting empiricism.

The Spread of Anthrax.

THE steady increasing number of cases of anthrax in cattle is a subject which may well engage the attention of veterinary surgeons and of the government department to which is entrusted the control of epidemic disease in cattle. It is pretty certain that many deaths of animals take place from anthrax without any intimation of the fact reaching the authorities, partly no doubt on account of the ignorance of farmers concerning the symptoms of this dread malady, but partly also to their irrdi-position to expose themselves to the worry and expense which the outbreak would entail. Every unrecognised case of anthrax constitutes a grave danger to the community, since in the absence of effectual sterilisation of the infected remains the disease is liable to be spread far and wide by garbage-devouring insects. Matters have not yet come to a pass which would justify extreme measures, but it ought to be possible to generalise information concerning the nature and mode of infection of the disease. Should milder measures not check the spread we may be asked to consider the practicability of enforcing the registration of cattle-death in the same way as for human beings.

A French Libel on Sir Michael Foster.

MR. HERBERT SPENCER calls attention to a ludicrous travesty of fact of which a writer in the *Revue des Deux Mondes* has been guilty in a review on a recent work of his. Mr. Spencer, in the work in question, mentioned incidentally, doubtless *pour rire*, that when Sir Michael Foster was a Parliamentary candidate for the University of London some tactless supporter urged his special eligibility for the honour on the fact that he (Sir Michael) was "such a good cricketer." On the strength of this absurdity the French reviewer solemnly states that the University of London had actually elected Sir Michael Foster because he was the best cricketer. It is perhaps pardonable that even a contributor to such an ancient and stately periodical as the *Revue* should be unacquainted with Sir Michael's scientific status, but that he should, in his ignorance of the

niceties of the English language, perpetrate such an enormity as this constitutes a misdemeanour calling for literary punishment.

The Corroding Effect of Alcohol on Instruments.

SURGEONS who use alcohol for the sterilisation of instruments will doubtless be interested in some experiments which have been recently made by Dr. Malmejac with the object of discovering the effect of absolute alcohol on metals. Dr. Malmejac in his experiments used 95 per cent. alcohol, which left no residue on evaporation. The metals—copper, iron, tin, lead, zinc and galvanised iron—were corked up with alcohol in glass flasks and kept at ordinary temperatures for six months. The copper was entirely unacted upon, but in all the other flasks there was a deposit on the bottom and the metal was covered with a similar deposit. In the case of tin, lead, zinc and galvanised iron the deposit was white; that from the iron was red, resembling iron rust. All of the liquids, except that in which the lead had been placed, filtered clear; the latter retained a milky appearance after repeated filterings through double filters. The clear filtrates from iron, lead, zinc and galvanised iron gave much residue on evaporation, while the residue from tin was hardly appreciable. In the former group it is clear that not only had the metal been oxidised, but a considerable quantity had entered into the solution.

The Stamping Out of Rabies.

Few persons will be found to dissent from the view expressed by Mr. Hanbury that "no loophole should be left for the spread of a disease so terrible as rabies." It follows that the muzzling orders must continue to be enforced until no trace of the disease remains in this country. It is satisfactory to note that the Government is disposed to treat as they deserve the complaints of those selfish people who resent any impediment being placed in the way of their trotting their canine pets backwards and forwards to the Continent. The people who are inconvenienced by the regulation imposing quarantine on dogs coming from abroad are few in number, but belong to a class of society which can make its voice heard, but it would obviously be a scandal to assuage their discontent at the risk of perpetuating rabies.

The Midwives Bill.

WE learn that Mr. T. P. O'Connor, M.P., will move an amendment to the Midwives Bill, which will come before the House on the report stage on Friday next—to the effect that the examinations of the Rotunda and Coombe Hospitals be recognised as equivalent to the examination of the Central Midwives Board for purposes of registration. We further understand that Mr. J. Gordon, K.C., M.P., will move an amendment in the interests of the Rotunda and Coombe Hospitals, who apparently have at last risen to a sense of the necessity for and importance of defending their charter rights. It is difficult to understand how

any reasonable objection could be offered to the requests of these hospitals. They ask for nothing new, they merely demand that those rights which they have been given by former Parliaments, and those duties which they have so loyally discharged, should be left to them; and that an unjustifiable interference with the position of their trained diplomées should not be permitted, even when presented under the guise of an attempt to improve the training and education of midwifery nurses.

Pathology and Pedigree.

It is somewhat remarkable that although outward physical peculiarities of our ancestors have been oftentimes carefully delineated in family portraits, and not a little of their moral perversions has been handed down by time-protecting tradition, little account has generally been taken of the pathological processes that rung down the curtain on their life's stage. Few people have any accurate information as to the diseases accountable for the death of their grandparents. If the truths of heredity are to be made clear this must be rectified. We venture to think that in every case of obscure disease it would be well that the practitioner should advise not only the holding of a carefully conducted post-mortem examination, but should see that a reasonably detailed report should be prepared and duly signed by those responsible for the investigation. Such a document would prove oftentimes of the greatest service in the unravelling of difficult cases met with in the immediately preceding generations, and would go far to afford reliable data for elucidating the pathology of genealogy.

Cycling Risks in Elderly People.

THE regrettable death of Dr. John Sell Edmund Cotman, of the Minorities, E.C., while on a bicycling trip through Essex, brings home to our readers the fact that cycling is a pastime to be indulged in with prudence and moderation by those who have passed the meridian of life. The unfortunate gentleman, who was well known in London medical circles, was apparently seized with faintness, leading him to get off his machine and lie down by the roadside, where his dead body was subsequently found. Dr. Cotman was upwards of sixty years of age, an age at which it is obviously unadvisable to put any unnecessary strain on the circulation. The country is hilly, and he had to contend with a head wind, and, as the result shows, the exertion was too much for the heart.

The Medical Organisations of Foreign Armies.

THE War Office has issued lately in a handy and cheap form a handbook of the medical organisations (chiefly for war) of foreign armies, which will be of use and value not only to army surgeons, but to any member of the profession or of the public who takes an interest in the vital question of efficient Army Medical Service. The book deals with the organisations of seventeen European countries, and of the

United States, Japan, and Mexico. As a knowledge of these organisations will be required from army surgeons in the future, in examinations for promotion, Lieut.-Colonel F. Howard's "Handbook" will be in considerable request. We also commend it for perusal to the heads of the War Office, as we fancy that it would facilitate the mental assimilation of the fact that the way to obtain an efficient Army Medical Service is not by undermanning and snubbing it.

The Polyclinic Festival Dinner.

THE festival dinner of the Medical Graduates' College and Polyclinic will take place, as announced, tomorrow (Thursday) at the Criterion, the Right Hon. H. H. Asquith, K.C., M.P., in the chair. The list of stewards comprises a large number of distinguished medical men, and the chairman will be supported by an influential Parliamentary contingent, including Sir Weetman Pearson, Bart., M.P., Sir Arthur Trendell, C.M.G., Sir John Cockburn, K.C.M.G., M.D., Sir Alfred C. Lyall, K.C.B., G.C.I.E., Sir Frederick Abel, Bart., K.C.B., Sir Henry Burdett, K.C.B., Sir John Tyler, C.I.E., M.D., Sir William Robinson, G.C.M.G., Sir Chandos Leigh, K.C., C.B., Sir Archibald Geikie, F.R.S., Sir Owen Roberts, M.A., Sir James J. Trevor Lawrence, Bart., The Hon. E. R. Belilios, C.M.G., the Ven. Archdeacon of London, D.D., R. Farquharson, Esq., M.D., M.P., T. P. O'Connor, Esq., M.P., Dr. J. Gutiérrez-Ponce (Columbian Minister), Prof. Clifford Allbutt, F.R.S., and Lieut.-Colonel Babbie, V.C., C.M.G. One great object of the festival is of course to help to place this extremely useful institution on a sound financial basis, and we hope each succeeding effort will mark a step in advance towards the goal.

Small-pox in London.

IN spite of the recrudescence in the number of daily admissions of the last ten days the decrease in the number of cases under treatment is maintained. The total number of cases now in hospital has fallen to less than 1,200, that is to say, some hundreds below the maximum in April last. The Chairman of the Hospitals' Committee has made an interesting statement with regard to the results of the outbreak up to the present. The proper small-pox mortality came out at 16.1 per cent., whereas the actual mortality, including infants, was 16.7 per cent. Speaking generally, about one in six of those attacked had died. On Saturday last a lodger at one of the Rowton Houses applied at the Royal Free Hospital, and was found to be suffering from small-pox.

The Medical Aid Question.

DR. RENDALL, of Great Yarmouth, has withdrawn from an untenable position and has promised the Council not to contract "entangling alliances" in future with societies addicted to canvassing for patients. This prudent conduct on Dr. Rendall's part virtually concludes a campaign which is fraught

with important consequences to the profession. Its significance may be gauged by the fact that no similar charge came before the Council during the recent session, showing that practitioners are alive to the risks which violation of the Council's resolution must entail. The medical profession has given, and is clearly giving, too many practical proofs of its willingness to provide skilled attention to the poor, with or without remuneration, for it to be possible to construe the Council's attitude as a manifestation of "trades unionism," in spite of the petulant utterances of Mr. Chamberlain and others.

PROFESSOR D. J. CUNNINGHAM, M.D., F.R.S., has been appointed an examiner in surgical anatomy and physiology for the Indian Medical Service.

SURGEON-GENERAL PRESTON has resigned his post of P.M.O. of the 3rd Army Corps in Ireland, and has been formally retired under the age limit.

DR. D. C. REES, Senior Government Plague Medical Officer, Cape Colony, has been appointed Medical Inspector on the staff of the Medical Officer of Health for Cape Colony.

MR. HOWARD MARSH is a candidate for re-election on the Council of the Royal College of Surgeons of England; among the other candidates are Mr. Bland Sutton and Mr. J. W. Morgan.

DR. JAMES CRAIG, F.R.C.P.I., has been appointed by the War Office an Examiner in Medicine, and Sir Wm. Thompson, C.B., F.R.C.S., an Examiner in Surgery, on the recommendation of the Advisory Board for Army Medical Services.

MR. ALBAN DORAN, F.R.C.S., has been appointed to deliver the Harveian Lectures for the Harveian Society next November, and has chosen for his subject "Uterine Fibroids Considered from a Clinical and Surgical Standpoint."

THE GENERAL MEDICAL COUNCIL OF EDUCATION AND REGISTRATION.

SUMMER SESSION, 1902.

SIR WM. TURNER, F.R.S., PRESIDENT, IN THE CHAIR.

FIRST DAY.—TUESDAY, MAY 27TH.

THE seventy-fourth session of the Council was opened on Tuesday, May 27th, by the usual Presidential Address.

THE PRESIDENT referred to the progress made with the Midwives Bill and to the fact that, notwithstanding the amendments prepared in consultation with the Midwives Bill Committee of the Council which were moved by Sir John Tuke, the Bill had passed the Grand Committee on Law with but very little change from the form in which it was introduced into the House. No progress, he observed, had been made in Parliament with the Penal and Disciplinary Bill prepared by the Council some time ago, and read for a first time during two Sessions. The Financial Relations Committee, he stated, would during the Session make suggestions to provide for an increase in the income of the Council. The Public Health Committee would again report on the question of the amount of outdoor or practical sanitary work to be done, and on the distribution of the time to be given by candidates for a registrable diploma in Public Health. He regretted to say that the business

of a penal and disciplinary character demanding the attention of the Council was more than usually heavy, chiefly on account of the convictions in the criminal Courts of registered medical practitioners which had been reported to them. Two new cases, in which serious breaches of professional conduct were alleged to have been committed, would also require to be investigated. It was gratifying to find that no registered practitioner was to be charged with the offence of covering, and no new case of a practitioner's associating himself with medical-aid societies which systematically canvassed for patients would have to be considered. A special Indian edition of the Addendum to the British Pharmacopoeia had been prepared and published, and the Government of India had purchased the greater part of the first issue of 4,000 copies. They had been requested by the Privy Council to send a delegate to an International Congress to be held in Brussels on the subject of a proposed International Pharmacopoeia limited to drugs of a drastic nature, and the chairman of the Pharmacopoeia Committee had, at his request, consented to represent the Council. As a result of the extension of Part 2 of the Medical Act (1886) to Italy, a list of foreign practitioners appeared for the first time in the *Medical Register*.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, a vote of thanks was passed to the President for his address, and it was ordered that it be entered on the Minutes.

THE BRITISH MEDICAL ASSOCIATION AND PRELIMINARY EDUCATION.

The British Medical Association having expressed the desire to send a deputation to bring before the Council certain suggestions in respect of the standard of preliminary general education, Sir JOHN TUXE brought up a report by the Executive Committee on the subject. The principal points to which it is desired to direct the attention of the Council are (1) the desirability of making seventeen the earliest age for registration as a medical student, (2) the raising of the standard to a point not lower than that of the senior Oxford and Cambridge local examinations, (3) the introduction of an honours division in which Greek would be a compulsory subject, and (4) the unification of the examination by the appointment of a single examining board.

Mr. G. BROWN having seconded the motion to receive the report, Mr. HORSLEY moved that the deputation be received by the Education Committee on behalf of the Council.

Sir JOHN TUXE urged that if the Council raised the standard the result would be to deplete the profession to the serious detriment of the public, and advocated waiting until they could consider the results of the scheme of secondary education now under discussion.

Mr. HORSLEY's amendment was agreed to, and the Council adjourned early in order that the various committees might meet.

SECOND DAY.—WEDNESDAY, MAY 28TH.

The first business on the agenda was the penal case of Dr. MARCUS ROBERT PHIPPS DORMAN,

who was charged with infamous conduct in a professional respect when attending a married dipsomaniac lady. Under the circumstances, in order to spare the feelings of third parties, the case was heard *in camera*, and on the readmission of strangers the President announced to Dr. Dorman that the Council had found him guilty of the charge, and had directed his name to be erased from the *Register*. The Council then proceeded to the consideration of the case of

JOHN FLANAGAN, L.E.C.P., L.E.C.S. ED.,

of Castlereagh, co. Roscommon, who had been sentenced to a term of imprisonment for having thrown a corrosive fluid on a certain person with intent to inflict grievous bodily injury. An application was read from the solicitor who had defended him at the trial, asking that the consideration of the case might be postponed, an

extensively signed memorial having been sent in on his behalf to the authorities. The Council, however, adopted the usual course of ordering the name to be erased from the *Register*. The next penal case was that of

EDWARD THOMAS FRENCH, F.R.C.S.I.,

who is undergoing a sentence of penal servitude for life for manslaughter. Obviously the defendant was not there to defend himself, and his name was ordered to be removed from the *Register*.

The name of a dentist who had been convicted of bigamy was also ordered to be removed from the *Dentists' Register*, the name of the delinquent being Samuel Marston, of Leicester.

RESULTS OF PROFESSIONAL EXAMINATIONS.

Dr. BALL brought forward a motion to the effect that the Education Committee should be instructed to report as to the desirability of obtaining the following additional information from the various licensing bodies

1. That where credit is allowed for a single subject or groups of subjects only at any examination, the number of students who pass or are rejected in such portion of the examination should be furnished separately from the list of those who pass or are rejected for the entire examination.

2. That in addition to giving a return of the candidates rejected at any examination, the number of such candidates who have been previously rejected upon one or more occasions for the same examination be indicated with the number of such previous rejections in each case.

He pointed out that candidates who were given credit for one part of an examination but were rejected in others appeared as having been both passed and rejected for the same examination. Then, too, the very large proportion of rejections from the Conjoint Boards of Scotland and Ireland (over 50 per cent.) comprised the names of a great number of candidates who had been repeatedly rejected, so that it was difficult to form an estimate from the tables of the proportion of the candidates who had passed the examination on the first trial. With the object of stopping the "chronics" at an early period of their student career he suggested that it might be possible to elaborate a scheme providing that a man rejected at the first trial should be rejected for six months, on a second occasion for twelve months, and on a third unsuccessful trial at the same examination for an even longer period. He thought that this would constitute a great step.

Mr. HORSLEY suggested that the motion should read "That the Registrar be directed to obtain, &c." to which Dr. BALL assented. Mr. HORSLEY added that the matter of the chronic student was one of very great importance to the public, and accordingly he seconded the motion. In the course of the discussion Dr. MACALISTER declared that he was unable to follow the question, and Dr. ATTHILL urged that no candidate's name should be included in the tables unless he had passed the whole examination. Sir CHRISTOPHER NIXON called attention to the importance of securing uniformity among licensing bodies in conducting examinations in regard to groups of subjects.

After further discussion with regard to the wording of Part 2 of the motion, Parts 1 and 2 of the motion were agreed to as they stood originally.

The Council then adjourned.

THIRD DAY.—THURSDAY, MAY 29TH.

PENAL CASE.

The case which first came before the Council was that of an elderly practitioner residing in the suburbs of London who had been convicted of indecent assault at the Central Criminal Court, and had been sentenced to a short term of imprisonment. The case was a very painful one, because the practitioner was a man of high standing and greatly esteemed. It was shown at the trial that he had been suffering from prostatic disease entailing considerable irritation of the genito-urinary

tract, and, as may be inferred from the sentence, the judge took a merciful view in accordance with the medical evidence.

The defendant was present to answer the charge, accompanied by his solicitor. A large number of witnesses to character appeared to give evidence in extenuation, of course not of the offence, but of the conditions under which the offence was committed, including the Member of Parliament for the division, the Vicar of the parish and several eminent physicians who were personally acquainted with the defendant. Evidence was also tendered to the Council bearing on the defendant's state of health. The Council deliberated for a long time *in camera* and on the re-admission of strangers the PRESIDENT announced that in view of the evidence bearing on the physical and mental health of the defendant the Council did not see fit to remove the name from the Register.

The next case was one which has given rise to much discussion in the lay press in respect of the association of registered practitioners with medical aid and similar societies which systematically tout for patients.

DR. ROBERT RENDALL, of YARMOUTH,

the defendant, appeared before the Council in respect of the charge of which he was adjudged guilty last session, viz., "that he had accepted and continued to hold the appointment of medical officer to the Liverpool Victoria Legal Friendly Society at Great Yarmouth, a society which systematically practised canvassing for the purpose of procuring patients, and that he had approved or acquiesced in such canvassing."

At the conclusion of the hearing on the last occasion, Dr. Rendall was directed to appear at the present session in order that he might satisfy the Council as to his conduct in the interval. In the meantime a letter had been received from Dr. Rendall stating that he had sent in his resignation as medical officer, and had entirely severed his connection with the society in question, together with a letter from the secretary of the society acknowledging receipt of the resignation.

Dr. Rendall, in reply to questions, stated that he had no intention of associating himself with any similar society in future.

After deliberation the PRESIDENT announced to him that under the circumstances the Council had resolved to take no further action in the matter.

REGISTERED AFTER MANY DAYS.

The Council, on the recommendation of the English Branch Council, authorised the admission to the Register of the name of Mr. Abiathar Wall, L.S.A. Lond., L.R.C.P.S. Ed., M.R.C.S.E. 1872, who had neglected to effect his registration before the appointed day (June 30th, 1887).

Another penal case then came up, the defendant being

MR. WILLIAM PARK, M.B., M.S. GLASG.,

of Gartlea House, Airdrie, who was charged with having seduced and eloped with a married woman under his care at a hydropathic establishment at Limpley Stoke, near Bath. The husband attended in support of his complaint with counsel and solicitor.

The defendant did not appear, but was represented by counsel, who applied for a postponement of the hearing on the ground that his client was absent in virtue of his engagement as medical officer to a steamship company. Mr. Park's solicitor admitted having received an intimation from the Council's solicitor that if Mr. Park did not attend the inquiry it would be at his own risk. The postponement was opposed on behalf of the complainant, and the Council proceeded with the case, which was heard *in camera*. Ultimately Mr. Park was adjudged guilty of "infamous conduct in a professional respect," and his name was directed to be removed from the Register.

FOURTH DAY.—FRIDAY, MAY 30TH.

The various committees having been re-elected, the Council proceeded to discuss the

REPORT OF THE FINANCIAL RELATIONS COMMITTEE.

In this report the unsatisfactory financial situation

of the Council is set forth in plain figures, the annual deficit being £1,200, and the Committee express the opinion that the deficiency cannot be met by such economies as have been proposed by various Finance Committees in the past. It states that to readjust permanently the relations between the Council and the Branch Councils will entail certain amendments of the Medical Acts 1858 and 1886. Going into the financial history of the Council, the report states that upwards of £35,000 was received from the original £2 registration fees, and the assets of the Council at one time with interest amounted to £75,485, but have since fallen to £41,500. It follows that the current £5 registration fees have failed to meet the expenditure and the Branch Councils have only the accumulations of past fees to fall back upon, that of the Irish Branch Council being long since exhausted. The problems before the Council are (1) to provide sufficient revenue for the execution of its duties, and (2) to constitute a central financial administration.

Revenue.—There are three courses open to the Council:—To raise the initial registration fee; to substitute a small annual registration fee for the initial payment; or to institute a students' registration fee. The Committee favour the idea of imposing a £1 students' registration fee and are not averse to raising the initial registration fee for practitioners to £7 instead of £5. Among the amendments to the Medical Acts suggested with financial equilibrium in view are the virtual abolition of the Branch Councils with their registrars and officers, the payment of all fees, &c., into a central treasury, an increase of the initial registration fee to £7, and the payment of the expenses of direct representatives as part of the expenses of the General Council instead of by the particular Branch Council. Mr. HORSLEY appends a note to the effect that in his opinion the difficulties can only be overcome by the institution of a small annual payment, and by extensive reform of the Medical Acts, while Dr. HERON WATSON urges curtailment of expenditure on the ground that the imposition of an annual charge would render the Council unpopular with the profession, and, finally, a lengthening of the hours of work with a reduction in the length of speeches, and, if necessary, the withdrawal of the allowances at present made in respect of travelling and hotel expenses. He anticipates strenuous resistance in Parliament to any proposal to impose such a charge. In these views Dr. BRUCE concurred.

Taking the recommendations *seriatim*, Dr. ATTHILL moved that the Council approve the principle of a registration tax of £1 on students. An amendment by Dr. WATSON inviting the Council to postpone committing itself until the committee had inquired what could be done in the direction of the curtailment of expenses was negatived, the names being taken down so that the profession might see how the cat jumps. An amendment was moved by Dr. NORMAN MOORE on the same lines. He argued that since the Council has no power to compel students to register, a registration fee would necessarily prove an uncertain source of income. Before imposing a registration fee on students they ought to be able to point to some advantage in exchange therefor, either to the student or to the public, and in neither respect was he able to see any advantage. He urged that it was a most undesirable thing to turn a voluntary into a compulsory registration as a means of increasing the Council's income. He saw, however, no difficulty in the way of increasing the registration fee for practitioners, but before they went to Parliament they must make it clear that they were going to do more useful work, and that they were as economical as possible. He suggested that the proposal would lead to criticism of their usefulness, and would give rise to the question whether it was "worth while to pay for more of this sort of thing."

Dr. ATTHILL then proposed the increase of the initial registration fee to £7, to which Mr. JACKSON, seconded by Mr. HORSLEY, moved as an amendment that an annual fee of ten shillings be substituted for the initial registration fee of £5, such annual fee to be paid for ten years by those who had already paid the £5 registration fee. This was negatived and again the names were taken down. They were as follows:

Against, 22.—Dr. MacAlister, Mr. Bryant, Dr. Norman Moore, Dr. Payne, Mr. Tomes, Dr. Pye-Smith, Dr. Atthill, Dr. McVail, Dr. Heron Watson, Mr. Ball, Dr. Mackay, Dr. Finlay, Sir John Williams, Sir C. Nixon, Dr. Bennett, Sir G. Philipson, Dr. Windle, Sir Hector Cameron, Sir William Thomson, Dr. Bruce, Dr. Little, Sir Hugh Beevor.

For (3).—Mr. Brown, Mr. Jackson, Mr. Horsley.

Did Not Vote (3).—The President, Sir William Gairdner, Mr. Tichborne.

Absent.—Mr. Power and Sir John Tuke.

Sir WILLIAM THOMSON, seconded by Dr. WINDLE, then moved an amendment that the registration fee be raised "from £5 to a sum not exceeding £10," and this was carried and subsequently confirmed as a substantive motion.

The adoption of the paragraph advising that the financial administration of the funds should be remodelled so far as the mutual relations of the Council and its Branch Councils are concerned was agreed to on the motion of Mr. HORSLEY. It was then proposed by Mr. HORSLEY that the Financial Relations Committee should be reappointed with instructions to draft a Medical Acts' Amendment Bill carrying out the principles of financial reform approved by the Council, but the hour for adjournment having been reached, the decision was postponed.

FIFTH DAY.—SATURDAY, MAY 31ST.

Resuming the discussion on the proposed reappointment of the Financial Relations Committee, Dr. LITTLE moved an amendment leaving it to the President to make provisional arrangements for carrying on the business of the Council with a view to economy and dispensing with any Standing Orders to the contrary. This unbusinesslike proposal was promptly negatived. At the suggestion of Dr. MACKAY a paragraph was added—by consent of the mover and seconder—to the original motion, instructing the committee to consider what economies in the expenditure of the Council it might be possible to effect.

A long discussion followed, each speaker having his special views as to the direction in which economies might, and therefore should, be effected. To Dr. PYE-SMITH belongs the credit of having put his finger on the philosopher's stone of Council finance, viz., a reduction in the number of members of the Council. Such reduction in addition to reducing the expenditure in fees by, shall we say, one-half or three-quarters, according to the thoroughness of the reform, would add materially to the efficiency of the Council as an administrative machine. Ultimately it became necessary to put a term to the eloquence of members, so on the motion of Dr. ATTHILL, the closure was applied, and the original motion as modified was passed by 20 votes to 4; six members not voting, an abstention from duty which ought to be punished by a standing order. The Financial Relations Committee is therefore entrusted with the task of preparing a draft Medical Acts' Amendment Bill, and of deciding what economies are practicable in the expenditure of the Council, the report to be presented at the next meeting of the Council.

REPORT OF FINANCE COMMITTEE.

The report of the Finance Committee on income and expenditure for 1901 was received. According to this report the income of the General and Branch Councils for the twelve months ending December 31st last was £8,557, while the expenditure for the same period was £10,065, leaving a deficit on the year's working of £1,508.

Obviously something requires to be done at once in order to check the annually increasing deficit, and accordingly Mr. TOMES, seconded by Dr. ATTHILL, moved that the payments to the sinking-fund be discontinued. Dr. ATTHILL argued that it was the best way of economising, and added that the necessary steps should be taken to obtain the refund of the sums already paid, which amounted to £215 per annum.—Mr. BRYANT deprecated taking such a step as this, thus undoing what was done two years ago.—Sir WILLIAM THOMSON

agreed with Mr. Bryant, inasmuch as the Sinking Fund was established on expert advice, but since then expert advice had condemned it. He asked why the fund should be continued for the benefit of future generations. By discontinuing the payment, according to Dr. MACALISTER, they assumed they were at liberty to take the funds of any branch council, because the fund was started in the first place to enable the Council to pay back the debt to the English Branch Council. The motion that the payment of the Sinking Fund be discontinued, and that the necessary steps be taken in accordance with the alliance of the Assurance Company for the refunding of the sums paid, was put to the vote and carried.

PAYMENT OF VISITORS.

It was agreed that, subject to the approval of the Privy Council, the remuneration of the visitors of the primary examination of the Examining Board of the Royal Colleges in England be at the rate of £5 5s. a day, with travelling and hotel expenses. One of the two persons appointed to visit is to be a member of the Council, the other an expert.

REPORT OF PERSONATION COMMITTEE.

The Council then resumed the discussion on the report of the Personation Committee left over from last session, and after adopting several of the recommendations adjourned until Monday.

SIXTH DAY.—MONDAY, JUNE 2ND.

The PRESIDENT recalled to the Council when they met on Monday that the last meeting terminated in the middle of the consideration of the report of the Committee on the Prevention of Personation. There were other matters on the programme of more material importance, however, which he thought should be taken first, while the members were fresh, and he called on Mr. BRYANT to bring forward the reports of the Examination Committee on the inspection of the final examinations of the Scottish Conjoint Board, and of the Irish University. With regard to the former Mr. HORSLEY took exception to the use by the visitor of the "well-known word 'sufficient,'" which, he said, the Council only were entitled to use, and wanted to know precisely what was in Dr. Payne's mind when he used it. It was explained that "sufficient" was a Parliamentary term indicated by the Medical Act of 1836. Sir WM. THOMPSON thought that a much more important matter was the absence referred to in the report of an examination in operative surgery. He greatly regretted that such was the case, and though he knew that in some countries and in former times people were very sensitive about handing over their dead for anatomical study, he thought that in these days it was really expense rather than sentiment which stood in the way. The PRESIDENT, however, speaking with authority, said that that was not so. Both reports were received, entered, and adopted without opposition.

The report of the Students' Registration Committee was soon adopted, but had it come up earlier it is possible that well-worn dissensions would have revived, as controversial matter was touched upon. An application, to be registered and antedated, under exceptional circumstances, had come on behalf of T. T. O'Farrell, who had passed the Preliminary Examination of the Irish Conjoint Board, and had begun medical study at Stonyhurst College in September, 1901, requesting that he might be allowed to register and antedate to the time of commencement of medical study. The Committee resolved:—"That Mr. O'Farrell be informed that Stonyhurst College has not been approved by the Council as a place for the commencement of medical study."

Dr. NORMAN MOORE was up in arms, protesting that the Council would put itself in a false position if it did not at any rate inquire into and investigate the training given at Stonyhurst. Stonyhurst was not a grammar school; it was on quite a different footing. He proposed, and Sir C. NIXON seconded, that the resolution of the Committee be amended as follows:—"That Mr. O'Farrell be informed that the Council will make inquiries, and if it should find that Stonyhurst provides

laboratories, appliances, and teachers necessary for the efficient commencement of medical study, his application will be acceded to." Sir HUGH BEEVOY said that Stonyhurst was a famous school, but not a scientific institution. Dr. WINDLE, speaking as one familiar with Stonyhurst, said that the laboratories were excellent for a school, but with every respect for the school, he should vote against the amendment on the ground that it was an attempt by a side wind to get the Council to rescind a resolution previously arrived at, and the issue of which must be faced squarely and plainly. The amendment was lost and the report was adopted.

A long discussion on the report of the Public Health Committee occupied rather more than the remainder of the afternoon—the Council not rising till a quarter of an hour after closing time. The chief dissension arose over a point which was settled two years ago, but which some of the members had not ceased regretting. The candidate for Public Health Diploma can now qualify after a nine months' course, and Sir J. TUCKER lamented that year by year the requirements were whittled down. Dr. McVAIL persisted that a nine months' course had been allowed only for army men, and that only because of the difficulty in getting leave of absence. The feeling was so strong that the Council thought if the concession was not made the Government would set aside the Council's qualification and set up one of their own. It was shown, however, that the nine months' curriculum had been adopted, and the question that afternoon was how the time should be disposed of to the most advantage. An addition to the regulations was finally made as follows, the wording being carefully edited so that there would be no possibility of the candidate telescoping, as Dr. MACALISTER pointed out, his nine months into six months, which shall be distinct and separate from the laboratory instruction required in Rule 3:—

The period may be reduced to three months in the case of any candidate who produces evidence that, after obtaining a registrable qualification, he has during three months attended a course or courses of instruction in sanitary law, sanitary engineering, vital statistics, or other subjects bearing on Public Health administration, given by a teacher in the Department of Public Health of a recognised medical school.

The exemption proposed in the case of a practitioner who had acted for six months as a medical officer of health, or who belonged to H.M. service in the Navy or Army or the Colonies, was withdrawn at the instigation of Dr. McVAIL. The regulation that candidates after obtaining a registrable qualification must attend the practice of a hospital for infectious diseases, at which opportunities were afforded for the study of methods of administration, produced considerable antagonism. Dr. BENNETT said that in Ireland such a course would be impossible, and moved that the paragraph end at "diseases," and Dr. NORMAN MOORE said that in London it would be extremely difficult and practically unworkable. Dr. MACALISTER asked what would be the use of sending a qualified man back to study infectious diseases; the whole point lay in the conclusion of the sentence, which had been put in after great consideration. Why should they lower the standard because of a temporary difficulty? An officer of public health must have practical administrative experience. Dr. BRUCE appreciated the difficulty, and was willing to withdraw the line, but Dr. McVAIL declared that that was a point on which the late Sir E. Thorne insisted strongly, that a medical officer without administrative knowledge was perfectly useless, and no diploma should be granted which did not imply that knowledge. If a student could not get it in London he must get it elsewhere. Mr. BROWN also urged the Council strongly not to tamper with the clause. In the end, therefore, it remained.

Then, after the termination of the usual formal business, the session was brought to an end.

The Oxygen Cylinder Again.

THE medical officer to the ss. *Ville d'Alger*, while engaged in administering oxygen inhalations to sea-sick passengers one day last week, was injured by the bursting of the brass (?) cylinder, and died a few hours later.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

REPORTING ON PATHOLOGICAL PRODUCTS IN EDINBURGH.

IN view of the decision of the Town Council to transfer this work from the laboratory of the Royal College of Physicians to the Usher Institute of Public Health, the College has intimated to the medical men of the city that it will revert to the old system of reporting on specimens sent to it. This means that in future the laboratory will accept specimens directly, instead of through the Public Health Department, and will examine them gratuitously for members of the profession.

THE NEW CHAIR OF PUBLIC HEALTH IN EDINBURGH UNIVERSITY.

IN his inaugural address in connection with this new chair, which was founded by Sir John Usher and the late Mr. A. L. Bruce, Professor Hunter Stewart gave a brief sketch of the development of preventive medicine, and showed what part the Edinburgh School has played therein. Two hundred years ago medical science was directed entirely to the cure of disease. It had shared in the great revival consequent on the appearance of the *Novum Organum*, so soon to be followed by the works of Harvey, of Boyle, and of Sydenham, but the great impulse which the study of medicine had received from Sydenham was entirely on its curative side. It appeared that the prevention of epidemics was excluded by Sydenham's views, since the disease would continue so long as the constitution of the atmosphere remained unchanged, and the latter was beyond human control. The next great agency in preparing the way for preventive medicine was the teaching of Boerhaave, which exerted a great influence during the first half of the eighteenth century and beyond it. Boerhaave was a pupil of Pitcairn, one of the first professors of medicine in Edinburgh, when that distinguished man was a professor in Leyden. Like Boyle, Boerhaave restricted the term fermentation to a specific process, and defined it as a change which could be set up on some vegetable substances and resulted in the formation of what is now known as carbonic acid, and wine or vinegar. Richard Mead, another pupil of Pitcairn, in his essay on poisons distinguished between such poisons as carbonic acid and laurel water, whose action is immediate, and those like hydrophobia, whose action is latent or delayed. The existence of a latent period in certain diseases was further demonstrated, when inoculation for small-pox was introduced in 1722, as the time that elapsed between the inoculation and the appearance of the constitutional symptoms could be noted. Mead pointed out that the Chinese inoculated on the inside of the nostrils, and that this was followed by a severe attack of the disease. This point he verified in the case of a condemned criminal, who volunteered for the purpose, and noted that not only was the disease more severe, but also appeared earlier than in others whom he inoculated on a skin surface. At the present day inoculation of the bacillus of plague inside the nostril of an animal was a means of exalting the virulence of the organism. Briefly stated, at the middle of the eighteenth century Sydenham's doctrine of epidemic constitution continued to oppose preventive measures. The conception of contagion was still vague—by some it was considered as self-propagative, having the properties of yeast, while the greater number looked upon it as a volatile body, the result of putrefaction. The nineteenth century opened with the introduction of vaccination, and in the latter half of which, especially, new lines of research were opened up and a great advance in preventive medicine ensued, but it was fitting to recall the great work done in the eighteenth century by those who laid the foundation of this branch of medical science.

THE NEW USHER INSTITUTE OF PUBLIC HEALTH

will be formally declared open within a few days, though it is doubtful whether Mr. A. J. Balfour, the Chancellor of the University, will, as was expected, be able to attend in person. The origin of the Usher Institute has been

already referred to, the stipulation made by the donor after whom the building is named being that the University should find a site. As the space available near the present medical buildings would have so cramped the building that a proper light could not have been obtained, a site further afield had to be sought, and was found about half a mile from the University, in the heart of the students' quarter. In external appearance the building somewhat resembles the new University buildings, and it consists of three storeys. On the ground floor there is to the east of the entrance hall a lofty museum, in which educational specimens are to be shown, including tubes of cultures, specimens illustrating diseases of animals communicable to man, models of filter-beds, examples of the means adopted for the protection of workmen engaged in noxious trades, disinfecting apparatus, &c. Adjoining the museum is a research room fitted up in the most modern fashion; at the table upon which research work is to be done there is a ventilating shaft with continuous down draught, and a similar system is applied to all tables in the laboratories and other research rooms, in addition to the usual fume chambers. On this floor there is also a gas analysis room and a photographic room. In the west wing, upon the ground floor, are the three rooms which are to be devoted to the city bacteriological work, one being an office, and the other two laboratories. On the first floor, in the east wing, above the museum, is the chemical room, accommodating eighteen workers, each of whom has a fully equipped table supplied with ordinary water, pressure water, pressure air, steam, gas, electricity, and special ventilating shaft. Steady pressure of water is automatically secured, and great care has been taken to avoid undue waste. The lecture theatre will accommodate 274 students, and is lighted both from the sides and top. The room can be darkened from the lecturer's desk, when lantern demonstrations are to be given. There are many other novel provisions and accessories which will render this institute the most perfect of its class, and cause it to be followed as a model for some time to come.

PUBLIC HEALTH DEGREES.

The Glasgow University has instituted two degrees in Public Health, viz., B.Sc. (Public Health) and D.Sc. (Public Health), an example which is certain to be followed by many other degree-conferring bodies. These, not being qualifying diplomas, do not come within the purview of the General Medical Council, so that the standard of knowledge exacted of postulants will be determined solely by the University authorities.

Belfast.

[FROM OUR OWN CORRESPONDENT.]

[We are not responsible for opinions expressed by our local correspondents.]

SWORN INQUIRY INTO THE EXCESSIVE EXPENDITURE ON MEDICINES AND APPLIANCES.

THE sworn inquiry at the Belfast Union Workhouse into the expenditure on medicines and medical and surgical appliances, to which reference was made in this column last week, has been proceeding daily since, and has been the means of bringing to light some very curious facts. The apothecary, in examination, admitted that the use of fifty-three reams of paper, at a gross cost of £22 18s. during the six months was a pretty big item. The nurses got the paper for various purposes, and he drew their attention to the extravagant use of it. The use of 86 cwt. of linseed meal in six months at 24s. a cwt. was also large; no check was kept on its consumption. He did not use more than two shillings' worth of sacchara purificata in the twelve months; he had no reason to dispute the item that 26 cwt. of this sugar had been consumed in the infirmary, and 4 cwt. in the hospital in six months, at a gross cost of over £50. He accepted the figures relating to safety pins—that 178 gross had been used in six months at a cost of over £45; 157 pairs of scissors and 21 dozen of thermometers.

Dr. John M'Leish, visiting medical officer, was examined regarding the use of various drugs. He said he was largely responsible for the use of sulphate of potash, which he used in the proportion of $\frac{1}{2}$ lb. to 30 gallons of water for cases of itch, but each bath so made would suffice for five patients. Questioned as to the use of kali water, he said it did not strike him as a luxurious drink, and he did not know of any cheap substitute. He shared with Drs. Hall and Lyness the responsibility of ordering lemons, of which twenty-two cases at a gross cost of 10s. per case were used in the infirmary; he thought this amount could well be reduced.

Benjamin Clarke, of the contracting firm of druggists, admitted having altered without authority the order for rubber air cushions; he supplied the red rubber because the winsey had been returned on several occasions. He had supplied 243 dozen syphons of kali water at six shillings per dozen, making £74 8s. That was the price he contracted for; he did not know the retail price. The fact that the Master had obtained a quotation from a Belfast firm, at the Inspector's request, for refilling syphons of kali at 3s. 8d. per dozen did not concern him in the least. He had nothing in writing to show to justify him in overriding the contract for a number of spittoons at 3s. 6d. per dozen, and not 18s. per dozen as supplied.

Dr. William Burns, senior resident medical officer, said he had held that post for ten months, and had previously held a junior post for six years. He said there was no individual exercising authoritative control over the expenditure in the Infirmary; he thought there was no satisfactory check on waste at the present time. Lint and cotton wool were most affected by the waste. He thought the item for lint, 2,032 lbs., was excessive.

Dr. Nicholas M'Donnell (chairman of the Infirmary Committee) considered that there were several articles on the official list priced far too high, and that if the guardians were free to contract for these they would get them at a lower price than the Local Government Board fixed.

Miss M. A. Carlile, workhouse nurse and superintendent of the infirmary, stated that she had eighty-six nurses under her charge, including probationers. Speaking generally, she could not say that there was any wilful waste, but she would not say to the contrary.

Mr. J. C. Neeson, Clerk to the Board of Guardians, explained various matters concerning the contract for medicines, &c., and how they were made. He said that carbolicene was tendered for at 6s. per gallon, and it could be obtained (according to evidence admitted at that inquiry) at 2s. 6d. per gallon in the quantities used, so that on 526 gallons used the Guardians lost £92 1s. Phenyl was tendered for at 5s. per quart, and could be obtained at 3s. 9d. per gallon, so that the Guardians lost on that item £28 8s. 9d. Similarly on the kali water they lost £3 18s. 8d., or a total of £129 8s. 5d. on these three items alone, in six months.

Dr. Robb, visiting medical officer to the Fever Hospital, gave some particulars as to drugs used. He explained that medicines ordered in small doses, such as opium, were given in tabloid form, and that if they were ordered as powders, one apothecary could not do the work of the establishment.

The inquiry is now closed, and the decision rests with the Local Government Board.

Measles in Plymouth.

A WIDESPREAD epidemic of measles is raging at Plymouth, the number of cases under treatment being upwards of a thousand.

Muzzling Orders.

THE Board of Agriculture has issued an order applying the muzzling regulations to certain parts of Devonshire and Cornwall.

Tuberculin Test for Cattle.

THE Canadian Government have sent Mr. A. G. Hopkins, Veterinary Quarantine Officer for Canada, to this country to apply the tuberculin test to all cattle over six months old intended for export, for breeding purposes, from the United Kingdom to Canada.

ROYAL COLLEGE OF SURGEONS, IRELAND.

At a meeting of the Fellows held on Monday, June 2nd, for the election of president, vice-president, honorary secretary, and council for the ensuing year, the following were elected:—President: Lambert H. Ormsby. Vice-President: Arthur Chance. Honorary Secretary: Sir Charles Cameron. Council: Sir Philip Smyly, H. R. Swanzy, E. H. Bennett, Sir Charles Cameron, Austin Maldon, J. B. Story, Sir W. Thomson, C. B. Ball, T. Myles, J. Lentaigue, R. D. Purefoy, H. G. Sherlock, R. B. McCarsland, R. H. Woods, T. Donnelly, F. T. P. Newell, J. D. McFeely, W. Taylor, and H. W. Oulton.

DR. WALDO, Coroner for the City of London, proved too rapid in his movements for a burglar who entered his house on Sunday last. The prisoner will not again have the opportunity of running a race with the Coroner for some time to come.

On Monday last his Majesty the King invested Lieut.-Colonel Arthur P. O'Connor, of the Royal Army Medical Corps, with the order of the Bath (C.B.), and Surgeon-Captain A. Martin Leake with the Victoria Cross, for distinguished services in South Africa.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE DESTRUCTION OF PLAGUE-INFECTED RATS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I note in your issue of the 21st inst. reference made to the experiments carried on by Mr. Langlois and myself with the object of ascertaining the best methods of disinfecting the holds of ships in cases of suspected plague infection.

There are one or two slight inaccuracies in your notice, which I should feel obliged by your correcting. We found that rats succumbed to a prolonged exposure in an atmosphere of CO_2 , although they revived in many cases when restored to the fresh air, but that fleas showed little symptoms of being affected by CO_2 , and that this gas cannot be looked upon as trustworthy for destroying insect life. We do not believe that by burning sulphur in the holds of vessels an efficient disinfection by sulphurous acid gas can be obtained, and we think that the only certain way is to produce this gas outside the compartments to be treated, into which it is to be introduced under sufficient pressure to ensure its thorough diffusion.

In this connection I would refer you to an article by Mr. Langlois and myself published in the *Revue d'Hygiène* of the 20th inst., in which the whole subject is more fully treated than in the publication that you refer to. As far as we know, Mr. Chantemesse never carried on any experiments on this subject in New Orleans, but the results you state as to the effect of a 17 per cent. SO_2 gas were obtained in repeated experiments here in Paris.

I am, Sir, yours truly,

A. LOIS, M.D.

45, Rue des Acacias, Paris, May 28th, 1902.

Failure to Notify.

DR. DAVID GWEN KENNEDY, of Jamaica Road, Bermondsey, was fined £2 with £5 ss. costs for having failed to notify a case of chicken-pox. It appears to have been merely an oversight, and this being the case the penalty was needlessly heavy.

An Epidemic at Lincoln.

A MYSTERIOUS epidemic of a septic character has broken out at Lincoln. It has been traced to the milk from a particular dairy, but its nature remains obscure. There have been some eighty cases, with several deaths.

Literature.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. (a)

THE special feature of this number of the Reports is the table of X-ray photographs taken during the year 1900; they number 184, of which thirty-eight were taken of the leg and foot. Of nine photographs of the kidney for calculi not one was successful. From the statistics of anaesthetics we learn that chloroform alone was administered 2,561 times, ether alone 43 times, and the A.C.E. mixture but once. Of the contributions the most interesting was Mr. H. J. Butlin's, "On the Results of Operation for Primary Cancer of the Breast," and "Surgical Emergencies." Sir D. Duckworth's "The Pathology of Chorea" is a masterly, but not altogether successful attempt to solve a difficult problem.

ANATOMIE GENERALE. (b)

THE second part of this physiological and medical anatomy completes the work. The whole work may be regarded not only as a book on anatomy from a physiological and medical point of view, but also as a deep philosophical treatise. The second part deals with systems special to certain apparatus. The reader is taken through the osseous, the medullary, the cartilaginous, the fibrous, the fibro-cartilaginous, the muscular, the mucous, the serous, the synovial, the glandular, the dermoid, the epidermoid, and the fibrous systems, all being severally considered from the mechanical, the physiological, the physical, the vital, the organic, the inorganic, the developmental, and the functional points of view; the whole being an interesting study for the philosophical mind of any philosophical medical man or student of physiology, who will be well repaid for the perusal of the scholarly text.

Obituary.

DR. WM. JEPHSON WEEDON.

It is with sincere regret that we announce the death of Dr. W. J. Weedon, of Merrion Gorey, co. Wexford, at the comparatively early age of 57 years, which took place in Stevens' Hospital, Dublin. Some nine or ten months ago Dr. Weedon noticed the onset of jaundice, which did not yield to the ordinary remedies, and as it continued to increase in severity he came to Dublin, placing himself in the hands of his friend, Mr. Swane. Dr. Weedon was the youngest son of the late Canon Percival Banks Weedon, M.A., Rector of Fethard, and a Canon of Ferns Cathedral. He qualified in 1868, and soon afterwards practised in England, and subsequently at Bathville, co. Carlow. On the death of his brother he was appointed Medical Officer of the Gorey Dispensary District, an appointment which he vacated seven years since, on being appointed Medical Officer to the Workhouse, Gorey. His death is mourned throughout the district, where for many years his skill, patience, and friendship had been often tested, and ever bore the trial and confirmed the faith and devotion of his large circle of friends.

Medical News.

The Vacant Coronerships.

THE death of Mr. Braxton Hicks, Coroner for the South Western District of the County of London, and for the Kingston Division of the County of Surrey, will probably open the way to a re-arrangement of districts. It is stated that the plan most in favour is to divide the south-western district, apportioning each division to that of an existing coroner. In such case, of course, no vacancy will be declared, but in the meantime, various candidates are already in the field, among whom are Dr. Ambrose (Coroner for Essex), Dr. Bateman (Deputy-Coroner for St. Albans District), Dr. Beardmore,

(a) "Saint Bartholomew's Hospital Reports." Edited by Norman Moore, M.D., and Henry Power, F.R.C.S. Vol. xxvii. London: Smith, Elder and Co. 1902.

(b) "Anatomie Générale Appliquée de la Physiologie et de la Médecine." Par Xavier Bichat. Deuxième partie. Pp. 573. Paris: G. Steinheil.

Dr. Bryce, Dr. Freyberger, Dr. Major Greenwood, Dr. Guthrie, Dr. Houchin (Deputy-Coroner for East London), Dr. Bernard O'Connor, Dr. Oddie, Dr. Oswald (Deputy-Coroner West London and the Kingston District of Surrey), Dr. W. R. Smith (late Medical Officer of the London School Board), and Dr. M. H. Taylor (Deputy-Coroner for the South-Western District). Mr. Hodgkinson, solicitor, and now Coroner for the Eastern District of Middlesex, and Mr. Troutbeck, Coroner for Westminster, are also candidates.

Medico-Psychological Association.

At a meeting of the Medico-Psychological Association of Great Britain and Ireland, held on Friday, May 23rd, in the Royal College of Physicians, Dublin, Dr. Dawson, Farnham House, Finglas, Co. Dublin, was unanimously elected hon. secretary of the division for Ireland, vice Dr. Arthur Finegan, R.M.S., resigned. Dr. Finegan was, at the same meeting, unanimously elected to represent Ireland on the Council of the Association.

A Nurse's Action for Damages.

A CLAIM for damages brought against the *Sun* newspaper by the superintendent nurse of the Lambeth Workhouse was tried in the High Court last week, and the plaintiff was awarded £600. The circumstances were somewhat peculiar. It seems that certain allegations had been made against the plaintiff by a patient, and these were brought before the Guardians. The alleged libel lay in the fact that the report published by the *Sun*, under sensational headlines, only comprised the details of the charges, and omitted to add that the Guardians virtually dismissed the matter, thereby allowing it to be understood that the plaintiff had not made any answer to the charges. Perhaps this sharp lesson will render certain editors a trifle more careful before they attempt to obtain a *succès de scandale* at the expense of officers of hospitals and similar institutions.

Pathological Frivolities.

THE President of the Pathological and Harveian Societies (Mr. Watson Cheyne) and Mrs. Watson Cheyne held a reception on Tuesday of last week at the Royal Botanical Gardens, Regent's Park, which was attended by nearly 2,000 medical and other guests. The gardens were tastefully and lavishly illuminated, and in spite of the rather unsettled weather, the guests were enabled to enjoy an *al fresco* entertainment, enlivened by the strains of the London Heavy Cavalry Band (under the conductorship of Mr. A. E. Davies), who played a choice and varied selection throughout the evening. The more energetic were afforded facilities for exercising the "light fantastic toe," of which they availed themselves to the utmost within the limits assigned by space to their gyrations. It is to be hoped that the sick and the ailing did not suffer unduly in consequence of the absence from duty of a very large proportion of the consultants and practitioners of the metropolis. "Our hosts" may be congratulated on having provided a very charming evening.

St. Thomas's Hospital.—House Appointments.

THE following gentlemen have been selected as House Officers from yesterday (June 3rd, 1902):—

House Physicians.—T. B. Henderson, M.A., M.B., B.Ch., Oxon (Extension); H. S. Stannus, L.R.C.P., M.R.C.S. (Extension); H. W. Sinclair, M.B.Lond., L.R.C.P., M.R.C.S.; K. E. Crompton, B.A., M.B., B.C. Cantab.

Assistant House Physicians.—A. D. Hamilton, M.B. Lond., L.R.C.P., M.R.C.S.; C. H. Sedgwick, B.A., B.C. Cantab.

House Surgeons.—G. A. C. Shipman, M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S.; B. S. Jones, L.R.C.P., M.R.C.S.; T. W. H. Downes, L.R.C.P., M.R.C.S.; F. J. Child, M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S. (Extension).

Assistant House Surgeons.—J. Coates, L.R.C.P.,

M.R.C.S., A. C. Hudson, M.A., M.B., B.C. Cantab.; H. Spurrier, B.A. Cantab., L.R.C.P., M.R.C.S. (Extension).

Obstetric House Physicians.—(Senior) T. D. Miller, L.R.C.P., M.R.C.S.; (Junior) E. E. Roberts, M.B., B.Sc. Lond.

Clinical Assistants in the Special Department for Diseases of the Throat.—Z. Mennell, M.B.Lond., L.R.C.P., M.R.C.S. (Extension); B. E. Sansom, L.R.C.P., M.R.C.S., L.S.A. (Extension). Skin: H. A. Easton, L.R.C.P., M.R.C.S. (Extension). Ear: H. S. D. Browne, B.A. Cantab., L.R.C.P., M.R.C.S. (Extension).

Death from Hydrophobia.

MR. THOMAS BOWEN, residing at Garnent, Llanelly, died last week from hydrophobia. He was bitten in the hand by a fox terrier in August, 1900, and underwent treatment at the Pasteur Institute, at Paris. A lad who was bitten at the same time, and also underwent the treatment, remains in good health.

Society for the Study of Disease in Children.

WE are asked to announce that the provincial meeting of the Society for the Study of Disease in Children will be held at the Pendlebury Children's Hospital, Manchester, this year on Friday, June 20th, at 4 p.m., and so far the following communications have been promised:—"Some Remarks on Heart Disease in Children," by Dr. A. E. Sansom; "On Tendon Grafting, with Cases," by Mr. W. P. Montgomery; "On Splenic Enlargements, with Some Observations on the Blood," by Dr. Henry Ashby and Dr. George Carpenter; "Atresia of the Cornis Pulmonalis with Patent Septum Ventriculorum," by Dr. E. Cautley; "The Surgical Treatment of a Case of Infantile Paralysis of the Lower Extremity," by Mr. C. M. Gwynne (Sheffield); "Fleeting Amaurosis in Children Presenting Symptoms of Meningitis," by Mr. Sydney Stephenson. At the conclusion of the meeting the members and their friends will dine at the Queen's Hotel. The following day an excursion into Derbyshire has been so arranged that members will be able to return to town the same night, and those who intend to be present are requested to communicate with Dr. George Carpenter, Welbeck Street, W., as soon as possible. The annual general meeting of the Society will be held at the Hotel Cecil, July 16th, at 6.45 p.m., and will be followed by dinner at 7.30 p.m.

Pass Lists.

University of London.

THE following candidates passed the M.B. Examination during May; names arranged in alphabetical order:—

FIRST DIVISION.

Fedden, Walter Fedde | Harvey, Percival George

SECOND DIVISION.

Addison, Oswald Lacy	Haslam, Arthur Charles
Atkinson, Fred. Cecil E.	Hodgson, Stanley
Aubrey, Thomas	Houghton, Norris N. A.
Bain, Edward Walter	Howell, Francis Musgrave
Barber, Hugh	Jones, William Henry
Cambridge, Percy John	Longmead, Fred. Samuel
Chennells, Ernest Philip	Page, William Sydney
Clarke, Edward Murray	Phillips, Rees
Colwell, Hector Alfred	Pollard, Herbert Dean
Dunnett, Agnes Emma	Price, David Thomas
Evans, Erie	Rees, Morgan James
Evans, John	Savill, Philip
Fisher, Edward Fow	Stuart, Emily Gertrude
Forayth, David	Taylor, George Orissa
French, John Gay	Ward, Vere Godsalve
Gibson, Fred. Goulburn	Wellburn, Lucy
Hamilton, Arch. Douglas	

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on *one side of the paper only*, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

DIABETIC COOKERY.

A CORRESPONDENT writes in reply to the query of "Anchettill," in our last impression, that Messrs. G. van Abbott & Sons (Baden Place, Borough, London, S.E.) give away to members of the medical profession, on application, a little book on diabetic cookery, dietary tables, composition of cereals, fruits, &c., for diabetic patients, which will probably answer "Anchettill's" requirements.

STATISTICIAN.—There is considerable doubt whether the seasonable flooding of low-lying districts, near rivers, &c., as alleged, directly concerned with a high cancer mortality. In many districts in England a high death-rate from cancer prevails where no such condition is present. Moreover, it is doubtful whether cancer—presumably a parasitic disease—depends in any way upon the geological formation of our country.

A COMMON OCCURRENCE.

WHEN a patient calls to see you,
Very anxious to be cured,
And he quite forgets to fee you,
Say, now, can this be endured?
Take a lesson from the lawyer,
He's not one to trust to fate;
No advice, nor pen to paper,
Till he's sure of "Six-and-eight!"
Doctors still are far too willing—
Give advice they can't afford;
Public even grudge a shilling—
"Virtue is her own reward!"

A. D.

PENETRATOR.—The incidents described in the novel are improbable from a medical point of view.

TUMBLERS v. TANKARDS.

THE glass tumbler is quietly but quickly displacing the metal tankard. This is clearly shown by recent statistical returns. In 1891-2, among all the numerous drinking-vessels used in public-houses, the number of glasses stamped and verified by the officers of the London County Council only amounted to 290,240. Last year, however, the number had increased to 2,024,154. The reign of stout flagons, pewter tankards, and earthenware drinking-cups is giving way to the dominion of glass tumblers. And this, in spite of any lachrymation from the poets and sentimental chroniclers, is not without its hygienic advantages. The popular form of drinking-vessel is readily cleansed, dirt is more readily detected, and, moreover, allows of a freer and clearer inspection of its contents. All these are advantages to personal comfort and public health.

THE initials of a majority of London doctors start with "B" and "S." As might be expected, "Z" is by no means a popular initial, and has nearly disappeared from the "Medical Directory." In Scotland and Ireland the prevailing initial is "M," while in Wales it is "J," for which, of course, the Macs, the Murphys, and the Joneses are responsible.

A BOGUS M.R.C.S.

A MAN called Richard Hingston has been recently fined £50 and costs for falsely holding himself out to be a member of the Royal College of Surgeons of England. The defendant maintained his right to the title, alleging that he had lost the diploma, which could not be replaced except on personal application and identification. The magistrate, however, disbelieved his statement, and fined him accordingly. It may be found useful to make a note of the name!

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, JUNE 4TH.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Lewers, Dr. A. Lea, and Dr. Williamson. Mr. M. Robson: Notes of a Case of Primary Ovarian Gestation (showing the specimen). Paper:—Mr. A. Doran: Pregnancy after Removal of both Ovaries for Cystic Tumour.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Mr. Jackson Clarke: Clinique. (Surgical.)

THURSDAY, JUNE 5TH.

ROYAL SOCIETY (20, Hanover Square, W.).—8.30 p.m. Paper:—The President: The Sources of Phosphorescence.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital).—4 p.m. Clinical Cases will be shown.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.)

FRIDAY, JUNE 6TH.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (Society's Rooms West London Hospital).—9 p.m. Cases:—Dr. S. Taylor: A Case of Symmetrical Oedema of the Legs in a Man.—Dr. A. Saunders: Rheumatic Endocarditis in a Case of Transposed Viscera.—Dr. Beddard: Pulmonary Stenosis.—Dr. A. Saunders: Pulmonary Stenosis.—Dr. G. P. Shuter: A Case of Acromegaly.—Mr. J. E. Lunn: (1) A Case of Doubtful Congenital Dislocation of Hip in a Girl, with Skiagram; (2) A Case of Arteritis of the large Vessels with no Pulses at the Wrists in a Man; (3) Epithelioma of the Finger of a Man, with Sections for Microscope.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Dr. Jobson Horne: Clinique. (Throat.)

Vacancies.

Ayr District Lunacy Board.—Medical Superintendent. Salary £500, free house, coal, gas, vegetables, and washing. Applications immediately to Mr. J. E. Shaw, County Buildings, Ayr.

Bethlem Royal Hospital for the Insane.—Two Resident House Physicians for six months; board, residence, and washing provided, with an honorarium of £25. For fuller particulars, see Advt.

Bristol City Lunatic Asylum.—Medical Assistant, salary £140 per annum, with furnished apartments, board, and washing. Application to Edmund J. Taylor, The Council House, Bristol.

Cork Street Fever Hospital and House of Recovery, Dublin.—Assistant Registrar and Resident Medical Officer. Salary £60 per annum, with furnished apartments, board, and attendance. Immediate applications, to be addressed to the Chairman (see Advt.).

County Asylum, Whittingham, Lancashire.—Junior Assistant Medical Officer. Salary £150, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Fisherton Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Apply to Dr. Finch, Salisbury.

School Board for London.—Assistant Medical Officer, to give six half-days weekly to medical examinations. Salary £250 per annum. Immediate application (see Advt.).

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, fuel, lighting, and washing. Applications immediately to the Medical Superintendent.

Staffordshire County Asylum at Stafford.—Junior Assistant Medical Officer, salary commencing at £150 with furnished apartments, board, &c. Applications to the Medical Superintendent.

Staffordshire General Infirmary.—House Surgeon. Salary £120 per annum, with board, lodging, and washing. Applications immediately to the Secretary, Meyrick Road, Stafford.

Wilts County Asylum, Devizes.—Assistant Medical Officer. Salary £160, with board, residence, attendance, and washing. Applications immediately to the Medical Superintendent.

Appointments.

ALLBUTT, CLIFFORD, M.D., F.R.S., Examiner in Medicine and Therapeutics for the Indian Medical Service.

BOGER, WILLIAM HENRY, L.R.C.P. Edin., M.R.C.S., Medical Officer for No. 4 District of the Liskeard (Cornwall) Union.

BROWN, Major E. HAROLD, I.M.S., M.D., Clinical Assistant to the Chelsea Hospital for Women.

COWDEN, W. J., M.D., B.U.L., Certifying Surgeon under the Factory Act to the Dromore District of the County of Down.

HAMMOND, WILLIAM, L.R.C.P., L.M. Edin., M.R.C.S., Medical Officer for No. 6 District of the Liskeard (Cornwall) Union.

HARDING, NORMAN E., M.B., Ch.B. Edin., Locum Assistant Medical Officer to the Durham County Asylum.

LEITE, B. CALDER, M.A., L.R.C.P. Edin., F.R.S. Edin., Examiner in Pathology and Bacteriology for the Indian Medical Service.

LOW, V. WARREN, M.D., B.S., F.R.C.S., Surgeon to the Out-patient Department of St. Mary's Hospital, Paddington.

MACCARTHY, BRENDAN, M.D., B.Ch., B.A.O. Dub., Permanent Medical Inspector on the staff of the Local Government Board at Londonderry.

MARSH, HOWARD, F.R.C.S., Examiner in Surgery and Diseases of the Eye for the Indian Medical Service.

MURRAY, B. MILNE, M.A., F.R.C.P. Edin., F.R.S. Edin., Examiner in Midwifery and Diseases of Women and Children for the Indian Medical Service.

POWELL, J. F., M.R.C.S., L.R.C.P. Lond., House Surgeon to the Victoria Hospital, Folkestone.

Deaths.

COTMAN.—On May 27th, suddenly, Dr. John Sell Edmund Cotman, of 141, Minories, London, E.C.

DOWN.—On May 29th, at his residence at Streatham, Geo. Down, M.D., late of Kensington and Kensington, age 83.

HUNTER.—On May 25th, at 28, Tedworth Square, Chelsea, suddenly, from bronchitis and weakness of heart, Eliza Hunter, elder twin daughter of the late John Charles Hunter, M.R.C.S., L.R.C.P., aged 65.

LOCKHART-GILLESPIE.—At Walker Street, Edinburgh, on May 29th, 1902, Marjorie Edith, aged nine months, daughter of A. Lockhart-Gillespie, M.D., F.R.C.P.E.

OPTIC NEURITIS

WITH

PARALYSIS OF BOTH EXTERNAL RECTI

FOLLOWING

MIDDLE EAR DISEASE:

OPERATION, RECOVERY.

By MAYO COLLIER, M.S.LOND., F.R.C.S.Eng.,
Senior Surgeon to the North-West London Hospital.

ROSE H., *et.* 18, was admitted into the North-West London Hospital on June 10th last, with symptoms of acute suppuration in the right tympanic cavity following the removal of a small polypus from the ear. As an in-patient, four years ago, a polypus had been removed from the same ear with considerable benefit to an obstinate cough that had been unrelieved for a period of eight months. A discharge from this same ear was said to have existed since childhood.

This discharge apparently had existed off and on for fourteen or fifteen years, following an attack of measles. The hearing was defective, the watch being heard only at eight inches. There was no tinnitus. The left tympanum was normal, and the hearing good. The nose, naso-pharynx, and throat were healthy. The lungs, heart and abdominal organs were apparently free from disease.

On admission it was stated that ten days ago a polypus had been removed from the right ear by my colleague Mr. McGavin. Previous to this the patient had felt ill, had vomited occasionally, and complained of pain in the same ear and side of the face for the last three weeks. For the last three days severe frontal pain had set in, and with this double vision. The patient looked very pale and ill. The temperature on admission was 97.4°.

The pupils reacted well to light, and there was also slight internal strabismus on left side. Pulse was 60, regular, and of fair tension. The optic discs were swollen.

On June 12th the report by Mr. Pritchett, the house surgeon, was that the internal strabismus seemed more marked yesterday and to-day.

There was no pain or tenderness behind the ear. A yellowish-white offensive discharge was passing from the ear. The patient had only vomited once since admission, and this was after taking medicine.

13th.—The report was that the patient had only vomited once since last note; the frontal headache was not so severe. The pulse was 72, the temperature subnormal, no pain in ear, mental condition good, discharge not so offensive.

14th.—Had vomited twice yesterday; had complained of nausea all day. Paralysis of R. external rectus noted at 5 p.m. previous day.

15th.—Headache increased after the eye had been examined with the ophthalmoscope. Patient had vomited once, had slept well, and condition in other respects same.

17th.—Vomited twice, no headache, bowels very difficult to move.

18th.—About the same.

19th.—Dr. Collins, the ophthalmic surgeon to the hospital, reported: "Paralysis of both external recti, iridoplegia, with early neuro-retinitis in both eyes." There had been no vomiting or headache since last report, but the patient was drowsy, disinclined to take food, and was evidently losing ground.

After a further consultation with my colleagues, Dr. Harry Campbell and Mr. Jackson Clarke, I decided to take the less severe course of opening the mastoid and tympanum and clearing out the offensive contents. The patient was put under gas and ether, and a curved incision made behind the ear, and deepened till bone was exposed. The trephine was applied over the mastoid antrum, and on the button of bone being removed, offensive pus welled up from the opening. This was enlarged, and the antrum was found full of granulations, stinking, steatomatous concretions, and offensive pus.

The tympanum and epitympanic space were cleared of their contents, well cleansed, and disinfected.

No opening could be found leading into the cerebral cavity. The posterior wall of the auditory canal was removed, and the mastoid tympanum and epitympanic space made one cavity.

The wound in the skin and periosteum was closely adjusted, and the cavity drained by a large opening in the floor of the concha. The note on the day after the operation says: The patient vomited twice during the night. Did not sleep. Is now quite conscious. The ocular paralysis is the same as before operation. There is tenderness and pain behind the ear. The temperature is 97.4°; pulse, 80, regular, and fairly strong.

22nd.—The pain and tenderness behind the ear had subsided, there was no vomiting or headache, and the wound had healed. The discharge from the drain was small in amount, and quite sweet. Towards evening the patient vomited continuously, the vomit apparently coming up without any effort. The temperature was 99.4°.

On June 24th everything seemed satisfactory. Temperature was normal, and there was no headache, pain, or vomiting. Both eyes were in the same condition. The patient looks and feels better. On the 25th there was redness, swelling, and tenderness over the mastoid, just below the incision, and tenderness on the right side of the neck.

On the 26th a quantity of pus was evacuated from an opening behind and below the ear.

On July 1st, the report says: No change in ocular symptoms, no pain in head, and no vomiting. Temperature subnormal. Bowels moved naturally

once yesterday. Sleeps well, and takes all her food. On July 12th there was slight movement in both external recti, first noticed yesterday.

July 15th.—Both external recti were acting perceptibly.

27th.—Patient left the hospital. The ear was practically healed and free from discharge, and both external recti were moving nearly to their normal extent. There was still double vision and slight internal squint. General condition was good.

The optic neuritis was subsiding, and the vision had improved.

Being quite in the dark as to the pathology of the neuritis and rectus paralysis, I took the earliest opportunity of bringing the notes and facts before the British Laryngological Association, with the object of obtaining the opinions of the Fellows on the probable reading of the case.

Dr. Lodge said he had seen a similar case in a boy, *æt.* 10, with chronic mastoid disease. For several months afterwards, there was very marked double optic neuritis with paresis of both external recti. I presume this case recovered. My colleague, Dr. Hawthorne, made a most valuable contribution to the debate, and whatever light was thrown upon the pathology was due to him. He suggested a thrombosis of the cerebral sinuses or veins, or both, similar to what was very occasionally observed in cases of chlorosis, and in support of his suggestion related the following case:—

A girl, *æt.* 17, distinctly though not markedly anemic, and admitting some measure of menstrual irregularity. She was free from all evidence of disease in the thoracic and abdominal viscera, and ultimately made a complete recovery.

In short, with the exception of two facts, yet to be related, there was nothing to separate the case from the numerous examples of chlorosis seen by every practitioner. These two facts were diplopia and double optic neuritis.

The double vision was of sudden and recent origin (fourteen days), and was found to depend on a paralysis of the external rectus muscle of the right eyeball. Visual acuity was normal.

There was a slight degree of hypermetropia, and the ophthalmoscope revealed considerable optic neuritis in each fundus. Still later there were retinal changes in the macular region, with depreciation of visual power. After a few weeks' treatment, with rest and the administration of iron, normal vision was regained, the optic neuritis subsided, and the ocular paralysis entirely disappeared.

The lesson to be learnt from this case is a valuable one. Nausea, vomiting, pain in the head, and abnormal temperature may certainly be symptoms pointing to cerebral complications. Optic neuritis with implication of cranial nerves would undoubtedly be so. These, in conjunction with a chronic and stinking discharge from the ear, would naturally point to cerebral infection. Yet apparently this was not so, or if so, to such a limited extent as not to warrant interference with the cerebral contents.

Suicide of a Medical Resident.

An inquest was held at Guy's Hospital last week on the body of Edwin Stott, M.R.C.S., L.R.C.P., resident obstetric assistant at the hospital, who had committed suicide by cutting his throat with a penknife. A verdict of suicide when temporarily insane was returned, and the jury expressed their sympathy with the relatives.

Threepence a Case!

DR. JOSEPH DAVIES, one of the medical officers to the Swansea Board of Guardians, has just resigned his position, on the ground that his salary of £100 a year worked out at about threepence a case, his salary last winter having been entirely absorbed by cab fares.

NOTES ON A CASE OF BRAIN ABSCESS FOLLOWING MIDDLE EAR DISEASE. (a)

By R. H. WOODS, M.B., B.Ch., F.R.C.S.,
Laryngologist to the Richmond Hospital.

A PATIENT, *æt.* 28, a railway guard, was admitted to the Richmond Hospital. For a fortnight before his admission there was a discharge of fetid pus that ceased just before his admission to hospital, when he was attacked with a violent and sharp headache. He was then admitted to hospital under the impression that probably he was suffering from typhoid fever. His condition was as follows:—He looked very dazed, his pupils, especially the right, were dilated, but reacted slowly to accommodation and to light. The tongue was covered with a thick fur, brown in the middle and white towards the tip and edges. He was perspiring freely, and the body was covered with a sudaminous rash; he complained of great pain in the abdomen, especially in the right iliac region; a loud systolic murmur was to be heard in the mitral area, and could be followed into the axilla; the upper angle of the left posterior triangle of the neck, just at the base of the skull, was very tender, especially on firm pressure. He had no paralysis, motor or sensory. At Dr. O'Carroll's request I examined him on September 30th, when the body was almost bathed in sweat. His breath had a very disagreeable odour, and the teeth were covered with sordes. He frequently lost consciousness, was unable to recognise his relatives, and was very restless, getting out of bed and tossing the clothes about. Cerebration was slow; even in his more lucid moments it was difficult to get him to answer questions coherently. When asked his address he gave a former one, and he was unable to recognise familiar objects, though he understood and could tell their functions. Thus when shown a bunch of keys he could not by any effort think of their name, though when asked what they were for he had no hesitation in replying that they were for opening locks of doors. Similarly, when shown a pocket-knife, without being able to say what it was, he could tell that it was useful for cutting tobacco, but, if in the same moment he was shown tobacco, he had the same difficulty in naming it as if he had not used the term at all. Or, if one persisted in the question, he might call it an overcoat or a walking stick, or something equally absurd, though he was quite aware it was used for smoking or chewing. His pulse was feeble, but not frequent. He was emaciating rapidly in spite of the fact that he took fluid nourishment fairly well. He complained of thirst, a bad taste in the mouth, and of frontal and occipital headache. He was on one occasion observed to have a slight degree of opisthotonos during a rigor. Ophthalmoscopic examination showed that he had double optic neuritis. The urine (*sp. gr.* 1037) was acid, and there was a precipitate of urates and a trace of albumin, but no sugar. His temperature was now taken every four hours, and the difference between the curve on the ordinary clinical chart and that of the four-hourly chart was most marked and most instructive. The ordinary chart, which, for curiosity's sake was marked at the same time, showed a curve varying two or three degrees from day to day without any regularity, and so devoid of character that absolutely nothing could be learnt from its inspection or, worse still, whatever was learnt was wrong. Some idea of its deception may be formed from the fact that on October 3rd, when the patient was at his worst—as shown by the four-hourly

(a) The subject of a communication to the Otological Society at its meeting in Dublin, May 31st, 1902.

chart—his maximum and minimum temperatures for the day differing by 8.5° F.—the ordinary chart told nothing more than at a certain hour in the morning his temperature had been 98° F., and in the evening 99° F., a not very serious condition, if the chart was the only guide to one's opinion. This is as good an illustration as one can have of the danger of using ordinary charts where intracranial pyogenic trouble is suspected. On examining the four-hourly chart it will be seen that on the days immediately preceding the first operation there was the most marked similarity between the sequence of events. On each day the morning temperature was subnormal by a degree or even two, in the middle of the day a rise coincident with rigor occurred, the temperature passing 104° F. followed by a fall to subnormal again as night approached. After we had thus observed him for a few days, there seemed to be no doubt that whether he had typhoid fever or not he was suffering from intracranial mischief, the result of the suppurative ear disease, and from the character of the temperature chart, the tenderness in the posterior triangle of the neck, and other symptoms a diagnosis was made of sigmoid sinus thrombosis.

On October 5th, 1895, the patient being too ill for removal to the surgical hospital, he was chloroformed in bed. A vertical incision was made immediately behind the left ear, and the bone being removed from Birmingham's triangle with mallet and gouge, the mastoid antrum was exposed. From this cavity a quantity of foetid cholesteatomatous debris and granulation tissue was removed and exit given to a few drops of greenish pus. The antral walls were inspected but no matter could be seen escaping. The bony opening was then enlarged backwards until the groove for the sigmoid sinus was opened up. The sinus was split open and the clot removed. The dura mater was then lifted gently away from the bone in various directions. An abscess was found on the cerebellar aspect of the petrous bone and about two drachms of foetid pus evacuated. The cavity was syringed out with carbolic lotion, a drainage-tube inserted, and the outer portion dressed with iodoform gauze. The patient was much benefited by the operation, but not, however, as much as was expected. His mental condition remained blurred. It was concluded that there was yet another lesion, probably brain abscess, unrelieved. The symptoms pointed rather to the cerebrum than the cerebellum as the seat of the trouble, but the fact that I had already found pus in cerebellar fossa made me believe the cerebellum to be the more likely place. I, however, decided to place the exploratory wound so as to have access both to cerebrum and cerebellum. The second operation was performed on October 7th. A trephine hole was made behind and above the mastoid process opening, directly over the lateral sinus, so that access could be had both above and below the tentorium. Great care was taken to prevent contamination from the mastoid wound which was now discharging foetid pus. A hollow needle was passed into the cerebellum three times with negative results, and consequently it was decided to try above the tentorium. The punctures in the dura mater were therefore sealed by being liberally sponged with compound tincture of benzoin to ensure against contamination from the neighbouring pus. In order to get quite clear of the lateral sinus, it was found necessary to enlarge the trephine hole slightly upwards by taking a half-moon out of its upper edge; this having been done the temporo-sphenoidal lobe was tried, and at the third insertion of the needle we were rewarded by the appearance of pus. A crucial incision was made in the dura mater, and a pair of catch forceps entered along the track of the needle and redrawn with the

blades open. Exit was thus given to over four drachms of horribly foetid pus, together with numerous brain sloughs. The cavity was washed out with a weak carbolic lotion, and a drainage-tube inserted. Notwithstanding the fact that he had a mitral murmur, we felt bound to give him chloroform rather than ether at both operations on account of the unsuitability of the latter in such cases, and it is worth noting that he took the anæsthetic perfectly. The patient made steady if somewhat slow progress to complete recovery. He remembered nothing of the two operations, nor the fact that he had consented to their performance. The only permanent effect left behind is that though his mental condition is perfectly clear he is inclined to be what I would call "huffy." On the slightest provocation he is inclined to consider himself injured. He was discharged from hospital on December 14th, 1896, and returned to his work a couple of weeks afterwards. About twelve months ago he was transferred from one station to another, and came to the conclusion that the transference was brought about by some enemies of his, although, as a matter of fact, he was getting lighter duty than what he had been doing. Sooner than submit to it he resigned, but was very sorry for it afterwards. At present he is in full possession of all his faculties.

The Ingleby Lectures

ON

CHRONIC HYPERTROPHY

OF THE

FAUCIAL AND PHARYNGEAL LYMPHOID OR ADENOID TISSUES.

Delivered at the University, Birmingham, May 27th.

By F. MARSH, F.R.C.S.Eng.,

Surgeon to the Queen's Hospital and to the Ear and Throat Hospital, Birmingham.

ABSTRACT OF LECTURE I.

AFTER due mention of the life and labours of Dr. Ingleby, the lecturer proceeded, in accordance with the wishes of the founder, to speak of conditions peculiar, at all events to a great extent, to childhood, viz., Hypertrophy of the Faucial and Pharyngeal Lymphoid or Adenoid Tissues:—

I have selected this subject as being one of great interest to those engaged in the general work of our profession and as one upon which I am able to speak with some authority. The structure of these lymphoid tissues consists of a network of loose connective tissue in the meshwork of which are lymphatic follicles and also, according to Sajous, some conglomerate glands. They are covered with cylindrical epithelium and are richly supplied with blood vessels. They occur as distinct and well-defined, rounded masses between the anterior and posterior pillars of the pharynx—the faucial tonsils—as an irregular layer across the upper part of the posterior wall and vault of the naso-pharynx—Luschka's tonsil—and as scattered patches over the posterior and lateral walls of the pharynx, sometimes in the latter situation extending downwards as distinct bands from Luschka's tonsil, behind the posterior pillars of the pharynx. There are also two patches at the base of the tongue in the glosso-epiglottidean fossæ known as the lingual tonsils, but which are outside the scope of these lectures. These tissues during inflammatory catarrhal attacks increase in size, and are also very prone under certain conditions to overgrowth or hypertrophy—and it is this latter

condition alone as distinct from the former that I purpose to speak about.

The faucial tonsils when hypertrophied are generally spoken of as "enlarged tonsils." Hypertrophy of Luschka's tonsil has gone by many names: "adenoid vegetations in the naso-pharynx," "adenoid growths," "post-nasal growths" (or "growths" for short), "post-nasal adenoids," and now "adenoids." This last is a short and convenient name, and so long as the true nature of the condition is kept in mind there can be no valid objection to its general use. "Enlarged tonsils and adenoids" is now a common way of denoting this hypertrophy of the two groups of tonsils. Hypertrophy of the scattered patches and lateral bands in the pharynx is usually termed "chronic follicular or granular pharyngitis." It may be said that there is practical agreement that "enlarged tonsils and adenoids" are usually associated, that they occur essentially in childhood and adolescence, and that they are almost equally prevalent in the two sexes. Considerable diversity of opinion, however, exists as to the influence or importance of most of the assigned causes—viz., heredity, scrofula, lymphatic temperament, climate, anterior nasal stenosis, cleft palate, vaginal secretions at birth, the acute exanthemata, whooping-cough, and nasal and naso-pharyngeal catarrh. Heredity (including both the transmission of a special tendency to this hypertrophy, of which some well-marked instances have come under my notice, and the liability of children with a tuberculous family history to lymphatic affections) is certainly a cause, and that it may be the only one is shown by the occasional manifestation of the symptoms from the time of birth. Climate is undoubtedly a most important factor. The atmosphere in large cities and for miles around is laden, more or less, with irritating ingredients—particles of carbon, acid fumes, &c.—and the constant passage of these impurities over these tissues, so sensitive to stimulation, is sufficient in itself to produce over-growth. Add to this a winter climate—though the word "winter" might almost be omitted—of rapid alternations of temperature, periods of cold winds, wet, fog, and gloom, with only occasional intervals of dryness and sunshine, and you have ideal conditions for the production of acute catarrhal inflammations—rhinitis, adenoiditis, and tonsillitis. Let only these attacks be repeated, or, above all, neglected, as is so often the case with the masses, and you soon have a chronic tonsillitis and adenoiditis with the inevitable hypertrophy as a sequel. A cold, moist climate, clay sub-soil, &c., is a sufficiently exciting cause altogether apart from the effect of the vitiated air of large towns. Measles, scarlet fever, whooping-cough, and influenza are active exciting causes, the first symptoms often dating from one of these illnesses. Anterior nasal stenosis is considered by some authorities to be a predisposing and even an exciting cause of adenoids, but a careful examination of a very large number of children with adenoids sufficient to cause almost complete nasal stenosis has shown the nasal fossæ to be generally patent, and only stenosed anteriorly in cases where catarrh has been present as well. In fact, my observations have led me to the conclusion that anterior stenosis from turbinate congestion, &c., is either concurrent with an adenoiditis or a result rather than a cause of the hypertrophy. Deflections of the septum sufficient to cause anything like complete stenosis are very rare in children. To sum up, heredity, bad climate, bad hygiene, bad feeding, and neglected colds will account for the majority of cases.

The age at which the hypertrophy takes place, or rather causes symptoms requiring treatment, is shown by the following table of 1,000 cases operated upon by me at the Birmingham Ear and Throat

Hospital from January 1st, 1899, to January 15th, 1902—a little over three years. Of the 1,000 cases 556 of the patients were females and 444 were males, and 816 were under and 184 were over 16 years of age. The youngest patient was 14 weeks old and the oldest was 36 years old.

Table of 1,000 Cases of Hypertrophy Operated upon at the Birmingham Ear and Throat Hospital between January 1st, 1899, and January 15th, 1902.

Age.	Number.	Age.	Number.
In the first year ...	9	In the twelfth year ...	57
" second year ...	17	" thirteenth year ...	49
" third year ...	48	" fourteenth year ...	41
" fourth year ...	74	" fifteenth year ...	34
" fifth year ...	105	" sixteenth year ...	39
" sixth year ...	76		
" seventh year ...	71		816
" eighth year ...	55	Over 16 years of age ...	184
" ninth year ...	51		
" tenth year ...	53		1,000
" eleventh year ...	37		

An analysis of the 816 cases among patients under 16 years of age shows that the greatest number were in their fifth year, those in their sixth, fourth, and seventh years ranking next. Considerably over one-third, therefore, of the 816 cases occurred in these four years.

Although in children enlarged tonsils are nearly always associated with adenoids it will be most convenient to consider the special characteristics, symptoms, and treatment of each separately.

The clinical importance of enlarged tonsils has been recognised for a great number of years, but symptoms were assigned to them which were in reality due to adenoids—then unknown. Consequently, tonsillotomy often failed to give more than partial relief and became to some extent discredited. Disappointed parents attributed to the operation the poor development of the thorax, the sexual organs, and mammae in girls, and the tradition still lingers. An occasional protest against removal of the tonsils is still made on these grounds.

In size, shape, and consistence enlarged tonsils vary much, but they may be arranged in three groups: (1) where the hypertrophy is chiefly in the horizontal diameter—the projecting tonsil; (2) where the hypertrophy is chiefly in the vertical diameter—the elongated tonsil; and (3) where the hypertrophy is chiefly in the antero-posterior diameter—the broad, sessile, or flat tonsil. These types may, and often do, approach each other and are found in combination with one another, the most frequent being the elongated with the projecting. This occasionally has in exaggerated forms the appearance of a double tonsil. This is probably due to the persistence of the lower of the two furrows which, according to Killian (a) are present at birth. Persistence of the upper furrow is more common, and without careful examination its circular edge might be mistaken for the edge of an excavated ulcer. (b) The surface of the tonsils may be even and of a fairly normal aspect or ragged with large and irregular openings into the crypts. Very rarely it is papillated, as in these two tonsils removed from a girl, æt. 5, where the surface is covered with projecting papilli, some half an inch long, and an appearance that might be mistaken for multiple papillomata. The consistence may be normal, dense and fibrous, or soft and mushy, according to the predominance of the fibrous or lymphoid tissues. The older the patient the more fibrous the tissues, as a rule, but much depends on the occurrence and length of chronic inflammatory attacks. The secretion from the follicles may be caseating and retained in the crypts and recesses of the tonsils. The pillars of the fauces may from previous inflammatory attacks be

(a) Archiv für Laryngologie, vol. vii.
(b) Dundas Grant: Brit. Med. Jour., vol. ii., 1901

more or less adherent to, and in marked cases almost blended with, the tonsils, especially in the sessile variety.

The symptoms caused by enlarged tonsils may be classified as (1) obstructive, (2) catarrhal, and (3) reflex.

1. *Obstructive Symptoms.*—The size alone of the tonsils may cause considerable mechanical trouble. Swallowing when the projecting tonsils are in apposition is rendered difficult—a special effort has to be made by the child to get the food out of his mouth, and in extreme cases fluid only can be swallowed, and that with difficulty. Under similar conditions buccal respiration is much impeded (a serious matter if nasal stenosis from adenoids coexists) and the voice is thick and indistinct. In some cases the palate is pressed upwards to such an extent that the action of the palato-tubal muscles is impeded and deafness results from imperfect middle-ear aëration.

2. *Catarrhal Symptoms.*—The crypts and recesses, especially in those forms where lymphoid tissue predominates, are suitable places for the lodgment of the catarrh microbe—the pneumococcus and other micrococci akin to it—and form “centres” for catarrhal attacks. The microbe, probably ever present, waits only for some diminution of tissue resistance, such as an exposure to cold will produce, to exert its maleficence. The catarrh may either keep localised, causing tonsillitis and exaggerating or producing obstruction, or in those of less resisting power may extend to adenoids, if present, causing adenoiditis, and from there to the middle ear or to the nasal cavities or downwards to the organs of respiration or digestion, according to the constitutional peculiarity or tendency of the individual. Owing to absorption of toxin generated by the catarrh microbe or the passage of the microbe itself through the lymphatics, the lymphatic glands corresponding to the tonsils (the upper set of the deep cervical group) often become inflamed and enlarged. In the slighter cases the glands enlarge during catarrhal attacks and subside with the disappearance of the catarrh. In others the glands do not disappear on the subsidence of the catarrh, but remain distinctly enlarged and become larger and tender on pressure during every subsequent catarrhal attack but with little or no tendency to break down or to suppurate. In the more severe cases there is from the first a decided tendency for the glands to break down and suppurate. This variation is due to the difference in the resisting power of the individual and the intensity and amount of the toxin absorbed. Tonsillotomy prevents these attacks and if promptly done at the outset may arrest the progress towards suppuration. Glands, too, that have been enlarged for a considerable length of time often gradually diminish in size and disappear after tonsillotomy.

3. *Reflex Symptoms.*—The only reflex symptom that I have been able to attribute to enlarged tonsils is “cough.” This may be short, dry, or hacking in character and almost constant, or occurring in paroxysms and distinctly spasmodic in character. It is difficult when “adenoids” are also present to say to which group the credit of the reflex should be given, but every now and then cases occur—such as the following—which seem to point definitely to the tonsils as a cause.

The diagnosis is simple. The possibility of tonsillitis accounting for the whole or part of the symptoms must be kept in mind; the presence of febrile symptoms and the inflamed aspect of the tonsils will clear up this point. A thorough examination should in all cases be made, the surface and condition often being of more importance than the actual size. When the examination has been completed (which should in-

clude the buccal cavity, pharynx, naso-pharynx, nose, ears, and lymphatic glands) the tongue depressor should be pressed backwards until the child retches; this brings the tonsils into relief and, especially in the flat forms shows, their full extent and condition.

The treatment resolves itself into the question of operation or not. The fact that the tonsils project a little more than is usual does not render tonsillotomy either necessary or advisable. It should be undertaken solely for the relief of some definite symptom or symptoms which cannot be satisfactorily treated by other means.

I consider operative treatment necessary when the tonsils are so large that they mechanically cause some obstructive symptom, even if otherwise healthy—when they are the centres for frequent or prolonged catarrhal attacks, or acute inflammatory attacks; when they are the cause of lymphadenitis; when the crypts and recesses are filled with caseating secretion which does not yield to treatment; when they are the probable cause of a troublesome reflex cough. I consider it advisable when an adenoid operation is necessary, even if the hypertrophy is not very marked.

The operation of tonsillotomy in children is now seldom performed, except under an anæsthetic and in conjunction with an adenoid operation. The question of the anæsthetic, therefore, will be dealt with when the latter question is considered. Tonsillotomy alone may, however, be necessary in older children. Then local anæsthesia induced by applying a 10 per cent. solution of cocaine or eucaine is all that is needed, but if the child is nervous and sensitive nitrous oxide gas may be employed and will give ample time.

Various methods have been devised for the removal of the enlarged tonsils—a blunt-pointed bistoury and Volsellum forceps were used in early times and are still by some surgeons. The operator stands in front of the patient, seizes the left tonsil with the Volsellum forceps, which are held in the left hand, and draws it towards the middle line and removes as much tonsil as possible by cutting upwards with the bistoury. If the surgeon is ambidextrous the right tonsil may be removed in a similar manner, the forceps now being held in the right hand; but if not ambidextrous it will be necessary for him to stand behind the patient. For a tractable child with projecting tonsils this method may be satisfactory, but the combination is not a common one, and doubtless it was to overcome this difficulty that guillotines were invented. The earliest forms were very ingenious, and consisted of a concealed ring knife and a transfixing spear, so attached that the tonsil was levered inwards whilst the ring knife cut through it. I am under the impression that the credit of this invention should be given to a French surgeon named Matthieu. His name is still associated with the instrument, although there have been many modifications with many names attached to them—Luer, Beehag, &c. To the late Sir Morell Mackenzie we owe the introduction of the spade guillotine, and this type, though modified in many ways, and not always to the improvement of the instrument, has nearly displaced the French one. It is simple in construction, and can be used with the patient in any position, and with or without light. If properly used no difficulty will be found in removing the greater part even of the flat forms of tonsils. In my own practice I always use Mackenzie's pattern, from five to six inches in length, and with a well-balanced metal handle. The method of using it is all-important. If the patient is in a sitting posture the head must be steadied by an assistant, who must make steady pressure just beneath and behind the angle of the lower maxilla at the time of the removal of the tonsil. The operator should stand in front of the patient for the removal

of the left tonsil, to the right and slightly behind for the removal of the right tonsil, unless he is ambidextrous or has a reversible handle to the guillotine. The guillotine should be warmed by dipping it in hot water. The first step is the proper engagement of the tonsil, and here care must be taken to first encircle the lower edge. The second step is to press firmly the guillotine outwards, and the third to press sharply home the blade with the thumb. These movements, though distinct, should be performed almost as one—steadily but rapidly.

The causes of inefficient removal or failure are due generally to a non-recognition of the first two movements and to the use of too large a guillotine, or more rarely to adhesions between the tonsils and the pillars of the fauces preventing proper engagement with the guillotine. When this latter is the case it is sometimes necessary to separate the adhesions prior to tonsillotomy. After removal the severed tonsil generally adheres to the guillotine, and very seldom gives trouble by falling into the patient's pharynx, even in the lying down position. If the patient is in this latter position both tonsils can be removed by the operator standing on the right side or behind the head for the removal of the right tonsil if he prefer. If the patient is under an anæsthetic a gag must be used, and it may be necessary to change it to the other side of the mouth after the removal of the first tonsil. If, however, it is carefully placed and managed by an anæsthetist who has had experience in these cases the change is seldom required. In a combined tonsil and adenoid operation the question arises which should be first removed. This depends upon the size of the tonsils; if these are so large that they would interfere with the free exit of the curette or other instrument with the adenoids they must be operated upon first, but if not it is better first to remove the adenoids.

After the operation no portion of tonsil should be seen projecting beyond the pillars of the fauces—preferably there should be a distinct hollow. Removal of a superficial slice is not enough; the greater part of the enlarged tonsil must be removed, a small pad only being left. It has happened to me on three or four occasions to enucleate completely a tonsil with the guillotine, the blade—probably not over sharp—slipping over a convex surface not so embedded as usual. I have not known of any detriment following this, such as lodgment of particles of food in the hollow left, injury to the internal carotid by a sharp fish or other bone caught between the pillars of the fauces, or undue approximation of the pillars of the fauces. These are possible consequences, and to obviate them a small pad of tonsil tissue should be left.

Other methods of operation—viz., with tonsil scissors, the cold wire snare, the *écraseur*, the galvanocautery snare, morcellement, and crushing—may be occasionally advisable in adults, but as yet I have not found it necessary to adopt any of them in children. In a few cases in older children I have, when tonsillotomy has been much dreaded by anxious parents, employed ignipuncture with the galvanocautery. A straight point is used and inserted into the substance of the tonsils, previously well cocaineated, at a bright red heat. It is not advisable to make more than two punctures at one sitting, and usually three or four in all will suffice to achieve the desired result.

The risks of a well-performed tonsillotomy are practically *nil*. It is impossible to wound the internal carotid artery either with a guillotine or with a blunt-pointed bistoury if ordinary care be used (a sharp-pointed one should never be used). The immediate hæmorrhage is at times free, especially if the whole of the tonsil is by any chance enucleated,

but it generally ceases of itself, and I have never yet had occasion to tie a vessel or ever had any anxiety about it. Recurrent hæmorrhage—that is to say, hæmorrhage occurring within the first twenty-four hours after operation—is more serious; a large quantity of blood may be swallowed before the patient or the nurse is cognisant of it; in one or two instances I have known it continue to syncope before medical assistance could be obtained.

The first step in the treatment is to ascertain exactly the origin of the hæmorrhage, whether it is from a single vessel, in one or both tonsils, or a general oozing from one or both. If the former a pair of Spencer-Wells' forceps should be clamped on and left *in situ*, but I have never had occasion to do this in the case of children. If caused by a general oozing the bleeding surface should be well swabbed with adrenalin solution, and chloride of calcium in from 5 to 10 grain doses, according to the age of the patient, should be given every hour until the bleeding stops. If the application of adrenalin does not suffice firm pressure should be made over the bleeding stump with a pad of lint, with or without adrenalin, and kept in position either by the finger or a pair of forceps, but I rely much on the calcium chloride. In one case where there was a distinct hæmophilic history I gave it for some days prior to the operation with a very satisfactory result, and I now frequently give it to adults beforehand as a precautionary measure.

True secondary hæmorrhage is rare, but it does occasionally take place, even as late as the sixth day, from the opening up of a small vessel during the separation of a slough.

Another risk, also a small one, is sepsis, with its probable complication, septic pneumonia. It is impossible to sterilise the patient's throat prior to operation, but possible sources of infection, such as carious teeth, alveolar abscess, &c., should be looked for and removed. Instruments can be and should be sterilised, and the surgeon's hands rendered as aseptic as possible. Sponges, if used, should receive the most careful cleansing and sterilising; personally, I never use them, but employ a swab of cotton lint wrung out of hot water for what mopping out is needed.

The patient's condition at the time of operation is also important. The operation is one of election, and a time should be chosen when the patient is well and free from any febrile condition—when his tissues are in a fairly good state of resistance. The better his resisting powers the smaller the risk of sepsis. It need hardly be said, too, that the patient should be placed in the best hygienic surroundings that his circumstances will admit.

The treatment after operation is simple. The essentials are: (1) Avoidance of exertion immediately afterwards (a fertile cause of recurrent hæmorrhage); (2) an equable temperature during the healing process (to prevent catarrhal attacks); (3) suitable diet; and (4) the use of a cleansing wash. The operation should therefore be performed at home or in a hospital, and the child should be put straight to bed afterwards in a warm room and kept there for at least three days and indoors the rest of the week unless the weather is exceptionally warm. Nothing hot or hard should be given; the first day sterilised milk only—cold or lukewarm; slop diet the next two days; then, if the child is doing well, ordinary light diet. If the throat is very painful when swallowing one-twelfth of a grain of cocaine lozenge may be given before meals, or the throat may be sprayed with a weak cocaine solution, but this is seldom needed. After food the mouth and throat should be washed out or sprayed with an alkaline antiseptic solution.

Should sepsis happen an examination will show

the stumps of the tonsils covered with an ashy grey slough. The parts which surround the palate, uvula, and pillars of the fauces will be red, swollen, and flecked with whitish patches, the tongue will be furred, and the breath offensive, the cervical glands will be painful and enlarged, the throat will be painful, especially on movements of deglutition, febrile symptoms will be marked, and possibly ushered in with a slight rigor. When this happens a full dose of calomel should be given at once and after its action quinine or perchloride of iron. If the child is old enough and able to gargle the mouth and throat should be frequently washed out with an alkaline antiseptic wash, such as borax, chlorate of potash and thymol, or with solution of chlorine. If the child is unable to gargle the throat should be frequently sprayed with a similar solution and iodoform or one of its odourless substitutes insufflated over the sloughy surface. The strength of the child must be maintained by good nursing and feeding, and a careful watch should be kept for any lung or other complications. A sloughy surface is often present in delicate children, but without any spreading inflammation or febrile symptoms, and it clears gradually without special treatment as the healing progresses, and can hardly be called septic. Whenever sloughing occurs there is the possibility of secondary hæmorrhage during the separation process.

In the slighter cases, where operation is not needed, and in the few where for some reason or other operation is inadvisable, local and constitutional treatment should be instituted; cleansing gargles or sprays should be used, followed by the application of astringents, glycerine, and tannic acid, hydrastis, &c., and iodine and iron, cod-liver oil, malt, and hypophosphites should be given internally. A long stay at the seaside or in the country often brings about a remarkable change for the better.

Clinical Records.

JERVIS STREET HOSPITAL.

Notes on a Case of Acute Ascending Paralysis.

Under the care of W. J. THOMPSON, M.D.,
Physician to the Hospital.

J. A. was admitted to Jervis Street Hospital on March 5th with the following history:—He was æt. 62, had always been strong and healthy, denied ever having any venereal disease, and had a good family history. He was a drayman by occupation, and as such was frequently exposed to heavy wettings, severe colds, and all the ordinary variations of this climate. This winter he felt the cold more than any other season. He was temperate in his habits, and had been in the same employment for thirty-two years.

For some days before admission he felt his feet and legs "numb," with a prickly sensation in them, and he had slight difficulty in walking. This condition, he states, was most marked in the morning. The day before admission he had to give up work, as he was unable to walk. When he came under observation the legs were paralysed as far as the knees; the superficial and deep reflexes were lost, and there was no disturbance of sensation. He did not complain of any pain in the legs, nor was there any on deep pressure. There was no pyrexia; all his organs were healthy, and no splenic enlargement could be made out. On March 8th (three days after admission) the paralysis had extended up the whole leg, and was preceded by the numbness and prickly sensation. On the 12th the muscles of the back became affected, and he lost control of the sphincter of the bladder but not that of the rectum. On the 18th the arms, the diaphragm, and intercostal muscles were engaged. He gradually developed into a state of mental dulness and had a good deal of low delirium, especially at night. His condition

was that of universal palsy, save for a little respiratory power. He was, however, able to swallow fluids but not solids. An examination of the blood at this time revealed nothing unusual, the fundus oculi were practically normal, and there was no rise of temperature. The electrical reactions of the muscles were not affected. It was now noticed that the area of splenic dulness became enlarged, and this about three weeks from the first onset.

He remained in this condition for two weeks, when he commenced to slowly improve—the order of recovery of the muscles taking place is the opposite to that of their invasion. The mental dulness gradually left. In a couple of weeks after the first sign of recovery he regained power of the bladder, and about the same time the splenic dulness diminished. The reflexes also slowly returned, and at the present moment the patellar reflex is, if anything, increased. The patient just now, eleven weeks after the initial attack, is almost completely recovered.

The points of interest about the case are:—

1. The age of the patient.
2. The definite history of exposure to cold.
3. The enlargement and diminution of the splenic area.
4. The complete control of the rectum and not of the bladder.
5. The slight increase of patellar reflexes at present.

The general treatment adopted was that usually followed in cases of myelitis, and the drugs used were ergotin, arsenic, and strychnine.

A CASE OF DOUBLE PERFORATION OF THE MEMBRANA TYMPANI, THE RESULT OF BEING STRUCK BY LIGHTNING. (a)

By H. MACNAUGHTON-JONES, M.D., F.R.C.S.

THE details of the case are briefly as follows:—On December 24th last an officer was sitting on the floor of his tent on blankets, drinking tea from an iron cup. A storm was passing at the time. He was not conscious of anything until he found himself, as he expressed it, paralysed, with the exception of his left arm. He thinks that two hours may have elapsed between the time of his being struck until he was found. He was revived with brandy and strychnine injections, and vomited freely during his transit to the hospital three miles away. The hair on his left temple was burned, and also that on the pubes. There was an abrasion of the right breast, and a stripe about an inch and a half broad running down from this to the penis, from which it deflected over the right thigh, terminating in a mark "with a cut like a whip." There were still marks remaining on the skin when I last saw him at the end of March. There were also burns on both shoulders over the scapula, and another small one behind the right shoulder. The excoriation over the left shoulder was considerable. The hearing of the left ear was seriously affected, and the perforations were discovered a few days later. Curiously enough, the tent was not injured, and the flash had apparently struck within a few yards of it. When I saw him the entire tympanic membrane was injected, and of a deep red colour. There were two perforations present, one in the posterior superior quadrant, and the other below the umbo. The watch was heard just off contact, and a whisper close to the ear. The most troublesome symptom was a rather loud tinnitus. Some uneasiness and distress, hardly amounting to pain, were felt in the ear. There were no other evidences of nerve impairment elsewhere. There was little to be done in the way of treatment. I made periodical application of a weak solution of nitrate of silver to the membrane, keeping the ear protected with antiseptic gauze, and using occasionally Lucas's inflator. When I last saw him at the beginning of April the hearing was greatly improved, a whisper was heard at some twelve feet away, and, as estimated by Edelmann's Galton pipe, a tone of 10,000

(a) Read before the Otological Society, May 31st, 1902.

vibrations per second, as compared with 35,000 in his unaffected ear.

The case is interesting, not only from the point of view of the marvellous escape he had, but also as it is the only one of which I am aware in otological literature in which perforation of the membrana tympani has been found as the result of lightning.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, JUNE 4TH, 1902.

PETER HORROCKS, M.D., President, in the Chair.

OVARIAN PREGNANCY.

PROFESSOR A. W. MAYO ROBSON (Leeds) read a short communication on a case of this description, and showed the specimen. A diagnosis of ectopic gestation was made before operation, and when the abdomen was opened free blood was found in the peritoneal cavity. The ovary was found lying above the tube, and over the ovary was a small mass of blood-clot, in the middle of which was the ovum, which had clearly been extruded from a small cavity of corresponding size in the substance of the ovary. The tube was perfectly normal. The specimen had been carefully examined by Mr. S. G. Shattock, who confirmed the view that it was a case of ovarian pregnancy. This made the fourth authentic case now reported, the three previous ones being those of Van Tuschenbroek, Croft, and Littlewood and Anning.

Mr. ALBAN DORAN remarked that even now that the possibility of ovarian pregnancy had been definitely demonstrated, it was very difficult to prove that a given case was an instance of ovarian pregnancy. The fact that the tube appeared to be normal was not in itself conclusive, for he and Mr. Bland-Sutton had shown that after the expulsion of a mole the tube might resume its normal dimensions and appearance.

Professor MAYO ROBSON concurred in Mr. Doran's remarks, and added that it was not possible to demonstrate ovarian pregnancy except in early and recent cases. An incontrovertible case must fulfil the requirements recently laid down by Mr. Bland-Sutton.

AFTER-RESULTS OF REMOVAL OF THE CERVIX FOR CARCINOMA.

Dr. A. H. N. LEWERS showed microscopic sections from eight cases of cancer of the cervix in which the patients had remained free from recurrence for periods of four to fifteen years. The time since operation in the eight cases was as follows:—Fifteen years, twelve years (two cases), nine years, seven years, five years, and four years (two cases). In all except one of the twelve-year cases the growth was a squamous-celled carcinoma, the exception being a columnar-celled variety. It happened that in all these cases the operation performed was amputation of the cervix. In his later cases he had generally done vaginal hysterectomy, not because it gave much better results as regards prognosis but because leaving the body of the uterus was apt to be followed by bad sequelæ, from contraction of the uterine canal, dysmenorrhœa, or retention and suppuration of menstrual products in the uterine cavity. He considered that four years' freedom from recurrence might be regarded as a cure. Certainly he had not met with a case in his own practice in which recurrence took place after four years.

Professor MAYO ROBSON said that some years ago he used to perform amputation of the cervix for early carcinoma; some of these patients were living now, and he had asked himself if they were not making a mistake in doing hysterectomy, since the results of the latter operation did not appear to be very much better than those of amputation of the cervix.

Dr. William Duncan and Dr. Robert Boxall discussed the subject, and Dr. LEWERS replied.

Dr. ARNOLD LEA (Manchester) showed a "solid ovarian tumour," which he considered to be a folliculoma.

Dr. WILLIAMSON showed "an unusual form of ectopic gestation."

Dr. CUTHBERT LOCKYER showed a specimen of "squamous-celled carcinoma of the cervix," which was in striking contrast to those shown by Dr. Lewers, inasmuch as rapid recurrence took place within three months, and the patient died within five months of the operation.

Dr. WILLIAM DUNCAN showed a "myoma of the uterus" weighing 18 lbs. which he had removed that morning. The case was of special interest because the tumour took on rapid growth after the menopause.

PREGNANCY AFTER REMOVAL OF BOTH OVARIES FOR CYSTIC TUMOUR.

This paper was read by Mr. ALBAN DORAN, who had met with an instance of this rare and remarkable occurrence. The history of the case was as follows:—A woman, æt. 25, after bearing one child, underwent ovariectomy for a multilocular adenomatous cystic tumour of the left ovary. She then bore four more children, and afterwards, when æt. 39, came under the author's care, and he removed a similar tumour of the right ovary. The base required enucleation; part of the capsule was ligatured like a pedicle with silk, and the greater portion cut away, but in that part no trace of the Fallopian tube could be detected. A small tubercle on the left of the uterus was the sole remnant of the left appendages. After convalescence the period recurred, and continued till the patient became pregnant and bore a child at term two years after the operation. The period then returned, and ceased abruptly when the patient was forty-five. The consequent menopause symptoms were distinct though mild. The author briefly reviewed a few cases already reported where pregnancy ensued after the removal of both ovaries for tumour or chronic inflammatory disease. (1) Schatz. Both ovaries removed for cystic tumour; one tube and a piece of ovarian tissue were purposely left behind. Five years later the patient gave birth to a child at term. (2) Stansbury Sutton (Pittsburg, U.S.). Both ovaries removed for cystic disease; right pedicle severed by canter, left by scissors. Patient twice pregnant afterwards. (3) Gordon (Portland, Maine, U.S.). Removed both tubes and ovaries for inflammatory disease; patient delivered of a child two years later. Other reported cases were doubtful. Mr. Doran observed that presence of ovarian tissue was essential in these cases. In his own case it was probably a detached area lying in the right ovarian ligament; the cyst itself was certainly enucleated entire. The author suspected that the Fallopian tube escaped ligature and removal altogether, the base of the tumour being enucleated from the posterior layer of the broad ligament. The condition after operation would then be as in Schatz's case, the tube remaining entire. It was not absolutely certain, however, that the tube was not included in the ligature and in part removed. This occurred in Stansbury Sutton's and Gordon's cases, and reference was made to a case where pregnancy occurred after Cæsarean section and ligature of both tubes with silkworm gut for "sterilisation" (Galabin-Horrocks). The ligature might either loosen or perhaps ulcerate through the tube, which managed to heal behind it without stricture of its canal. The tube might then resume its functions, even if reduced to a stump.

Mr. J. BLAND-SUTTON said that he thought it right to state that Mr. Doran was the first one to study the fate of the ligature after ovariectomy. He was specially interested in the subject of the sterilisation of the patient, and Mr. Doran had referred to his (Mr. Bland-Sutton's) former views on this question. This view was that ligature of the tubes in continuity was sufficient to ensure sterility; and he was led to it by a case in which he ligatured the tubes in this way many years ago, the patient having remained sterile to this day. He had another case, however, in which the same operation was performed on account of epilepsy, which became very severe during pregnancy. The patient became pregnant several times afterwards, and he was then led to alter his opinion, and to believe that it was necessary to tie the tube in two places and divide it between the ligatures, or, better

still, resect a portion of it. It was interesting to note that Hunter had written a paper on some experiments in sows; he found that they readily became pregnant after ligation of the uterine horns. The subject had been investigated by Fraenkel from both the human and the comparative standpoint. He came to the conclusion that the only way to ensure sterility was to resect a part of the tubes and then to cut away that part of the tube that ran in the uterine wall, and to sew the peritoneum over the stump. A ligature on the uterine end of the tube was capable of making its way into the uterine cavity, and on one occasion a patient brought him a ligature expelled in this way. From observations on a series of cases in which he opened the abdomen a second time after the lapse of years, he found that the loop of ligature on the ovarian artery nearly always remained unaltered, whilst the loop on the uterine end of the tube had nearly always disappeared, leaving a smooth rounded stump of the tube.

Dr. GALABIN said that he had seen two cases in which ligation of the tube in continuity failed to prevent conception. One had been done by Dr. John Shaw, and one by himself. In Shaw's case, on which he operated later, one ligature had cut through and both ends of the tube had become sealed. Pregnancy must have occurred through the other tube. He had known a case in which an ovarian tumour developed after a double ovariectomy; a piece of ovarian tissue must have been left behind. Jacobs, of Brussels, had recorded a case in which a double oophorectomy for fibroids was done in 1890; for three years after she had amenorrhoea, and then menstruation came back for a time. This happened again on several occasions, after which she married and became pregnant.

Mr. Butler-Smythe and Dr. Griffith joined in the discussion, and Mr. ALBAN DORAN replied.

THE OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

On Saturday, May 31st, the above Society met in the Anatomical Department of the Medical School of Trinity College, Dublin.

Professor URBAN PRITCHARD occupied the chair.

The SECRETARY submitted the following report:—"Gentlemen, your Committee appointed to consider the desirability of securing for the children of the poorer classes systematic detection and treatment of ear disease, and to report at an early date to the Society, having carefully considered the reports submitted and the experiences recorded at the special meeting held on April 14th, have arrived at the following conclusions:—(1) That there exists among the children of the poorer classes a very large amount of ear disease which is preventable and curable; (2) that it is not sufficiently recognised that ear disease in childhood tends to considerable loss of hearing, health, and life, that it militates against a child's education, and that later on the subjects of it are seriously hampered in their life's work and often incapacitated for the services of the State; (3) that ear disease in children is often not treated, partly owing to neglect, and partly to ignorance and to the belief in popular fallacies, and more especially to an inability on the part of parents and teachers to detect it; (4) that any scheme having for its object the security of children against the consequences of ear disease to be efficient must provide for thorough and systematic examination and treatment; (5) and, lastly, having regard to the national importance of the subject, we recommend that a memorial embodying this report be submitted to the President of the Committee of the Council on Education.—Signed, Urban Pritchard, President; Arthur H. Cheate, H. Macnaughton-Jones, W. Permewan; and W. Milligan and W. Jobson Horne, Hon. Secretaries."

Mr. STORY moved the following resolution:—"That the report of the Committee appointed on April 14th to draw up recommendations as to a compulsory examination of the hearing powers of school children be adopted, and that the Secretaries of the Society be instructed to carry out the recommendations contained in Clause 5 of the report." Dr. Woods seconded the motion and re-

marked that the frequency with which children were boxed on the ears had an injurious effect on their hearing powers; such a mode of punishment was calculated to bring on an abscess, and in one case of which he knew death resulted, consequent on brain trouble that set in afterwards. Would it be advisable to refer to the matter in that report?

The CHAIRMAN suggested that Dr. Woods should make out a report of that case, and send it to the Hon. Secretaries for the Committee.

The report was adopted unanimously.

Dr. Woods then communicated a case of

ABSCESS OF THE BRAIN, FOLLOWING MIDDLE EAR DISEASE. He had referred to this case some time ago in an address to the Ulster Medical Society. (This appears on page 620.)

Mr. CHEATE said he should like to have details from Dr. Woods regarding the treatment of the abscess, particularly with reference to drainage.

Dr. NELSON said in the year 1882 he had a case resembling that of Dr. Woods in many respects. In the operation performed he opened the antrum, then went a little up, made a perforation right through the skull and let out a large quantity of pus. He considered that the case was important from an historical point of view, as it was the first case on record in which the cranium had been perforated for the relief of an extra-dural abscess, also due to old-standing suppurative ear disease.

The CHAIRMAN asked if it had been a success.

Dr. NELSON said that they had been able to insure his life subsequently.

The CHAIRMAN said it would be very interesting if they could get the history of all the successful cases, and how the patients got on in after life, but unfortunately so many of these cases were lost sight of. He mentioned a case similar to these under discussion which came under his own observation some eight years ago. The abscess was opened exactly in the position that had been described. The patient got into that half-recovered condition which so many of them had noticed, and it was only some days after they had got the drainage-tube well into the substance that the man began to recover and then to rapidly recover. He was subject to epileptic fits afterwards, but these gradually passed off. He had them for about three years at intervals, and then became practically quite well and they lost sight of him.

Dr. Woods said that in the case of his patient the brain abscess was drained through a fairly large drainage-tube, perforated at the sides, and was dressed every day. He thought that on trying to change the tube for another the second tube did not go in as well as the one that had moulded itself to the opening. For that reason, he used the same tube every day, cutting off as much of it as was excluded by the gradual closing in of the abscess. The loss of substance was probably about half a cubic inch of the brain.

Dr. DEMPSEY then submitted a clinical case of

INTRANASAL GROWTH PERFORATING AND SPREADING OVER HARD PALATE.

The history of the case was the ordinary history of nasal obstruction nearly altogether confined to the left side. The patient was a boy, *æt.* 12. About four years ago it was noticed that his nose was becoming stuffed. The stoppage of the nose increased gradually until finally it became complete. This went on for a couple of years, and the patient noticed a growth arising from the palate of the mouth. On examination it was found that the left nostril was completely covered by a soft, pinkish growth which bled freely on being touched. On opening the mouth, the palate was seen to be covered almost entirely by a soft, pink, mushroom-like growth, evidently born of the original growth. The naso-pharynx appeared to be also completely occluded by a growth. On digital examination, however, the vault was found to be free. The diagnosis was that the case was probably one of fibro-sarcoma arising either from ethmoid or antrum Highmore. His object in bringing it there was to get some suggestion as to the best mode of treatment. It seemed a pity to send the boy back to die without doing something for him.

Dr. MILLIGAN said that Dr. Dempsey had been good enough to allow him to put his finger into the back of the boy's nose. In his opinion the vault was not free, and he thought that in all probability the growth sprang from the vasi-sphenoid and did not show any very malignant tendencies. As they all knew, these growths were of various degrees of malignancy. Having quoted a somewhat similar case, and referred to the mode of treatment, which brought about perfect recovery, Dr. Milligan said he was of the opinion that the growth could be completely drawn out by means of a snare after partial resection of the upper jaw, and then, with a long chisel, part of the vasi-sphenoid could be gouged away. It was worth while trying the operation. The boy appeared to be becoming slightly hectic, and he thought something ought to be tried very shortly.

Dr. JOHNSON HORNE thought the growth in that particular case started from the septum of the nose, and that there would be no difficulty in removing it. There was, of course, the danger of hæmorrhage, but he did not think that that would be very serious.

Dr. WOODS thought with the other speakers that this tumour should be removed. The boy ought to be given every chance, but he would hesitate to say whether the operation would be successful or not. He thought it would be enough to get away the active part of the growth, that part of the tumour which was the mother-part, so to speak. He considered complete removal of these tumours was out of the question.

The CHAIRMAN concurred in considering that the boy should be operated on; it was not at all clear where the origin of this tumour was. He thought that it came from the maxillary antrum. In a similar case, the patient died on the operating table, but as this operation was the only chance of saving life it ought to be attempted.

The SECRETARY read a communication from Dr. Macnaughton-Jones on

DOUBLE PERFORATION OF THE MEMBRANA TYMPANI, which appears under the heading of "Clinical Records." Dr. STORY showed a case of naso-pharyngeal growth. A man, first seen in August, 1897, came with a history of a nose stopped for some uncertain time, and bleeding from the throat for three or four months. The soft palate was seen to be pushed forward, and an ulcerated tumour projected into the pharynx behind. The tumour was removed by electric snare with very considerable difficulty in August, 1897, hæmorrhage having set in at the time. A recurrent growth was removed also by electric snare in January, 1898, with hardly any bleeding. Electric cautery was then applied for some weeks. Again, in December, 1898, a large piece was similarly snared. Dr. Earl's report on the tumour of 1898 stated that it varied in different places, portions being fibro-myxoma, other parts fibroma, rather cellular, others very cellular fibroma, and here and there a field which had all the appearance of spindle-celled sarcoma. Dr. Beatty's report on the tumours of 1900 contained the following:—"Chiefly fibrous tissue, in places vascular, large vessels everywhere, and in places practically cavernous. In one portion of the section the tissue consists of spindle-cells, but they are not arranged in the regular streams usual in sarcoma; and, as all the blood spaces have distinct walls, the tumour is probably non-malignant." Nothing had been seen of the patient since the beginning of 1900.

Dr. PERMEWAN was of the opinion that the method of removing tumours by means of a snare was not always satisfactory, and generally speaking he thought that the use of forceps was more advisable. That was the method he suggested in the present case. There was considerable growth on the right side of the nose, and he was not so sure that there was not as much on the other.

Mr. JONES mentioned a case somewhat similar to that of Dr. Story's. The patient was still under treatment, and he was afraid the tumours would have to be chiselled in some way.

Dr. WOODS said in cases where the tumour is attached to the place where it originally grew from, he did not

think that a better method could be adopted for removal than the electric snare, and explained the mode of procedure by which with a piece of platinum wire he was able to plough pieces of a tumour away, and in that way cure a patient. The difficulty in the way of that course was entirely a question of attachment. When secondary attachment had set in the operation was very difficult.

Professor CUNNINGHAM gave a most interesting and instructive lantern demonstration of the central connections of the cochlear nerve in the orang, chimpanzee, gibbon, and man.

Professor COFFEY, with an admirable series of lantern slides, then gave an interesting demonstration of nerve endings in the ventral cochlear nucleus, the superior olivary, and the trapezoid body.

The PRESIDENT demonstrated lantern slides of microscopic sections of the internal ear.

Mr. A. H. CHEATLE exhibited specimens to show the petro-squamosal sinus.

Dr. JOHNSON HORNE exhibited preparations demonstrating the formation of an abscess sac at the site of the saccus endolymphaticus.

It was announced that the next meeting would be held in London, and the proceedings terminated.

In the evening the visiting members were most hospitably entertained by their Dublin confreres, and the extra-metropolitan meeting of the Society was, both from the scientific as well as the social point of view, a most successful one.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF OBSTETRICS.

MEETING HELD AT THE ROYAL COLLEGE OF PHYSICIANS,
ON FRIDAY, MAY 23RD, 1902.

Dr. W. J. SMYLY in the Chair.

Dr. ALFRED SMITH exhibited two specimens of double pyosalpinx of tuberculous origin; the first, tubes removed from a patient, æt. 19, who suffered from amenorrhœa for one year previously; the second, tubes from a patient, æt. 35, who suffered from severe dysmenorrhœa, with profuse menstrual flow; the third, a large pyosalpinx removed from the left side from a married woman, who was anxious to become pregnant. In the last case, the right tube and ovary were apparently normal, the enlarged tube was intimately adherent and very tense. It was aspirated and cyst cavity washed out; contents, when received by Dr. Dargan, the pathologist, showed tuberculous deposits on surface of tubes with caseous degeneration; the cyst contents showed pure cultures of staphylococci. This is interesting, as there was no history of the invasion, and the right tube and ovary were normal. He also exhibited an extremely large fibromyoma attached to a fourth month pregnant uterus. It was removed from a patient, æt. 28, on account of the extreme distress caused by its rapid growth, and it was impossible to do a myomectomy. The distress was so pronounced that the patient could not lie in bed. The abdomen was so tender that it could only be prepared for operation under ether. A supra-vaginal operation was performed, recovery uneventful.

Dr. HORNE exhibited a uterus removed by vaginal hysterectomy. The patient was æt. 50, and mother of two children, last pregnancy nine years ago, menstruation remained regular until a year ago, ceased for three months, then became irregular. On examination the uterus was freely movable—normal position. There had been no watery discharge. Curettage of the uterus was performed to check the hæmorrhage. On examination of the scrapings by the pathologist, Dr. McWeeney, he reported:—"These are very succulent, richly cellular, and exhibit an adenomatous overgrowth of the uterine glands, which appear to be undergoing malignant change, is in fact partly converted into adenocarcinoma." On account of this report he had advised vaginal hysterectomy, which a few days later he performed. The operation presented no special difficulties. The convalescence was perfectly normal. The important points he

wished to call attention to was the absence of the usual symptoms associated with malignant disease, and the importance of having uterine scrapings carefully examined by the microscope in women near the climacteric when hæmorrhage is irregular.

Dr. E. HASTINGS TWEEDY then read his paper,

OBSERVATIONS ON THE FIRST STAGE OF LABOUR; THE CAUSAL RELATION OF THIS STAGE TO RUPTURE OF THE UTERUS.

The onset of labour should be reckoned from the moment of the establishment of uterine polarity. Uterine polarity is probably induced by an over-stretched condition of the lower uterine segment nerves, brought about as a result of labour contractions. A fully dilated os is not always of a diameter sufficient to permit of the passage of the fœtus. The condition known as rigid os, with its thin knife-like edge, is in reality an os that has reached its maximum degree of expansion. In primiparæ especially, an os in this state tears readily, but in the event of its not quickly doing so, it moves in a direction upward and backward in response to the more powerful pull exerted on it by the posterior uterine muscular fibres. In consequence of this, the anterior cervical lip becomes enormously elongated, and is erroneously spoken of as being incarcerated or nipped between the pubes and the presenting part of the fœtus. The liberation of the lip necessitates the tearing of the cervix. A lip such as this becomes rapidly œdematous, and often protrudes through the vulva at the completion of labour. Under these circumstances, the cervical tear, though extensive, cannot be dealt with by immediate suture, not alone because of the great œdema, but chiefly for the reason that there is never any posterior lip to which to stitch it. Occasionally the os does not tear after it has moved upward and backward. Then rupture of the lower uterine segment and of the anterior fornix of the vagina becomes probable. These structures will, under the conditions named, lie one on top of the other, and will be subjected to the counter-pulls of anterior and posterior uterine fibres. Ruptures such as these take place insidiously, the only symptom which marks their onset frequently being the moving of the rigid os upward and backward.

Dr. HOARE said that in his experience cases of ruptured uterus were usually associated with contracted pelvis, and were consequently unusual in Dublin, where the condition named was seldom met with. He did not look on the strong pains as the principal cause; he rather inclined to the idea that insufficient dilatation or dilatation slowly occurring was the chief factor, the head being shoved through, not being pressed through. The occurrence of the rupture on the left side was clearly due to the position of the woman on her left side during the labour.

Dr. PUREFOY said he would like to know if Dr. Tweedy considered that a rigid os was the normal condition in primiparæ; such an idea seemed to him to be novel and startling. He would also like to hear what Dr. Tweedy considered as full dilatation of the os. In his experience, he did not find the pulling up of the posterior lip to be a precursor of rupture. The number of cases of rupture occurring in practice is small, and in his opinion uterine rupture is not nearly so complicated with rupture of the vagina as Dr. Tweedy states (75 per cent.).

Dr. ALFRED SMITH said that he did not see much benefit from the new definition of Dr. Tweedy's. Polarity was hardly a practical term. The old definition of the beginning of labour was equal to all demands. He expected to have heard something of the type of pelvis, the rigidity of the os, and the character of the pains from Dr. Tweedy.

Dr. JELLETT said that he recognised that dilatation of the external os was not a sign of labour; he would be inclined to consider that dilatation of the internal os was. He did not accept Dr. Tweedy's explanation of polarity; he associates it more with some regulating nerve fibres connected with the higher nerve centres which regulate the muscular contractions, in a manner analogous to the simultaneous contractions of the fibres of the body and

relaxation of the sphincter of the bladder and the rectum. In his opinion the first stage of labour ends clinically with rupture of the membranes.

Dr. SMYLY said Dr. Tweedy's paper dealt with two subjects: the first stage of labour and rupture of the uterus. Much depends on where he considered the polarity begins; if he included the whole lower uterine segment the labour may be said to commence at the seventh month of pregnancy. He looks on Müller's ring as a very uncertain point from which to count. If the lower segment of the cervix is included it is equally faulty. Dr. Jellet's definition cannot be accepted, for rupture of the membranes has occasionally occurred months before labour. Why does the cervix rupture? He was not satisfied with the statement, "When it has reached the greatest possible amount of extension." He considered the rupture to be caused by want of a proportionate rate of dilatation of the os and the force of the expelling pains. The paper was of value as causing them to discuss a subject which is one of extreme interest.

Dr. HASTINGS TWEEDY, in replying, traversed the assumption that the os never tears in normal deliveries, so-called, and when the membranes have not prematurely ruptured. Such a view is contrary to conditions that obtain in other structures of the body as, for instance, the perineum, which will at times rupture, despite the gradual and prolonged efforts to dilate it. Elongation of the anterior cervical lip is a condition frequently encountered, and this, in his opinion, indicates that the os has ceased to respond to the forces which cause its expansion. As to the injection of cocaine into the edge of a rigid os and the supposed relaxation of the structure thereby being cited as proof of its origin in muscular spasm, he could conceive of nothing more far-fetched. Cocaine had no effect on motor nerves, and many reasons could be adduced to account for this supposed condition of relaxation more reasonable than the one given. He did not agree with Dr. Jellet that from a practical point of view rupture of the membranes may be taken as an indication of the commencement of the second stage, as from that time the danger of retarded delivery commenced. Such an assumption implies the complete draining away of the liquor amnii, which, of course, does not occur after rupture of membranes, save under abnormal conditions. He did not see that any analogy could properly be drawn between the bladder mechanism connected with urination and that of the uterus in the first stage of labour. The formation of the lower uterine segment during pregnancy causes considerable displacement of the vessels and nerves, as these have to course through this segment in order to reach the cervix. In consequence of this the relaxation of the os during the period of a labour contraction can be accounted for in a manner more simple than by inferring a special nerve centre which has so rarely to be called into existence.

THE GENERAL MEDICAL COUNCIL
OF
EDUCATION AND REGISTRATION.

SUMMER SESSION, 1902.

SIR WM. TURNER, F.R.S., PRESIDENT, IN THE CHAIR.

SEVENTH DAY.—TUESDAY, JUNE 3RD.

CONTRARY to expectations, the Session did not terminate on Monday last, several important items of business remaining over. Among them was the

REPORT OF THE PERSONATION COMMITTEE.

This was discussed by the Council in committee, when Mr. HORSLEY moved that all applications for restoration to the Register, or for registration under exceptional circumstances, should be accompanied by a statutory declaration in the terms set forth. This was passed (in committee), and on the Council resuming it was resolved that the Personation Committee be instructed to prepare for next Session a complete report on the whole subject.

THE DIPLOMA IN PUBLIC HEALTH.

Dr. McALISTER brought up the printed resolutions and rules as amended for adoption. Rule 4 requires candidates to produce evidence that, after obtaining a registrable qualification they have attended the practice of a hospital for the treatment of infectious diseases. Dr. NORMAN MOORE pointed out that this rule, if enforced, would virtually prevent candidates from studying for the diplomas in London, since it had not been found possible to obtain the necessary facilities. He therefore moved that "the study of the methods of administration shall include the methods of dealing with patients at their admission and discharge, as well as in the wards of a hospital."

Dr. McVAIL did not see why health diplomas all over the country should be vitiated because London had no facilities for studying the subject. After some remarks by Sir CHRISTOPHER NIXON, the amendment was modified to read as follows: "The methods of administration shall include the methods of dealing with patients at their admission and discharge as well as in the wards and the medical superintendence of the hospital." This was agreed to.

Dr. McVAIL protested against the Council's decision of two years ago being upset by fifteen members, and he moved that the amendment just passed should be referred back to the Public Health Committee for consideration and report, but this was negatived by fourteen to seven.

The Report of the Education Committee on

PRELIMINARY EXAMINATIONS IN SCOTLAND

was received, and the Chairman of that committee (Sir John Tuke) having asked what course he ought to take in regard to the reply to be sent to the British Medical Association it was decided to leave it to the Education Committee to do what they thought best in the matter.

THE MIDWIVES BILL.

On the report of the Midwives Committee being brought up for adoption, Dr. McALISTER entered an energetic protest against its adoption, he having been unable to attend the meeting of the Committee at which the report was drawn up.

The motion that the Council approve the report with the exception of one paragraph having been negatived, Mr. G. BROWN moved "That in the opinion of the Council the Midwives Bill, as amended by the House of Commons Grand Committee on Law, does not contain the safeguards necessary to protect the public against the practice of midwifery by ignorant and incompetent persons." This, after some discussion, was carried by thirteen to five.

This practically terminated the work of the Session, and, after the usual vote of thanks to the President, the proceedings came to an end.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, June 7th, 1902.

At the Medical Society Hr. Menzer took for his subject

THE SERUM THERAPEUTICS OF ARTICULAR RHEUMATISM.

Following the suggestion of Pavel, the speaker had procured a supply of virulent streptococcus cultures, from which he had prepared an antistreptococcus serum, with which he had made experiments in thirty cases of articular rheumatism of the human subject. He proceeded on the assumption that acute rheumatism indicated an increase of streptococcus angina, the highest expression of which was a general streptococcus infection. The disease of the joints, as well as the frequent inflammation of serous surfaces, were not to be looked upon as the action of a specific infection, but as a peculiar form of

reaction of the system. The cocci passing from the tonsils into the blood do not circulate long therein, but become deposited in the joints, the pericardium, &c. The participation of joints lying far apart from each other did not depend on the passage of cocci, from one joint to the other, but from the reaction of the joints.

Streptococci from the tonsils were agglutinated in the serum used by the speaker.

In order to prove the specific action of the serum first of all, normal serum was injected in two cases of chronic articular rheumatism and then Marmorek's antistreptococcus serum. Then he injected his own serum and this was followed by fever and swelling of the joints affected.

He then went on to the therapeutic use of his serum and first tried to cut short the disease. This was not successful, although he made use of doses of 55 cm., which never did any permanent mischief. On the other hand, endocarditis appeared to be favourably influenced and re'apses of the disease avoided.

As regarded the effect in the different forms of the disease, acute, subacute, and chronic, nothing striking was observed that was not otherwise observed in the various forms of the disease.

Chronic cases reacted better and improved when massage and hydro-therapeutics were also employed. In very bad cases of long standing the serum failed.

In other diseases in which streptococcus infection played a part, such as nephritis after scarlatina, acute bronchitis, and mixed infective phthisis, a transient exacerbation of symptoms was set up, which the author believed to be due to specific reaction.

As regarded permanent results of the treatment, he could not say much, but he thought his attempts were worth following out and verifying, and believed that he had found in the serum a means by the aid of which our attempts at successful treatment would be reinforced.

Hr. Senator, in whose clinic these investigations had been carried out, had at first been very mistrustful, as he did not quite accept the theoretical deductions. He had been, however, surprised by results, even in cases that had been treated unsuccessfully with salicine and similar agents. It was to be remembered, however, that articular rheumatism was extraordinarily changeable in appearance, and that a prognosis could never be given with certainty at any given moment. The results were therefore to be accepted with great caution, but at any rate they were worthy of following out.

Hr. Aronsohn had for five years been engaged on the preparation of an antistreptococcus serum, and was of opinion that all streptococci did not belong to the same category. No experiments on animals could be relied on until they had been tested on the human subject. The reaction spoken of by Menzer was due to the retention of poison in the serum, which in his experience was never destroyed until after the lapse of at least four weeks. The clinical observation brought forward proved nothing.

Hr. Meyer also took the view that there were different kinds of streptococci. The serum prepared by himself only protected it against certain streptococcus infection, not against all. He asked why if articular rheumatism was a common streptococcus infection, Marmorek's serum should be absolutely useless?

Hr. A. Baginsky was also a believer in multiple kinds of streptococcus. He warned them against looking

upon injections of serum as harmless, and introducing it into private practice at present. He had seen four cases in which very threatening symptoms followed the use of it.

Hr. Menzer, in reply, said he had never seen injurious consequences following injection. The varying activity of known anti-streptococcus serum was due to the varying toxins in the different cases, and not to a multiplicity of kinds of streptococcus. His clinical experience was in favour of this method of treatment.

At the Free Society of Surgeons, Hr. Bouchert spoke on the

INDICATIONS FOR LITHOTOMY AS OPPOSED TO LITHOTRIPSY.

Lithotripsy was in general to be preferred, but it had its limits. The stone must not be too hard, nor so large as to nearly fill the bladder. Changes in the urinary canal would also influence the choice of operation. Cystitis was also an indication for lithotomy, as also a very sensitive bladder or diverticula in it. Enlargement of the prostate was on the whole not a contra-indication, but there were two forms in which it was, viz., when along with the hypertrophy there was concentric hypertrophy of the bladder wall, whereby the lumen of the bladder orifice was materially affected, and when the middle lobe of the prostate was specially affected. In cases of already existing pyelitis and the simple introduction of the catheter set up fever, &c., lithotripsy was out of the question.

He would shortly sum up. Generally in cases of calculus lithotripsy was the operation to be preferred, but there were certain exceptional conditions in which lithotomy was demanded.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, June 7th, 1902.

LEUCOCYTHÆMIA LYMPHATICA.

LANG exhibited to the "Gesellschaft der Aerzte" a man who had first consulted him with reference to an intense itching of the skin, which was covered with a number of pigmentary spots of size ranging from a pin's point to that of a millet seed. Under the skin, particularly that of the sides of the chest, hard nodules could be felt. Later, temporary or transient attacks of urticaria occurred, leaving large vesicles behind it. The lymphatics, tonsils, spleen and liver were all greatly enlarged, and the sternum was sensitive to the touch. A large number of mononuclear leucocytes were present in the blood, and measured with Fleischl's hæmometer the hæmoglobin was 40 per cent. After a short administration of arsenic all the glands diminished in size.

Lang showed another patient, a woman, who had suffered for the last twenty years from a progressive idiopathic atrophy of the skin of the lower extremities extending upwards to the buttocks. There was no stiffness or difficulty in moving the joints.

INTRAVENOUS OXYGEN INJECTION.

Gärtner gave the members a physiological description of this element as used in the laboratory. Dogs, he said, can bear the injection of a large quantity of pure oxygen into the veins, even for an hour at a time, without any apparent injury or inconvenience to the animal. It will be found in the blood circulation up to the right ven-

tricle and on to the capillaries of the lung, but after that the gas is absent, and probably none ever reaches the left ventricle. When a large quantity is injected a splashing or cooing sound may be heard at the heart, even when standing at a distance.

At the beginning of the operation the vagus pulse is observed, which is considered by operators to be a reflex action arising from the sudden irritation of the endocardium. The breathing is deeper and the blood pressure changed.

When the operation is commenced vigorously with large quantities of the gas rather alarming phenomena present themselves which are supposed to be due to a choking of the pulmonary capillaries; these dangerous symptoms soon disappear, however, after a slight pause in the administration of the gas.

On opening the right ventricle the blood is found to have a bright red colour bubbling with a fine effervescence of gas; the right ventricle is not increased by using 20 c.c. per minute. On dividing the vagus, thus slowing the respiration, the blood pressure is not increased, because the irritation of the venous blood on the vasomotor constrictors is abrogated. Death of the animal usually ensues from a retention of the effete gas CO_2 ; if a solution of caustic soda be used to absorb the CO_2 , the animal will live fifty minutes longer without any further administration of oxygen. In the case of CO poisoning the administration of oxygenated water or injection of oxygen gas will restore the pulmonary and cardiac movements in a few minutes.

These favourable results in animals suggest that it may be worth while to try this treatment in some of our more intractable, dangerous diseases where suffocation is imminent, such as foreign bodies in the trachea, laryngeal croup, in cases of severe pneumonia and carbon monoxide poisoning, or in the asphyxia of the newly-born from pressure on the umbilical vein.

It is not necessary in every case to inject large quantities of oxygen. Arterial blood contains 20 per cent. by volume of oxygen, while the venous contains only 7 per cent., leaving 13 per cent. to be added to the venous to equalise. It is found by experiment that a 3 per cent. solution gives rise to no irritation of the vessels and heart and is easily absorbed by the organism. The best measure of quantity is afforded by the splashing in the ventricles; when this is heard the quantity should be reduced. It is needless to add that absolutely pure oxygen should be used, as the commercial article sold under that name may contain as much as 20 per cent. of nitrogen.

ANEURYSM OF RIGHT CAROTID ARTERY.

Kaufmann showed to the Medical Society a man, æt. 50, who acquired a chancre in 1885, and who commenced to experience difficulty of breathing with palpitation two years ago. In October last year a swelling about the size of an almond was noticed on the right side of the neck, which rapidly increased in size till swallowing became difficult. Distinct pulsation could be found in the front of the swelling down to the sternum, which was diagnosed as aneurysm of the left carotid. The apex beat was in the sixth intercostal space, slightly within the axillary line, strong and heaving. The cardiac area of dulness was increased. The Röntgen rays showed a large pulsating mass about the size of a child's head.

Compression was applied; the patient can now swallow with comparative ease, breathing easy, pulsations soft and regular, and tumour small.

HYPERTRICHOSIS.

Ehrman brought forward a young woman whom he had operated with the Röntgen rays for hypertrichosis. After the treatment large blisters rose corresponding to the areas unprotected by the tinfoil which subsequently gave rise to multiple hemangioma. Such facts prove that the Röntgen rays do not start an elective action on particular cells, such as the fine papillæ of the hair follicle, but also act on other structures, such as nerves, vessels and fibrous tissues, the structure whereof is ultimately altered.

Teleky related the history of two cases which agreed with Ehrman's opinion. In both of them a condition of teleangiectasia set in. There is no doubt about the removal of the hairs, which may be effected in two ways, either by short, repeated applications of the rays, or by a few prolonged sittings. The first method appears to be the safer and less inconvenient of the two.

Spiegler thought these adverse symptoms, teleangiectasia, &c., were due to long and severe application of the rays, as he has seen it in only one case after a year's treatment with the rays.

Continental Health-Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

AIX-LES-BAINS.

THOSE who knew Aix-les-Bains in 'past' years, and after an interval of several seasons come here again today, cannot but compliment the managers and the Municipality of this charming Savoy Spa on the progress visible all round. The now well-kept Park, the beautified Place des Bains, elegant Casino Theatre, cleanly streets, new and enlarged hotels; on every side progress. Naturally there is yet room for more progress. Unexcelled in beauty of situation and in value of waters no improvement should be left unmade to keep Aix at the head of French health-resorts. Even then some of its visitors would not be satisfied!

Sitting near the door of its handsome Thermal Establishment, I overheard some cosmopolitans disparaging Aix. One good Dutch doctor complained that it could not compare with Broeck, "the original spotless town" of Holland. To the amusement of his audience he advocated the adoption by the *Aixoïis* of regulations somewhat similar to those of Broeck:—

"Citizens must leave their shoes at the door when entering a house.

' Before or after sunset no one is allowed to smoke excepting with a pipe having a cover, so that the ashes will not be scattered upon the street.

"Anyone crossing the village on horseback must get out of the saddle and lead the horse.

"A cuspidor shall be kept by the front door of each house, where it may be accessible from the window.

"It is forbidden to cross the village in a carriage or to drive animals through the streets."

Just then he was interrupted by an American automobile noisily passing and raising dust; which led to another advocate of progress urging the more immediate advisability of Aix adopting (in advance of other

Summer Stations) some precautions like those contemplated in the Riviera; such as sprinkling streets and roads with mixtures of paraffin, diluted tar, and similar glutinous products; or if the smells therefrom were objectionable in a pleasure-resort, to follow THE MEDICAL PRESS AND CIRCULAR's prescription of tar-water, as "costless and acceptable in odour." (This subject is evidently awakening interest among business people and visitors throughout the Riviera, many roads of which during the past season were rendered by the constant streams of automobiles (as a Paris journal said) "unpleasant even to healthy passengers and almost impossible to invalids."

Progress at Aix-les-Bains is also apparent in the Thermal Establishment; the humane additions to the Berthollet Department, the improved pulverisations, and the new *Bains de Luxe* being evidently appreciated. The chief glory of the Aix treatment, however, is, as hitherto, its unequalled

DOUCHE-MASSAGE.

Massage, as distinguished from friction merely, is considered to have been introduced at Aix on the return of Napoleon Bonaparte's army from Egypt. Dr. Daquin, of Chambery, in writing of the Aix waters, in 1808, suggests that *masement*, as used in the Egyptian baths, might be advantageously practised after the Thermal Baths or Douches at Aix, and (in his pamphlet on "The Thermal Treatment of Aix-les-Bains") Dr. Forestier quotes from Dr. Despine's "*Observations de Médecine Pratique aux Eaux d'Aix*," published in 1838, the statement that: "Since the Renaissance of our Thermes in 1816, we bath, and we douche . . . we scrub, we *masse*, we *stew*." From these remarks of Dr. Daquin and Dr. Despine Aix claims the earliest application of massage in any European country; but Dr. Forestier acknowledges that if first practised at Aix, massage was "more scientifically studied later on in Sweden, in 1830, by Ling." It was Dr. Forestier who, happily, gave the name *Douche-massage* to the present method of *douche* combined with *massage*, or in other words, "*massage under the douche*." And to the same gentleman (the third of the name, grandfather, father and son, in successive practice as physicians in Aix), Aix owes the invention in 1889 of the inclined board, which has been since copied or varied at other spas.

The imitating or adoption of the Aix *douche-massage* in various places and countries (as at Bath, Harrogate,

Vichy, Virgina Hot Springs, &c.), is a testimony to its efficacy; but it is claimed by the Aix physicians that nowhere can it be so effectually employed as at Aix itself. In his recent publication, "The Gouty at Aix-les-

Bains," Dr. Blanc (who has been the longest in practice here of all physicians at Aix) briefly and pointedly gives three valid reasons for this claim:—

1. Water in large quantity with constant average temperature of 114° Fahr.

2. Softness of the Aix water combined with the *Baregine* (the curious organic matter peculiar to the Aix sulphur water) which facilitates the massage.

3. Instruction of the *doucheurs masseurs*, whose reputation has for a long time been well-established.

The Operating Theatres.

GUY'S HOSPITAL.

OPERATION FOR TRAUMATIC STRICTURE OF THE URETHRA.—MR. ARBUTHNOT LANE operated on a man, æt. about 50, who had suffered for a considerable time from traumatic stricture of the bulbous urethra into which it was impossible to pass any sort of instrument. Some time before an external urethrotomy had been performed with only temporary benefit. At the present operation the stricture was freely exposed from the outside, when it was found to be very limited, involving less than a quarter of an inch of the urethra. The entire stricture was excised and the edges of the urethra brought together by sutures. The result of the operation was most satisfactory, and the patient left the hospital with a normal urethra. Mr. Lane referred to a method for the treatment of strictures which he considered to be quite new, and which he had found of great service. The principle involved consists, he said, in the exposure of the strictured area through a perineal incision, and by the careful division of the cicatricial tissue along the length of the stricture, the urethra itself not being opened. After this is done an instrument of considerable size can be passed readily through the stricture. In this way Mr. Lane thought the stricture can be treated much more effectively than is possible by any method of external or internal urethrotomy now in use, and with very much less risk, since the perineal wound is sterile and can be closed at once; while the division of the cicatricial tissue form-

ing the stricture can be effected more completely than in any other way. This method could not, of course, be applied to the case just operated on, since in it the stricture resulted from a complete rupture of the urethra, and not from the contraction of any inflammatory material about it. Fortunately the stricture was so placed that the edges of the fore-shortened urethra could be readily brought together owing to the parts being freely mobile.

OPERATION FOR DIVIDED ULNAR NERVE.—The same surgeon operated on a woman, æt. 40, who had cut through her ulnar nerve immediately above the level of the annular ligament in pushing her hand through a pane of glass. At the end of six months there was no evidence of any repair, while the ulceration of the paralysed fingers was becoming an increasing nuisance. The ends of the nerve were exposed, and were found to be bulbous and separated from one another by an interval; these bulbs were freed and then divided vertically into eight segments; the ends of the nerve were then brought together, the digitations of each being fastened between those of the other so that the sixteen digitations were in accurate co-aptation. The external wound was then closed. Mr. Lane said he was led to adopt this method from an experiment which he performed with success upon another patient; the case he referred to was that of a woman who had complete ulnar paralysis for many months following a blow upon the ulnar nerve behind the internal condyle; the nerve was exposed in this situation, when it was found that its size diminished abruptly at this point and that it passed down in this condition to its distribution. By means of a very sharp small knife Mr. Lane made incisions through the normal and atrophied portions of the nerve in their length, dividing it in this manner into six separate slips; he hoped that into the material that would form between these segments the axis cylinders would extend from above. The result of this case was most satisfactory, the paralysis rapidly disappearing. When last seen the improvement was very great indeed, while the hand was very useful.

Death Under Anæsthesia.

A YOUNG woman died at the Great Northern Central Hospital last week while under the influence of an anæsthetic (A.C.E. mixture), just after an operation. A verdict of death from misadventure was returned.

The Coombe Hospital.

THE annual meeting of the Coombe Lying-in Hospital was held last week under the presidency of the Lord Mayor. The Registrar (Mr. F. Heney) read the annual report, which stated that the patients attending in the gynaecological department showed a marked increase, and among these were a number of most important and successful operations. The number of students attending the hospital showed a decided increase. The new buildings in Brabazon Street were nearing completion, and this new wing when completed would give increased accommodation by providing a thoroughly modern operating theatre, with sterilising and anæsthetic rooms, also two new wards for gynaecological cases, with extra accommodation for the staff. During the year the total admissions to the hospital were 747; extern maternity department attended at their own homes 1,648 cases; attended at special dispensary, 1,862; at general dispensary, 10,059. Total cases attended, 14,316. The Master, Dr. Thomas G. Stevens, moved that the report be adopted and circulated. This was seconded by Alderman Cotton and passed, and after the transaction of the remaining business the proceedings terminated.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion, 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 11, 1902.

THE GENERAL MEDICAL COUNCIL AND THE STANDARD OF PRELIMINARY EDUCATION.

It is a satisfactory sign of the times that outside pressure is being brought to bear on the General Medical Council to fulfil the promises made in the past in respect of an improvement in the standard of preliminary examination for medical students. In 1898 the attitude of the Council really appeared favourable to a change which had long been demanded by the profession in general, but at the last moment it was thought desirable to obtain the advice of certain experts in educational matters, and these gentlemen, in somewhat ambiguous terms, turned the scale against any raising of the standard. The feeling which was excited by the action of the Council ostensibly based on this pronouncement was very ably expressed by the delegates who waited on the Council last week from the British Medical Association. The speakers did but voice the prevailing opinion when they urged that those who aspire to enter a learned profession should be called upon to afford evidence of culture rather above than below that of the general public. The subject is one which has been discussed over and over again by the Council with ludicrously inadequate results; indeed, it is difficult to point to any results worth speaking of. Those who have not followed the debates of the Council may well ask on what conceivable ground the Council has held its hand and has abstained from doing that which it had formally declared to be an important and urgent matter? The answer is that by raising the standard of preliminary education a large number of intending students would be thereby debarred, thus "unduly depleting the ranks of the profession." This is a pure, nay an unwarrantable, assumption, but were it even so, the excuse

is one which should make us blush for the backward state of our system of education. The last reason alleged for not taking action is that the whole question of secondary education is at present under discussion in Parliament, but the feeling of the profession, or at any rate of that section of the profession which has expressed any opinion at all, is that the standard should be fixed without waiting for the secondary education of the country to be brought up to a theoretical level not as yet ascertained. It has over and over again been urged upon the Council that the profession ought to control its own portals, and at one time there even appeared to be a chance that the Council might take the reins into its own hands, and organise a preliminary examination of its own to be passed by every intending medical student. Unfortunately this prospect was frustrated, and the energies of the Council have been frittered away in sterile discussion. It is worthy of note that during the last twenty years the proportion of students who voluntarily take the higher, in preference to the lower, standards has increased from 20 to 50 per cent., but there remains nevertheless too large a residuum of badly-educated men in the profession and too large a proportion of badly-educated aspirants who obtain admission through the lower grades of examinations. Incidentally it may be found desirable to fix a somewhat higher minimum age for entrance upon medical study. The Council fixed sixteen, which is certainly too young, and the age of seventeen suggested by the delegates, if anything, errs on the side of youth. The Council declared some years since its desire to arrange for a single preliminary examining body, but little or nothing has been done to carry this pious intention into execution. That the standard of preliminary education is too low is, as one speaker observed, not an impression but a conviction. The delegation was courteously received and was promised a carefully reasoned reply to the report which they presented to the Council. We wish we were able to feel that something was likely to result from the interview, but past experience of the Council in this matter has been so discouraging that we can but hope.

PLAGUE PREVENTION.

THE possibility of preventing the spread of plague, judging from recent experiences in the United Kingdom, may now be regarded as an established fact. Notwithstanding that this most insidious infection has been introduced time after time into various British ports during the past few years it has in no case been able to secure a foothold. Side by side with former experiences this comparative immunity presents a contrast sufficiently striking to merit the consideration of all concerned in the advances of practical prevention. The facts of the modern attitude with regard to plague all hinge upon the view published so long ago as 1894 by Professor Koch to the effect that plague was primarily a disease of rats, and only

human in a secondary degree. That opinion has since attained the position of an established principle but its practical deductions have not yet been adopted and put into force with that unreserved and stringent thoroughness which is essential to the proper application of sanitary preventive laws. In how many great ports of Europe, for instance, is the precaution taken of insisting that all merchant vessels shall be rat-free both on entry and departure? Yet by the stringent and universal experiment of that one measure it may be safely assumed that plague might be henceforth confined to the eastern countries of its origin, where, indeed, the disease must be regarded as endemic in its prevalence. The great lesson to be learnt from modern science with regard to this scourge of mankind is the necessity for international action. Unless this preventive measure be adopted in all countries that have sea-ports, the danger of the reintroduction of plague will always be present. Meanwhile it is in the power of the individual country to destroy the rats in its own sea-ports and granaries and to insist that all ships entering its ports should be rat-free. The experiences of Bristol in that direction are encouraging, thanks to the enlightened policy adopted by the Port Sanitary Authority at the instance of their medical officer of health, Dr. D. S. Davies. In his recently issued annual report the whole subject of the rat introduction of plague is dealt with in a most interesting manner. In olden days Bristol suffered severely from the malady in question, and in the light of our present information the outbreaks were due to its position as a great trading port. The tonnage for 1901 amounted to 919,278 tons, and the total grain imports were 3,562,666 quarters. The difficulty of excluding plague under these circumstances would, indeed, be great were the disease widely prevalent in the grain-producing countries. So far as Bristol was concerned the rats on one ship were found, on bacteriological examination, to be infected with plague. The vessel was at once fumigated with sulphur, the rats destroyed, and all the men known to have had any connection with unloading the cargo were kept under medical supervision. This prompt and energetic action succeeded in warding off the danger altogether, for not a single case resulted. It is interesting to speculate as to what might have happened had the port watchman failed to notice or to report the six dead rats that were laying dead in the forehold of the steamer *Rembrandt*, when she lay alongside the quay ready to discharge her cargo of Smyrna grain into one of the largest grain warehouses in the city. Sooner or later the systematic destruction of rats on board ship must be rendered compulsory. As Dr. Davies points out, the supervision of infected persons and articles must, of course, be maintained on ordinary lines of intelligent control, but there is not one tithe of the danger involved in the arrival of a plague patient at a non-infected country that there is in the arrival of a vessel with infected rats in the hold. Altogether, the prevention of plague by rat-extermination is one

of the most brilliant chapters in the history of preventive science.

TUBERCULOSIS—THE SEED AND THE SOIL.

FOR too long a restricted view has been taken by many respecting the nature of tuberculosis. Koch's brilliant discovery focussed attention on the tuberculous seed. The accumulated experience of clinicians regarding the nature of the soil has been kept in the background. Bacteriologists have done much to place the study and control of infectious diseases on a scientific and common-sense basis. But the fact that many of our pathologists are devoid of all clinical experience and lacking in those interests and instincts which go to make the highest type of physician, has undoubtedly led to an incomplete presentation of the case respecting the character of consumption. The sway of the pathologist has for some years past been dominant, and although incalculable good has been accomplished by the recognition of bacteriological truths, the time it would appear has now come when the dogmatic and self-assertive attitude of many who are mainly interested in the academic aspects of tuberculosis should be met by clearly defined statements based upon clinical experience of the human subject. The investigations of the laboratory and the results of experiments on animals have to some extent encouraged a neglect of careful clinical observation at the bed-side, and the registration of the results of close observation of the human patient. It is a sign of immense significance that within the last few months important statements have been made by several leading clinicians of wide experience on the necessity for remembering that, in the protection of the subject from invasion by the tubercle bacillus and in securing arrest of the tuberculous process, the question of the soil is as important and in many instances, even of greater moment, than the influence of the tuberculous seed. We need only remind our readers of the recent pronouncements of Sir Dyce Duckworth, Dr. Frederick Roberts, and Dr. Howship Dickinson to indicate that a healthy reaction is occurring against the extreme view of many pathologists. The same subject was ably dealt with by Dr. Stephen Mackenzie in his recent oration to the Medical Society; and it may be safely concluded that the profession generally will welcome these much-needed warning voices. If the medical profession is to maintain its proper attitude in guiding public opinion in health matters, and especially at the present time in relation to the arrest of consumption, it must dissociate itself from the limited view and often alarming pronouncements of those whose zeal for pathology outruns their knowledge of clinical facts. In the in many ways most admirable prize essay by Dr. Knopf, which has been translated into some five different languages, we find the following:—"We desire to emphasise the fact that the chance for a cure of the consumptive individual does not at all depend upon whether he has a hereditary

tendency or has accidentally acquired the disease." This is but one example of those erroneous statements which might be taken from numerous recent publications arising from a restricted view of the subject, or the outcome of a warped judgment. We have learnt much since the tubercle bacillus was discovered. Many closed doors have been unlocked by the recognition of the specific irritant. But much work still remains to be done if the conditions of soil are to be made clear. The reactive properties of the various human tissues to the tubercle bacillus must be studied with greater care and more painstaking insight. Certainly the most hopeful methods of treatment are likely to be those which are based upon sound knowledge of the soil rather than fantastic ideas as to the vagaries of the seed.

Notes on Current Topics.

The Arthritic Factor in Medicine.

IT is now many years since Mr. Jonathan Hutchinson impressed upon the medical profession the importance of the arthritic diathesis. The term in question may be taken as a convenient expression for the inherited tendency in certain individuals to develop chronic diseases of the joints. Whether that result be due to an intrinsic weakness of the articular structures, or to some general dyscrasia of the blood or other constituents of the body, has not been determined. It is certain, however, that the offspring of tuberculous families often display the arthritic tendency in the shape of rheumatoid changes. The difficulty of establishing general rules with regard to arthritic tendencies is largely due to the fact that in the later stages of joint affections the specific characters are often lost. Thus it would be impossible in most cases to determine from mere inspection of a given joint whether its advanced destructive changes were originally due to, say, chronic rheumatism, osteo-arthritis, or Charcot's disease. It may be, perhaps, permissible to assume that the arthritic vulnerability has been inherited, while the specific exciting cause, *e.g.*, rheumatism or tubercle, has been acquired by the individual. In any case the recognition of the arthritic tendency has an important practical bearing on practical medicine, especially in dealing with the early days of joint trouble, when any hint of the exact etiological factor at work is of the greatest importance to the future welfare of the patient.

The Medical Benevolent Fund Society of Ireland.

WE wish to draw the earnest attention of all the members of the medical profession in Ireland to the report of the Medical Benevolent Fund, which appears elsewhere. The report of the honorary treasurer shows that while £1,330 were given away in grants during the course of the year, only £470 was paid into the Society's funds in the form of contributions. Further, of this £470, a net contribution of £157 came from co. Antrim, where Dr.

Richard Purdon is treasurer. This is not as it should be. The sole objects of the Society are "to assist a professional brother when in distress, or his widow and orphans after his death," and consequently its interests should appeal to every medical man. We cannot but think that the Society is a little responsible for the lack of general support which it is unfortunately experiencing. We doubt greatly if the average medical practitioner through the country is familiar with the fund and its objects. But even if they are familiar, that is not sufficient; they should also be familiar with the face or the handwriting of the Society's collector or treasurer. There is no charitable society which can maintain its good works by merely acting as a passive receptacle for, and dispenser of, funds. It must also be an active collector of them; indeed, in some cases, to succeed, it must be "a persistent beggar." The report states that in one or two counties almost every member of the profession subscribes, while in others only three or four subscribe. We venture to say that in the former case every member of the profession is asked, and in the latter case perhaps five or six are asked. Some day, when the Society asks every medical man to subscribe, they will get a satisfactory response. In the meantime, our subscribers cannot say that they are in ignorance of the fund and its objects.

Metropolitan Asylums Board Accommodation.

THE difficulties experienced by the Metropolitan Asylums Board in providing adequate hospital accommodation for infectious disease in London is reproduced in varying degree in all parts of the United Kingdom. In the metropolis, since the year 1890, the first complete year in which compulsory notification was in force, the proportion of admissions to the total number of legally admissible cases has increased year by year, with one exception, from 33.59 per cent. in 1890 to 70.63 in 1900. In the year 1900 35,247 cases of infectious disease were notified, and of 30,243 legally admissible to the managers' hospitals, 21,361 were actually admitted. The remainder was made up chiefly of 237 cases of puerperal fever and the rest erysipelas. Of the admissible diseases the greatest increase in the percentage of admissions to notifications has taken place in scarlet fever and diphtheria, while enteric fever comes next with a considerable interval. The percentage admissions for scarlet fever rose from 42.82 in 1890 to 75.15 in 1900, and those for diphtheria from 17.87 in 1890 to 72.48 in 1900, while those for enteric fever registered 22.49 in 1890 and 47.70 in 1900. The increase of hospital isolation thus provided must have prevented the spread of a vast amount of infection, but the considerable margin left over and above shows that the preventive system is far from having reached the ideal standard of universal adoption. It further proves the popularity of the Board hospitals with the public and affords a most hopeful encouragement for future progress. The accommodation of the Asylums Board is not

yet at all adequate and would be seriously strained by any recurrence of the great epidemic waves of scarlet fever or erysipelas. This necessity of progressive extension of hospital organisation, indeed, constitutes the great rock ahead of the Board.

The Polyclinic Dinner.

THE festival dinner of the Polyclinic and Medical Graduates College, which took place at the Criterion on Thursday evening last, was a great success, a very large number of distinguished medical and other guests assembling to further the cause of this excellent institution. Mr. Asquith, M.P., who occupied the chair, made a very eloquent appeal for public support. He pointed out that its consultation classes filled a gap in the philanthropic machinery of the metropolis, in that persons unable to pay ordinary fees, yet unwilling to have recourse to hospitals, could there have the benefit of the highest skill. Its principal claim to support, however, was, he said, that it sought to place one branch of education in this country on a level with that of other countries, and, he added, there was no profession or calling in which it was more important that facilities should be afforded for after, *i.e.*, post graduate, education. Theology might be stationary, law might wind in vicious circles, but medicine must of necessity keep itself abreast of advancing knowledge. He pointed to the extraordinary progress of the last twenty years in regard to such diseases as tuberculosis and malaria, and expressed the hope that a similar voyage of discovery would be made in regard to that most terrible and most inscrutable scourge of humanity, cancer. This result could only be attained by combined research and co-operation, and when funds had been provided sufficient to allow of the proper evolution of this institution, which, so far, was still in an embryonic stage, it would unquestionably form an admirable theatre for post-graduate research. He hoped the result of their meeting would be to engender further interest in the prosecution of this great work, which he believed to be no less advantageous and important to the profession than it was likely to be useful and beneficent to the people of this country. Some excellent speeches followed by Mr. Jonathan Hutchinson, Sir John Cockburn, and Sir James Crichton Browne, and donations amounting to upwards of £500 were announced by the treasurer, Dr. Theodore Williams.

Aliens and the Death-rate.

IT has generally been assumed that the miserable plight of the numerous aliens who take refuge in the Metropolis plays a part in the high death-rate which obtains in many quarters inhabited by them. The evidence of Dr. Shirley Murphy, the Medical Officer of Health for London, curiously enough, points in quite the opposite direction. In certain districts—St. George's-in-the-East, Whitechapel, Limehouse, and Stepney, for instance—the proportion of foreigners has risen during the last ten years to a very large extent (16 to 28, 24 to 31, 5 to 11) yet the death-rate has fallen in

each of these districts, while the birth-rate has risen. Dr. Shirley inclines to the opinion that the effect of foreign immigration, if any, is in the direction of lessening the death-rate from all causes, and he attributes this result to the greater care that these foreigners take of their health, in spite of their unfavourable surroundings, more particularly in respect of their sobriety. They take more care of their children and live more regular lives than the corresponding class of the British population. They would doubtless do even better were it in their power to avoid overcrowding, but this is a circumstance largely beyond their control. This is a lesson worth bearing in mind when the question of alien immigration is being discussed. Our own experience coincides with that of Dr. Murphy in respect of their greater care of children and the comparative sobriety of these intruders.

The Early Treatment of Squint.

THE idea that squint is a condition which will spontaneously subside as the child grows older is no doubt the reason why so often no attempt is made to remedy the defect until after the lapse of many years, until, in fact, much, and it may be irreparable, damage has been done to the visual powers of one of the eyes. Another erroneous idea, also very prevalent, is that if a child be made to wear glasses for the purpose of obviating the tendency to squint, the wearing of glasses will thenceforth be compulsory. It is hardly necessary to point out that the exact opposite is the case, that indeed, if the patient be brought under treatment as soon as the squint is noticed the glasses, in the majority of instances, can be laid aside at or soon after puberty, being, in fact, needed after that period only in presence of some marked error of refraction which would in any event necessitate their use for near work. Now that a commencement has been made with the methodical examination of the refraction in school children, we may hope that a better knowledge of the elementary facts of optics will permeate the masses, increasing the child's perceptive faculties and remedying early the tendency to this disfiguring error of convergence.

Milk-blended Butter.

THE present position of the law with regard to milk-blended butter is anomalous in the extreme, and it is reassuring to note that Mr. Hanbury, the President of the Board of Trade, is of the opinion that fresh legislation is needed. As things go the producer of milk-blended butter is enabled to sell a cheap article and to escape his responsibilities for vending a water-logged butter by simply appending a notice declaring the addition of the milk. As Mr. Hanbury very properly pointed out, in answer to an influential deputation, the customer might easily be imposed upon by such a notice, which naturally enough would convey little meaning to his mind. The honest producer requires protection no less than the consumer, and the morality of a whole trade may be wrecked by the craftiness of particular blenders, who

realise that to sell water at the price of butter is what the man in the street would call "good business." If standards are to be evaded in that simple way by unscrupulous tradesmen, then some other method of protecting the food of the public will have to be invented. There is neither rhyme nor reason in excluding animal fat from butter under all kinds of pains and penalties, while an excess of water may be added with impunity. Mr. Hanbury is of opinion that we should deal stringently with all butter containing over 16 per cent. of water. He would allow a little latitude in the case of Irish brine butter, and said he should press the whole matter upon the attention of his colleagues.

Disused Burial Grounds as Building Sites.

THE Metropolitan Public Gardens Association has done excellent work for years past in securing valuable open spaces to the public. Its example might well be followed in all the great towns of the Kingdom. Quite recently it has called attention to the ever-present temptation to church authorities to allow buildings to be erected on their disused burial grounds. The extent to which this most reprehensible practice has been carried in former times may be traced in the way in which many churches, both in London and elsewhere, are hemmed in and, as it were, bricked up by surrounding structures. That process of appropriation, be it noted, having taken place in many instances before the removal of buried bodies was made compulsory, the sanitary condition of the buildings erected on the churchyard ground is clearly open to the gravest suspicion. Nowadays, when that danger is met by the compulsory clearance of the graves, a wrong is done to the community by depriving it of an open breathing space. This grievance has been insisted upon by the Gardens Association, who have gone to the root of the matter by discussing recent faculties granted by the Consistory Court for the erection of buildings on churchyards. The society in question suggests that it would be well to obtain an authoritative decision from the higher courts as to the legality of such proceedings. The alternative presented by the society is the rational and pleasant one of laying out city graveyards as pleasure grounds.

The Midwives Bill.

THIS Bill, as amended by the Standing Committee, was ordered for third reading on Friday last, but several modifications were made therein which go far to meet some, at any rate, of the objections brought against the measure. Mr. T. P. O'Connor obtained the addition of a clause providing for the removal from the list of midwives of persons convicted of felony or misdemeanour, or who are adjudged by the Midwives Board to have been guilty of disgraceful conduct *qua* midwife. The proposal that the local authority should periodically inspect all premises in which midwives received pregnant or lying-in women, and should issue certificates of registration of same, was obviously beyond the scope

of the Bill before the House, and was rejected. The proposal, however, is certainly one of considerable importance, and if adopted would go far to check immoral and criminal practices. Subsection I was modified in order to provide that from and after January, 1910, no woman shall habitually and for gain attend women in childbirth, or shall make use of the title of midwife? . . . unless certified under this Act. It was also agreed that one member of the Midwives Board should be appointed by the Royal British Nurses' Association. The proposal to extend the scope of the Bill to Scotland and Ireland was negatived, although it was intimated that this might be done by separate measures. On the whole, we believe the Bill in its present form will effect some much-needed reforms. Certain obvious shortcomings in the present measure can be remedied later, when experience shall have shown how it works, and little by little the educational standard can be raised. For good or for evil, the scheme is now on the eve of becoming law.

The Coronation Gynæcological Reunion.

WE are glad to learn that the proposed meeting of gynæcologists and obstetricians of the United Kingdom during the Coronation week has now become a definite arrangement. A reception is to be held at 20, Hanover Square, at 4 p.m., by Sir John Williams, Dr. Peter Horrocks, and Dr. Halliday Croom, and this will be followed by a dinner at the Hôtel Métropole at 7.30, under the chairmanship of Sir John Williams. We cordially congratulate those gentlemen who have been responsible for the inception of such a praiseworthy idea on the success which seems to be ensured for the reunion. Of late, perhaps, various little matters have occurred which have caused slight differences of opinion between many of the members of the gynæcological world, and we confess that we consider that perhaps the most important of the many good effects of the proposed meeting will be the establishment of a common, and we hope enduring, bond of union. We would draw the attention of all those interested in obstetrics and gynæcology who intend to be in London during the Coronation week to the notice which appears in our advertisement columns, as we are sure they will wish to be present at what promises to be a most enjoyable and interesting function.

Pseudo-Phthisis.

IN February, 1846, Addison, when addressing Guy's Physical Society on the conditions that simulate phthisis, said:—"Whatever lessens the freedom, mobility, or elasticity of the ribs renders the sound, on percussion, more dull. Hence it is that in rickety persons, where deformity of the chest has taken place subsequent to birth, the signs furnished by percussion are often extremely unsatisfactory, and, indeed, under such circumstances, neither percussion nor, in many instances, auscultation, can be much relied upon." More than once he returned to the subject, and his monograph on diseases that simulate consumption is an exhaustive study

of the difficulties and fallacies attending the physical diagnosis in diseases of the chest. M. Grasset has this year drawn attention to the subject by a paper on some localised changes in the lungs in rheumatic subjects which produce diminution in the percussion note and other signs of consolidation, and which are, in his opinion, not infrequently mistaken for commencing tuberculosis. He goes the length of saying that many cures in the earlier stage of phthisis, especially in sanatoria, are really only cases of localised rheumatic disease in the lung. Now a case showing tubercle bacilli could not be classed as rheumatic disease, and it is very unlikely that a patient would be sent to a sanatorium until bacilli were found, withal it is worth bearing in mind that the early stages of phthisis are as Addison pointed out, closely simulated by other diseases.

The New President of the Royal College of Surgeons, Ireland.

THE newly elected President of the Royal College of Surgeons in Ireland, Mr. L. H. Ormsby, is well known in Dublin medical circles and holds many important appointments. He is a Graduate in Arts and M.D. of Dublin University and a member of its Senate, one of the senior members of the staff of the Meath Hospital and County Dublin Infirmary, and Surgeon to the National Children's Hospital. In addition, he is a member of the Board of Superintendence of Dublin Hospitals, Governor of the Lock Government Hospital, and Justice of the Peace for County Dublin. We congratulate Mr. Ormsby on his appointment to the Presidency at a time when the College appears to be at last getting clear of the heavy burden of debt which has oppressed it for so many years. It is difficult for a body such as the College of Surgeons, when cramped by insufficient funds, to maintain that degree of expansion and improvement which will alone keep it abreast of the times. But when the period of depression is over, a judicious and wise development of its resources is bound to result. Mr. Ormsby's predecessors have been connected with the period of recuperation. Mr. Ormsby himself will be connected with the period of advance. He is therefore in what perhaps may be considered to be even a more fortunate position than his predecessors, and one which we are sure he will worthily occupy.

THE Court of Governors of Owens College, Manchester, have decided to apply for a charter for an independent university to be called the Victoria University of Manchester.

THE Court of Assistants of the Society of Apothecaries of London have passed a resolution requiring that on and after July 1st next candidates for any examination in medicine shall produce evidence of having received instruction in the administration of anaesthetics at a recognised medical school or hospital.

The Council Election of the Royal College of Surgeons of England.

THERE are now eight candidates for the vacancies on the Council of the Royal College of Surgeons of England and as the date of nomination expired on Monday last, June 9th, the list may be regarded as closed. There are indications that these elections no longer excite the interest which they did when reform of [the College was in the air. No doubt individual surgeons still keenly appreciate the honour and privilege of a seat on the Council, but this may reasonably be explained on the ground that a seat on the Council affords access to the many sources of emolument at the disposal of that body. From the point of view of medical politics the elections really possess no general interest. It is plain that the Fellows intend to the best of their power to reserve to themselves the monopoly with which an archaic constitution has endowed them, so that, whether it be this Fellow or that Fellow, the great mass of the body corporate is absolutely indifferent. Even the annual farce of the corporate meetings followed, as the night the day, by the automatic *non possumus* of the Council, appears likely sooner or later to fall into abeyance simply because it has really no *raison d'être*. The right to offer suggestions without any power of bringing pressure to bear to secure their adoption is such an empty attribute that it is scarcely to be wondered at that it is not appreciated. Gossip has it that Mr. Howard Marsh, who alone among the retiring members offers himself for re-election, is likely to be re-elected, and among the others the betting seems to be in favour of Mr. Clutton, Mr. Golding-Bird, and Mr. Bland-Sutton. The influences which go to preside over the selection of members of Council are of such an occult and variable nature, and are so obviously controlled by coteries and rings and direct or indirect personal influences—in other words, the influence is so foreign to purely professional considerations—that to those without the charmed circle it is quasi-impossible to make even an approximate forecast.

The Treatment of Sepsis following Abortion or Labour.

It is to be feared that in a large proportion of cases the treatment of sepsis following abortion or labour, especially the former, is somewhat inadequate. A more or less perfunctory search is made for any placental structures or clots accessible to digital exploration of the vagina and cervix, removing any such if discovered, and then antiseptic injections, which necessarily fail to reach decomposing material higher up, complete the usual routine of treatment. It is not until acute symptoms of infection supervene that more drastic measures are resorted to, if at all. It is hardly necessary to point out that such mild measures must often fail to afford the patient any protection against the development of subsequent mischief but there is a very decided disinclination on the part of general practitioners to make use of the curette, an instru-

ment which for some reason or other has acquired a bad reputation. After labour, of course, it is usually possible to explore the interior of the uterus with the hand, but after abortion this is virtually impossible unless preceded by dilatation of the cervix, a procedure which may be attended by greater risk than curetting itself. The principle to be laid down is that in presence of a foul discharge associated with a rise of temperature, and other symptoms pointing to sepsis, which do not immediately subside on the removal of *debris* and a few antiseptic douches, curetting of the uterine mucosa is indicated, of course with the usual precautions.

Intravenous Injections of Oxygen Gas.

OUR Vienna correspondent calls direct attention to some interesting and novel experiments which have been carried out by Gärtner bearing on the effects on animals of the introduction of oxygen gas directly into the venous circulation. He found that comparatively large quantities might be introduced with safety, a fact which may later be found to be possessed of considerable therapeutical significance. When the quantity thus introduced exceeds a certain proportion per volume of the blood, symptoms which are sometimes of a more or less alarming character, supervened, but in every instance they quickly subsided on desisting from the experiment. Of course, it is a great step from man to animals, but it must occur to everyone that the possibility of directly oxygenating the blood in this easy manner may place it in our power to combat impending asphyxia much more promptly and effectually than can be done by means of ordinary inhalation. At present the matter is in a purely experimental stage, but it nevertheless constitutes an interesting departure.

The Royal Medical Benevolent College.

WE publish elsewhere a list of the elections at the annual meeting of the Governors, which took place on the 30th ult. The only matter of interest which came up for discussion was the proposal to change the name of the institution to "Epsom College," but it was stated that in view of the fact that the title, which clearly designated the object of the foundation, establishes a certain claim to the notice of possible benefactors it was not thought advisable to do so. Dr. Galton, who had collected £1,000 towards the funds, was elected a vice-president. The financial situation of the College appears to be satisfactory, but it is obvious that its sphere of usefulness is still capable of very great extension, though nothing can be done in this direction until the funds are greatly increased.

A CRISIS in the relations between medical officers and friendly societies appears to be inevitable at Chesterfield. For some time past the medical attendants have endeavoured to secure increased payment for their services, but an open rupture in the negotiations has now taken place, and similar unpleasantness will probably result here as has occurred elsewhere.

The Egyptian Medical Congress.

THE Congress of Medicine, which is to take place in Cairo in December of this year, offers many attractions from a scientific, as well as, nay, especially, from a social point of view. The occasion is one which may well be taken advantage of by practitioners who are desirous of visiting the land of the Pharaohs in that it will afford exceptional opportunities for visiting the principal objects of interest under the most favourable circumstances. The organising committee have arranged a series of excursions for the benefit of members of the Congress who, by the way, may be accompanied by their wives. Among the attractions are the various mosques, the pyramids and sphinxes, the island of Rhodes—the spot, it is believed, where Moses was found in the bulrushes—the ostrich park, the tombs of the prophets, the petrified forest, &c. There will also be an excursion some miles up the Nile. It is anticipated that the principal shipping firms will concede special terms to members of the Congress, and in respect of Upper Egypt Messrs. Cook announce a reduction of 50 per cent. on their ordinary tariff.

The Ambulance Coronation Arrangements.

THE organisation of the Ambulance Service in view of the forthcoming Coronation festivities is being proceeded with, and we are informed that they will be even more elaborate than on the occasion of the Jubilee fêtes. The troops will be provided by the Royal Army Medical Corps, Regulars, Militia, and Volunteers alike, and they will be assisted by the Volunteer Infantry Brigade bearer companies. The Volunteer contingents will be drawn from all parts of the kingdom in order that the various branches may be fairly represented on this historic occasion. Provision has to be made not only for service along the line of route but also for medical attendance for the large number of troops temporarily stationed in the Metropolis. There will be ambulance stations at regular intervals along the line of route, and stretcher detachments from the St. John Ambulance Brigade will supply the facilities for the immediate transport of the sick and wounded, if unfortunately there should be any. The detailed plan will be made public shortly.

A CONVERSAZIONE is to be held at University College, London, on Thursday, June 19th.

PERSONAL.

DR. WILLIAM H. WELCH, of the Johns Hopkins University, will deliver the Huxley Lecture for this year at the Charing Cross Hospital.

DR. R. F. QUINTON, Medical Officer of Parkhurst Prison, has been appointed Governor and Medical Officer of Holloway Prison, *vice* Colonel Milman, retired.

DR. WILLIAM LAMB, M.R.C.P., has been elected Surgeon to the Birmingham Ear and Throat Hospital, and Dr. Wilfrid Glegg, M.R.C.P.E.I., has been appointed Assistant Surgeon.

SURGEON-GENERAL A. F. PRESTON, who acted as

Director General of the Army Medical Staff during the recent interregnum, has just retired, having attained the age limit. He received the Distinguished Service Reward some time since.

DR. ROSENSTEIN has been made a Commander of the Order of the Lion of the Netherlands, and Drs. Könwer, Roessnigh, and Pot have been appointed Knights of the same Order for their attendance on the Queen of Holland during her recent severe illness.

FIELD-MARSHAL LORD ROBERTS, K.G., has consented to preside at the annual distribution of prizes to successful students of St. George's Hospital Medical School, in October next. It is anticipated that the occasion will see a considerable muster of old St. George's men who have been doing good service in South Africa during the recent campaign.

THE past and present patients of the National Hospital for Consumptives, Newcastle, have made a presentation to the Medical Superintendent, Dr. Steede, on the occasion of his approaching marriage. The presentation consisted of entrée dishes and a revolving dish, with an inscription bearing warm testimony to the skill, gentleness and kindly attention which the patients, without distinction of class or creed, had experienced at the hands of Dr. Steede.

WE notice with pleasure that a mural tablet in honour of the late Professor S. O'Sullivan, F.R.C.S.I., was unveiled, on the 3rd inst., in the North Charitable Infirmary, Cork. It was erected by his colleagues of the medical and surgical staff of the North Infirmary in token of their sincere affection and respect. The unveiling ceremony, which was witnessed by a large assembly, was performed by the High Sheriff of the city, who bore eloquent testimony to the high estimation in which the Cork people held Professor O'Sullivan.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE SANITARY CONDITION OF EDINBURGH.

DR. A. M. WILLIAMSON, head of the sanitary department, has presented his fourth annual Report to the Town Council. In addition to the sanitary work carried on in improving and reconstructing properties, nearly 14,000 complaints were dealt with during the year, of which number 13,864 nuisances were successfully abated. In over a thousand cases the visiting inspectors found houses in so filthy a condition as to require them to give instructions for cleaning, while 318 cases of overcrowding (mostly of one-roomed houses) were discovered. It is satisfactory to learn that in dealing with the last named little difficulty was experienced in obtaining satisfactory accommodation for those who were unhoused. As a result of the efforts of the department to do away with underground tenements, it is reported that only nineteen such are now occupied in the city, and it is proposed to deal with them in the current year. Under the head of the Sale of Food and Drugs Act the Report states that a large proportion of the samples taken under the powers of the Act have been of milk. In a few cases in which adulteration had taken place it was possible to obtain a conviction, but Dr. Williamson says there can be no doubt that the law in this respect is in a most unsatisfactory state inasmuch as while a nominal standard of purity has been fixed by recent legislation, the necessity imposed on the prosecutor of conclusively proving that the milk has been tampered with after withdrawal from

the cow completely nullifies the advantage gained. A noticeable improvement in the bakehouses of the city was manifest. Dairies to the number of 490, and 140 cow-byres are now on the register, and during the year 229 samples of milk were taken from animals suspected of diseases which might be communicable to man. The majority of these were tuberculous affections; in no fewer than fourteen instances tubercle of the udder. As regards meat inspection, only one carcass in every 638 had to be destroyed as diseased; but among cattle alone the proportion was higher—1 in 191. During the year the total seizures were as follows:—Beef 72,497 lb, veal 2,192, pork 1,262, mutton 6,412, fish 4,233, fruit 1,255, margarine and sweets 48.

THE RECENT GLASGOW SMALL-POX EPIDEMIC.

In his detailed report on the prevalence of small-pox in Glasgow since April, 1900, Dr. Chalmers, the medical officer of health, deals with the influence of the situation of the Belvedere Fever Hospital on the prevalence of the disease in the easternmost part of the city, and states that a series of comparisons warrant the deduction that the risk of aggregating together small-pox patients begins at a very early period of an epidemic, and that the disease tends to prevail in the neighbourhood of small-pox hospitals. When, however, epidemic virulence is established, the precise influence exerted by the hospital cannot be dissociated from that caused by the independent centres which it has in part produced. The conclusion, however, is inevitable that Belvedere is undesirable for the continued treatment of small-pox. How to meet both contingencies—a recurring epidemic prevalence at long intervals, and the added risk of concentration present at all times, but felt most when the pressure is greatest—is the constant difficulty in providing hospital accommodation for small-pox. To maintain several hospitals constantly equipped for a contingency which, however certain, is yet remote, would mean waste. A certain minimum accommodation must be available to meet minor fluctuations between epidemic periods, but to establish this as the sole centre of aggregation in epidemic periods results in producing a surrounding mass of infection, which may be dealt with but cannot be controlled. The broad distinction between the mortality in the vaccinated, doubtfully vaccinated, and unvaccinated was that at all ages the death-rate in the first group was 9.1 per cent., in the second 54.3 per cent., in the third 51.6 per cent. The number of revaccinations was 413,237, and the amount expended in connection therewith £32,236.

EDINBURGH INFIRMARY OLD RESIDENTS' CLUB.

The eighth annual meeting and dinner of this club, founded several years ago to promote intercourse between past and present generations of infirmary residents, was held in Edinburgh on Friday last, June 6th. The club has been in the habit of presenting a prize in clinical surgery annually, but last year this had to be discontinued for want of funds. The finances are, however, in a more satisfactory condition than last year, and it is hoped in time to accumulate a capital fund sufficient to endow a biennial prize. The club now numbers about 400 members, residing in all parts of the country. Between sixty and seventy were present at the dinner, under the chairmanship of Sir Dyce Duckworth, who travelled from London specially to preside, and a most enjoyable evening was spent.

MR. JOHN SHAW MACLAREN has tendered his resignation of the post of Assistant Surgeon to the Managers of the Royal Infirmary, as he has accepted an appointment as a medical missionary in Rajpootana.

Belfast.

[FROM OUR OWN CORRESPONDENT.]

[We are not responsible for opinions expressed by our local correspondents.]

EPIDEMIC SUSPECT.—We seem to be in for an epidemic of small-pox here, but as the town is probably pretty well

vaccinated it is not likely to be a severe outbreak. There are said to be about twenty cases in the fever hospital at the Union workhouse, but this figure is based on hearsay only, not on published statistics. The question of a proper small-pox hospital is, of course, to the fore, as at present we depend on the accommodation in the fever hospital, which is situated in the grounds of the crowded Union workhouse. Land was secured long ago for the purpose of a large new fever hospital at Purdysburn, close to where the lunatic asylum now is, but, like many another municipal undertakings, the building seems to hang fire. The medical profession has strenuously opposed the scheme, and is almost unanimous against it, as the new hospital will be so far from Belfast that from some parts of the city a drive of seven miles will be necessary to reach it—a drive which, to put it mildly, would be no great advantage to a patient with a well-developed attack of typhoid or small-pox. It is reported that a temporary small-pox hospital is to be erected on the site chosen by the City Councillors for the new fever hospital, and this would appear to be a very good step, for if in practical working the site proves to be as objectionable as the majority of us believe it to be, the erection of the fever hospital on it may be stopped. Meantime, re-vaccination is the absorbing topic of interest, and one day last week the supply of lymph ran short, so great was the demand for it.

ULSTER MEDICAL SOCIETY.—The annual meeting of the Ulster Medical Society has been fixed for Thursday, June 12th, when, in addition to the ordinary business, the Society will take into consideration the Constitution and Rules, as revised by a special committee, in consequence of Professor Whittle's gift of a medical institute. The building of the institute proceeds rapidly, and it is hoped that it may be ready for the opening meeting of next winter session.

Correspondence.

A MEDICAL HERO.—THE SMYTH FUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly allow me the courtesy of the columns of THE MEDICAL PRESS AND CIRCULAR to enable me to thank the Medical Profession for their great kindness to me and my children in connection with Dr. Smyth's death.

My heart is too full of gratitude to express adequately what I feel, but I can only say that I will never forget the generosity of my dear husband's colleagues in the affliction which so suddenly came upon us. I use the columns of THE MEDICAL PRESS AND CIRCULAR as an effective way of reaching the medical profession.

I am, Sir, yours truly,

E. M. SMYTH.

Burton Port, Donegal, June 3rd, 1902.

Medical News.

Medical Benevolent Fund Society.

At the annual meeting of the Royal Medical Benevolent Fund Society of Ireland held last week in the Royal College of Physicians, Sir J. W. Moore read the annual report, which contained the announcement that His Majesty the King has been graciously pleased to become patron of the society. The motion, "That the rule which debar adult orphans of medical men be modified, in order that special cases may be relieved," was considered at a meeting of the Central Committee, held on January 29th. After full discussion, the motion was lost. The acting secretary was accordingly instructed by the Managing Committee to inform all such applicants that they were outside the rules and scope of this society. The total amount of the grants recommended since last distribution is £1,310, exceeding those of the preceding year by 28½. The total number of applications considered during the year was eighty-four. Of these

seventy-three were from the widows of medical men, seven from, or in behalf of, their orphans, and four from medical men themselves. The Central Committee were again able to congratulate County Antrim Branch upon the very satisfactory report which the treasurer, Dr. Richard Purdon, had sent in, showing a net contribution of £157, but the Committee find a disheartening amount of apathy existing among the members of the profession regarding this society. "In one or two counties almost every member of the profession subscribes something towards this fund. In others only three or four subscribe; whilst from some no contribution whatever is forthcoming. Every member of our profession should subscribe towards a society the sole object of which is to assist a professional brother when in distress, or his widow and orphans after his death." The hon. treasurer (Dr. Parsons) having read the annual report, from which it appeared that £1,330 was given away in grants; the total receipts amounted to about £470, and the dividends on stocks £703. Sir Philip Smyly moved and Sir Thornley Stoker seconded the adoption of the treasurer's statement, both urging more active participation. Mr. Thomas Myles proposed:—"That this meeting desires to convey its warmest thanks to the Committee and officers of the parent society, as well as to those of the provincial branches, for their hearty zeal in the Society's beneficent work, and also to those of our student brethren who have contributed a tangible proof of their generous sympathy in the cause." He said a very moderate subscription of 5s. would bring in £750, whereas the amount subscribed was only £390. That was not creditable to the profession in Ireland. The motion was seconded by Sir Charles Cameron and passed. The Central Committee and officers were elected, and a vote of thanks to the chairman concluded the proceedings.

An Unqualified Suicide.

MR. ALFRED MALLETT PIERSON, a "nose and throat specialist," unqualified, living at Paddington, was recently brought to book by the Medical Defence Union, for a libel which he had published on a medical man, and was spared proceedings on giving an apology and paying costs. Last week he committed suicide, and at the inquest a verdict of "unsound mind" was returned.

Annual Meeting of the Royal College of Surgeons, Ireland.

The annual meeting of the Fellows of the College was held in the College Hall on May 31st—the President, Mr. T. Myles, in the chair. The annual report and financial statement of the Council for the year ending April 5th, 1902, was submitted to the meeting. The President briefly explained the principal features of the account for the past year, pointing out that at last the heavy burden of debt, the legacy of the amalgamation scheme, had completely disappeared. During the past two years the £3,000 of capital, which had been previously sold to meet the College liabilities, had been restored, and in addition £1,000 of Consols had been purchased, while at the moment of speaking a credit balance of £570 existed at the bank. The Council, in addition, had made large purchases for the library, and had commenced developing the splendid museum of the College. The curator of the museum had been given a special grant to pay for assistance in the preparation of a new catalogue, but this was a work that would necessarily take some time. As they could see for themselves, the College buildings had been thoroughly renovated, and made worthy of the College. The prospects of the College on the whole were bright, but strict economy and good business management were still necessary to enable the College to maintain its position. Since the last report many of the Fellows and Licentiates had received honours and distinctions for their services in the South African war. Two had received the honour of C.B., five that of C.M.G., one that of C.I.E., three the D.S.O., and one the Victoria Cross. The recipient of the last-mentioned distinction had been recently elected an honorary Fellow. At present the lists showed that there were now living—10 Honorary Fellows, 417 Ordi-

nary Fellows, 2,864 Licentiates, 6 Honorary Diplomates in Public Health, 128 Ordinary Diplomates in Public Health, 499 Licentiates in Dental Surgery. The obituary list recorded the deaths of 9 Fellows, 28 Licentiates, and 4 Licentiates in Dental Surgery during the past year.

An Ill-advised Action.

MR. WILLIAM ARTHUR JONES, L.R.C.S.I., of Camberwell, brought an action to recover damages for libel against the Rev. H. C. Veasey, who had inserted a statement in the *Schools Union Magazine* warning his readers against having any connection with Mr. Jones, on the ground of his notorious immorality. The action was tried in the King's Bench Division last week, when Mr. Jones denied certain allegations impugning his morality, but the jury, without any hesitation, returned a verdict in favour of the defendant.

The Royal Medical Benevolent College.

THE annual general meeting of the governors of the Royal Medical Benevolent College was held on May 30th, at the office in Soho Square, London, W., the Treasurer of the Institution, Dr. C. Holman, being in the chair. The scrutineers announced the result of the voting to be as follows:—

PENSIONERSHIPS: Fanny E. Owen, 10,397; Margaret M. Sheppard, 9,347; Caroline M. Jones, 9,319; Charlotte Johnson, 7,492; Lucy E. Matthews, 4,939; Fanny W. Wilson, 4,339; Sarah Nolan, 3,295.

FOUNDATION SCHOLARSHIPS: Wilfred L. Corry, 8,710; Gerald K. MacNaught, 8,165; William T. K. Wallington, 8,048; John A. Cowan, 7,325; Reginald H. Leigh, 5,625; John H. Stewart, 4,483.

MORGAN ANNUITIES: Matilda S. Rymer, 7,649; Emma Thackthwaite, 3,718; Ann Wilcocks, 3,578.

Fatal Whiskey Explosion.

CAPT. WILLIAM CARE, of the Indian Medical Service, was recently the victim of a distressing and fatal accident at Meerut. Someone having brought a light in proximity to an empty whiskey cask, an explosion followed, causing such serious burns to the unfortunate gentleman that he succumbed to his injuries soon after. Capt. Carr was only 32 years of age.

Royal College of Surgeons, Ireland.

THE Barker Anatomical Prize for 1903, of £21, is offered for competition, and is open to any student whose name is on the anatomical class list of any School in the United Kingdom. The preparations entered must be placed in charge of the Curator before March 31st, 1903. The prize is offered for a dissection of the sole of the foot. Particulars will be furnished on application to the Registrar.

More Antivivisection.

A BILL has been introduced into Parliament by Mr. Bannbury to amend the Cruelty to Animals Act. It provides that where experiments calculated to cause pain are made upon living animals they must be anaesthetised and shall be killed before recovering consciousness, such experiments not to be made except in the presence of an inspector and only for purposes of original research.

Suicide of a Scottish Practitioner.

AN inquest was held at Manchester last week on the body of James Waddell, L.R.C.P. and L.R.C.S.Ed., of Airdrie, Lanarkshire, who died from the effects of an overdose of morphia, taken, according to the verdict, "whilst insane from the effects of drink."

The Adelaide Hospital.

THE annual meeting of this hospital was held last week, Sir Algernon Coote, Bart., presiding. Dr. Wallace Beatty read the forty-fourth annual report of the Managing Committee, which stated that the long-wished-for addition to the Nurses' Home is now almost in readiness for occupation. The wing which has been added during the past twelve months is upon the cubicle system and affords improved accommodation for twenty-three beds, together with a day room. The enlargement of the extern departments and the new operating theatre also approach completion. Over these the heavy debt of £3,800 at present hangs, and a still further considerable sum must be expended upon furnishings and appointments. During the year 1,124 patients were

admitted into the medical and surgical wards, the number being rather more than that of last year. The medical report showed that 559 patients were admitted into the medical and fever wards during the year. The surgical report, which was read by Surgeon Heuston, stated that during the year 1901 565 patients were admitted to the surgical wards, being an increase of forty-five on the year 1900, in which year there was an increase of seventy-four as compared with 1899; 474 operations were performed with ten deaths, giving the very low percentage of 2.11. Mr. Justice Ross moved the adoption of the report and in doing so congratulated the medical staff, the surgical staff, and the nurses, whose work was so well known, on their having had another successful year. After the transaction of the remaining business the meeting terminated.

Pay of Indian Army Medical Officers.

THE Secretary of State for India has decided to approve an increase to the pay of officers of the Royal Army Medical Corps below the rank of Major while serving in India and also the issue of charge allowances for senior medical officers of station hospitals there.

Cork Medical and Surgical Society.

THE annual meeting of the Society was held on Wednesday evening, May 28th. There was a very large attendance of members. The following officers were elected for the Session 1902-3:—President, Dr. P. T. O'Sullivan; Vice-President, Dr. J. Cotter; Retiring President, Dr. T. G. Atkins; Hon. Secretary, Dr. D. J. O'Connor; Hon. Treasurer, Dr. P. J. O'Brien; Council: Drs. W. Ashley Cummins, C. Y. Pearson, N. H. Hobart, T. B. Moriarty, J. Giusani, E. Murphy, and H. R. Townsend. The financial statement showed a large balance to the credit of the Society, the number of members being the largest on record.

Royal College of Surgeons in Ireland.

AT a meeting of the President, Vice-President, and Council, held on Thursday, June 5th, the following were elected Examiners in Surgery for the ensuing year:—Messrs. F. Conway Dwyer, F.R.C.S.; T. E. Gordon, F.R.C.S.; E. Lane-Joynt, F.R.C.S., and E. H. Taylor, F.R.C.S.

Pass Lists.

Dublin University.

FINAL IN MIDWIFERY.—R. G. H. Tate, J. S. Joly, E. B. Booth, J. A. Valentine, C. W. Webb, J. C. Scott, W. Benson, J. H. Askins, H. F. Johns, N. H. MacNicol, E. F. Steel, T. L. Sands.

B.A.O. DEGREE.—H. A. Hanan, W. J. Burke, W. Moyers.

DIPLOMA IN PUBLIC HEALTH—FIRST PART.—F. W. Lamb.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

AIX-LES-BAINS.—The British "Spring Season" here usually terminates in June, the Continental, or "French Season" continuing through the summer. This year everything is "late," so we do not think that our inquirer "Family" would find the weather too sultry for a cure at Aix-les-Bains from June 15th to July 10th. The hot and crowded season at Aix is from July 14th (the French National Fête day) to end of August. In September the English ("Autumn") Season recommences at Aix and continues into November, very conveniently for those intending to winter on the

Riviera, at Montreux, Davos, or Lugano, and in Italy or Egypt, Aix being en route thereto. As for hotels, pensions, and apartments these are abundant and excellent at Aix, and until mid-July you would have no difficulty in obtaining there whatever accommodations your party desired. The hotel you mention, "The Albion," is a very good one in every respect, noted for its cuisine and politeness to its guests. It is located on a hill-side overlooking the park and amidst gardens, yet within five minutes' walk of Baths and Casino. Should furnished apartments be preferred the "Maison Henri Damesin" has always been liked by British families.

Dr. For's letter on "Dover and his Powder" is unavoidably crowded out of present number.

G. L. R.—The number referred to is out of print, but it can, of course be seen at any medical library.

PROF. THOMPSON.—We hope to have space for your communication in our next.

R. P. C. (Dublin).—Dr. Burney Yeo's work on Food in Health and Disease may answer your purpose. (2) Digestion probably goes on during sleep, but the peristaltic movements are slowed, so that food is apt to ferment. (3) We have no reason to believe that magnetic hair brushes have any influence on the growth of the hair except as brushes, brushing the hair having a favourable effect on the local circulation. (4) Nothing positive is known on this subject, but in regard to their influence on "the promotion of health" the suggestion may be dismissed with a smile. (5) You do not say for what department of disinfection the substance is intended. For all-round purposes chinolol answers the purpose very well.

PRIMO (Belfast).—It would require several hours' research in a library to reply to your questions, and we must ask to be excused.

THE BETTER LAND.

Our irrepressible rhymester asks hospitality for the following example of "Medicine in Verse." As we have no "Poet's Corner" this is all we can do for him.

Ther here thee speak of a better land
Where there exists no prostate gland,
Tell me, oh! where is that radiant shore?
Where catheter life exists no more,
Where the bladder remains its normal size,
And does its duty till owner dies,
Where impotente calls no longer vex,
Say? is it somewhere in "Middlesex"?
Not there! Not there! my child!

A. D.

DR. DE LA HARPE.—See reply to Professor Thompson.

THE NEGRO AND THE DOLLAR.

The Canadian Journal of Medicine and Surgery relates the story of a North Carolina negro who swallowed a silver dollar. After this he was troubled with pain in his stomach whenever it became empty, so that he had to eat frequently and much. The coin was passed fifteen days later unharmed, which led his medical adviser to remark that it was the first time a nigger couldn't get a dollar changed in a fortnight. On reflection, the pains which he suffered whenever his stomach became empty would not appear to be pathognomonic since many persons suffer pain under similar circumstances, without having swallowed anything worthy of note. We are directed to observe that when the man had swallowed the dollar, thus loading his stomach, his pocket was empty, a condition which has been known to produce the most profound mental agony with a sensation of an aching void in the epigastrium. Moreover, many a good dollar goes into the stomach of the human animal, the pain in many cases setting in long before the stomach has become empty. In regard to treatment it is suggested that the amount at stake was too small to operate for, so Nature was allowed to take its course. Had it been a gold piece of the same dimensions, Nature would probably not have been allowed a voice in the matter.

Appointments.

BROOK, T. S., M.R.C.S., L.R.C.P.Lond., Medical Officer to the Petersfield Union.

CLAREMONT, CLAUDE C., M.D., Physician to the Royal Portsmouth and Gosport Hospital.

COLMER, PROLEMY AUGUSTUS, M.R.C.S.Eng., L.R.C.P.Lond., L.S.A., Medical Officer to No. 2 District, Yovvill Union.

EYRE, J. W. H., M.D., Bacteriologist to Guy's Hospital, London.

FREEMANTLE, FRANCIS E., M.B., B.Ch.Oxon., Medical Officer of Health to the Herts County Council.

GREEN, REGINALD, M.D., D.Hy.Dunelm, Medical Officer of Health and Medical Officer to Infectious Hospitals for the King's Norton and Northfield Urban Council.

HAYES, DR. BOUCHIER, Medical Officer of the Clifton Dispensary District.

HOLCROFT, W. F., Medical Officer for the North Molton and Moland Districts of the South Molton (Devon) Union.

LAMB, WILLIAM, M.D., C.M.Ed., M.R.C.P.Lond., Hon. Surgeon to the Birmingham and Midland Ear and Throat Hospital.

MCCANN, DR. WM. C., Medical Officer for Longford Dispensary District and Medical Officer of Health for the rural portion of the district.

STARCH, GEORGE RUSSELL, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Resident Medical Officer to the Westmoreland Lock Government Hospital, Dublin.

WILSON, GEOFFREY E., B.C.Cantab., House Physician to the Pad-dington Green Children's Hospital.

Vacancies.

Bristol City Lunatic Asylum.—Medical Assistant. Salary £140 per annum, with furnished apartments, board, and washing. Applications immediately to Edmund J. Taylor, The Council House, Bristol.

Fisherton Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Apply to Dr. Finch, at the Asylum, Salisbury.

Hereford County and City Asylum.—Senior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Kenington Dispensary and Children's Hospital.—Resident Medical Officer. Salary £100 per annum, with furnished apartments, board, coals, gas, and attendance. Applications to J. Holgate Batten, Esq., Honorary Secretary, Church Street, Kenington, W.

London Hospital, Whitechapel, E.—Surgical Registrarship. Salary £100 per annum. Applications to G. Q. Roberts, Secretary and House Governor.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160 per annum. Furnished apartments, attendance, light, and fuel. Applications to Secretary, M. I. Preston, "Journal" Chambers, Nottingham.

Salop and Montgomery Counties Lunatic Asylum, Bicton Heath, near Shrewsbury.—Medical Superintendent. Salary £650 per annum, with house free of rates and taxes, fuel, light, and other allowances. Applications to W. Baxter, Clerk to the Committee of Visitors, Shirehall, Shrewsbury.

Staffordshire County Asylum at Stafford.—Junior Assistant Medical Officer. Salary £150, with furnished apartments, board, &c. Applications to the Medical Superintendent.

Staffordshire General Infirmary, Stafford.—House Surgeon. Salary £120 per annum, with board, lodging, and washing. Applications to Richard Battle, Secretary, 7, Meyrick Road, Stafford.

The Hartlepool Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and lodging in the institution. Applications to Robert M. Edger, 9, Albion Terrace, Hartlepool.

Wills County Asylum, Devizes.—Assistant Medical Officer. Salary commencing at £160, with board, residence, attendance, and washing. Applications to the Medical Superintendent.

Births.

BERENDT.—On June 7th, at 65, Rodney Street, Liverpool, W., the wife of Frank Hugh Berendt, M.D.Lond., F.R.C.S., England, of a son.

MACKINTOSH.—On June 5th, at Grahamston, Troon, N.B., the wife of Hugh J. Mackintosh, M.B., C.M., of a son.

REYNOLDS.—On June 4th, at Highcroft, Highgate, N., the wife of Austin E. Reynolds, M.B.C.S., of a son.

SPILSBURY.—On June 5th, at "The Rise," Hogsthorpe, Lincolnshire, the wife of F. J. Spilsbury, L.R.C.P., &c., of a daughter.

THOMAS.—On June 8th, at Severn House, Lydney, Gloucestershire, the wife of C. Nelson Thomas, B.A., M.B., B.C., of a son.

THOMPSON.—On June 7th at 6, West Street, Scarborough, the wife of Geoffrey Thompson, M.D., of a daughter.

Marriages.

CODD—LEESON.—On June 3rd, at the Wesleyan Chapel, Sutton Coldfield, John Alfred Codd, M.D., B.Sc., of Wolverhampton, to Jennie, daughter of Mrs. Leeson, of Sutton Coldfield.

ESCOMBE STEPHENSON.—On June 4th, at St. James's Church, Grimsby, William Escombe, M.R.C.S., L.R.C.P.Lond., son of the late Bowland Escombe, Esq., of blackheath, to Mildred Isabella, daughter of G. S. Stephenson, M.D., of the Manor House, Grimsby.

Deaths.

ARMITAGE.—On June 2nd, at Wornit, Fife, Walter Stanley Armitage, F.R.C.S., formerly of Edinburgh, eldest son of the late T. R. Armitage, M.D., of Noan, co. Tipperary.

RECENT WORK

ON THE

PHYSIOLOGY OF DIGESTION. (a)

By W. H. THOMPSON, M.D., F.R.C.S.ENG.,
King's Professor of the Institutes of Medicine in the University of
Dublin; Examiner in Physiology, Royal College of Surgeons,
England, and Royal University, Ireland.

SOMEWHAT more than ten years ago an elaborate institute for the experimental study of medicine was established in St. Petersburg. This institute, consisting of numerous departments, is, in short, the Pasteur Institute of the capital of Russia. Two of these are devoted to the prosecution of physiological research, one in the field of chemical, the other, more strictly in the field of experimental, physiology. The director of the former was the late distinguished Professor Nencki, of the latter the no less celebrated Professor J. P. Pawlow. It is to some of the work which has emanated from Pawlow's laboratory that I wish more especially to draw attention. During the whole of the ten or more years which have elapsed since its foundation, the laboratory, consisting of the director, with a staff of assistants, and numerous workers, has devoted itself exclusively to a systematic study of the processes of digestion. The first results of this combined work were given in collected form, about four years ago, as a series of lectures to Russian physicians, and soon after published in the Russian language. The book was translated into German by one of the assistants of the laboratory about a year later, and thus was made more available to the scientific world generally. (b) It is quite a small work, less than 200 pages, but it literally teems with results of the most valuable kind to the practitioner of medicine. The volume was supplemented some months ago by a further fasciculus of less than fifty pages.

From the chapters of the first of these publications, which deal with the subject of gastric digestion, I purpose to draw a few facts, which will serve to exemplify the nature of the work accomplished in Pawlow's laboratory.

OLD METHODS FAULTY.

For long past nobody had been very satisfied with the methods by which gastric juice was obtained in order to study its properties. This, as may be remembered, was by means of simple fistulae leading through the abdominal wall into the stomach. The chief fault of this method consisted of the fact that gastric juice could never be obtained in any quantity, unmixed with food. In order to make real progress it was necessary to possess a method by which the

juice could be collected (1) at all times, (2) in pure condition, (3) in exact quantity, (4) while the stomach functioned normally, and (5) from an animal in perfect health.

PAWLOW'S IMPROVEMENTS.

Pawlow achieved these desirable ends by an improvement of the old method, in which a partially isolated portion of the fundus of the stomach was converted into a little pouch which retained its nervous and vascular connections, and whose mouth was led to an aperture in the abdominal wall. The deeper end of the pouch, as well as the opening into the main portion of the stomach, was securely closed. By the rigid application of aseptic principles of surgery no trouble was experienced in securing rapid and complete recovery of the animals. Then, by means of a glass tube, perforated with numerous small apertures and led into the pouch, gastric juice of the purest quality could be collected in almost any desired quantity.

SOME OF THE RESULTS.

The first interesting fact confirmed by this method was that no secretion whatever occurs when the animal is fasting, but that a copious flow of juice can be set up by the mere act of chewing and swallowing food. This flow commences after a latent period of about five minutes has elapsed, never less than four and a half minutes, and is not due to the entry of food into the larger stomach. The latter was proved in an ingenious way, viz., by making an opening into the œsophagus in the neck, dividing the tube, and causing both ends to heal to the edges of the surface wound. After recovery the animal could be made to chew and swallow food as before, but the food came out at the opening in the neck, and, unless specially led into the lower segment of the œsophagus, did not enter the stomach.

It was then seen that this "sham feeding" caused precisely the same secretion of gastric juice, and that the flow could be kept up as long as the animal could be induced to continue to chew and swallow food. Another modification of the method consisted in making the œsophagotomy as described, together with an ordinary fistula leading into the stomach. The juice excited by "sham feeding" could thus be collected from the whole organ, and not alone from a shut-off segment.

QUESTIONS WHICH PAWLOW SET OUT TO ANSWER.

Having secured an admirable means of studying the work of the gastric glands, Pawlow set out to answer the following among numerous other interesting questions relative to their functional activity:—

1. Is the amount of juice secreted by the stomach in any way proportioned to the quantity of food eaten?
2. What is the way in which the juice is poured out? Is all, or most of it, discharged in one gush at the beginning of digestion, as soon as the meal is

(a) Paper read before the Section of Anatomy and Physiology, Royal Academy of Medicine, Ireland, May 30th, 1902.

(b) It is now translated into English, and will be published in a few weeks by Messrs. Charles Griffin and Co.

partaken of, or, on the contrary, by degrees, and in declining quantities, suitable to the gradual solution and removal of dissolved food from the organ?

3. Does the digestive power of the juice—the amount of pepsin which it contains—vary in any way with the different phases of digestion, or is it constant throughout?

4. Has the nature of the food any influence on the quality of the juice, or are the gastric glands in any way able to adapt themselves to the kind of food presented them for digestion?

■ The answers to these questions, with some of the evidence, I shall endeavour to present to you *seriatim*, and in as few words as possible.

RELATION BETWEEN AMOUNT OF FOOD AND QUANTITY OF JUICE.

We shall take up the answer to the first question as to whether there is any quantitative relation between the juice secreted and the amount of food partaken of. The facts on which the answer is based are shown you in the following table:—

TABLE 1.—RELATION BETWEEN THE QUANTITY OF GASTRIC JUICE SECRETED AND THE AMOUNT OF FOOD TAKEN.

Flesh	{ 100 grms. = 26 c.c. }	} Juice
Diet.	{ 200 " = 40 c.c. }	
	{ 400 " = 106 c.c. }	
Mixed	{ 300 c.c. Milk = 42 c.c. }	} "
Diet.	{ 50 grm. Flesh = 42 c.c. }	
	{ 50 " Bread = 42 c.c. }	
"	{ Double the above Quantities = 83.2 c.c. }	"

■ The figures are taken from experiments in which a dog was "sham" fed with varying quantities, in the first instance, of a flesh diet, and in the second of a mixed one, the juice being collected from the whole stomach. On looking at these, you will see that the chewing of 100 grms. flesh caused a flow of 26 c.c. of juice, of 400 grms. almost exactly four times that amount. Again, a given quantity of mixed diet produced a secretion of 42 c.c., double that amount gave rise to almost precisely double the quantity of juice. The gastric glands, therefore, work in health with the greatest precision, apportioning their labour with beautiful exactness to the magnitude of the task before them. Increase the unit mass of any food by a given multiple, and within ordinary limits, and the glands will respond with a like increase of gastric juice.

CURVE OF SECRETION OF GASTRIC JUICE.

Next comes the answer to the question relating to the manner in which the secretion of juice is spread out over the whole period of digestion.

The reply is taken from figures yielded by two experiments in which a dog was twice fed with 100 grms. of flesh each time, the amount of juice poured out by the stomach pouch being measured hour by hour. They are shown below.

TABLE 2.—HOURLY RATE OF SECRETION OF GASTRIC JUICE.

Two Experiments; dog fed with 100 grms. flesh in each.			
	Exp. 1.	Exp. 2.	
Hour 1	11.2 c.c.	12.6 c.c.	
" 2	8.2 "	8.0 "	
" 3	4.0 "	2.2 "	
" 4	1.9 "	1.1 "	
" 5	0.1 "	1 drop	
Total	25.4 "	23.9 "	

Here you will see that the greatest secretion occurs during the early periods of digestion, but that the juice continues to be discharged in declining quantity as long as any food remains to be dealt with. The glands, therefore, do not pour out all their fluid at once and leave matters to themselves,

but "stand by," paying out more and more with strict economy as long as the needs of the case demand, and the same result repeats itself with stereotyped exactness as often as the same conditions are fulfilled. The course, therefore, which gastric secretion runs follows definite and purposive laws, and is by no means a matter of blind chance.

DIGESTIVE POWER VARIES WITH THE STAGE OF DIGESTION.

And now comes the reply to the third query. If the glands are thus capable of varying their rate of secretion in so remarkable a manner according to the needs of digestion, are they not likewise able to extend similar variations to the digestive power—the pepsin content—of the juice which they secrete? I speak only of pepsin content because Pawlow has shown that the acidity of the juice, as it pours from the glands, is always constant, and varies only because it comes into contact with more or less of an alkaline mucus, which latter in health should only be present in minimal quantities.

The digestive power of the juice was determined by causing it to act on short columns of coagulated egg-white, contained in capillary glass tubes broken into small pieces. The length of column dissolved gives a trustworthy means of measuring the activity of the juice. The results obtained with the juice from two experiments on a dog fed each time with 400 grms. of flesh are given in the next table.

TABLE 3.—DIGESTIVE POWER OF GASTRIC JUICE (QUANTITY OF PEPSIN) AT DIFFERENT STAGES OF DIGESTION.

Two Experiments; dog fed with 400 grms. flesh in each.

	Exp. 1.	Exp. 2.
Hour 1	6.0 mm.	5.8 mm.
" 2	4.5 "	4.1 "
" 3	3.4 "	3.4 "
" 4	3.5 "	3.0 "
" 5	3.8 "	3.8 "
" 6	3.0 "	3.1 "
" 7	3.6 "	3.5 "
" 8	3.9 "	4.5 "

You will see from these figures that the juice secreted at the beginning of the meal has, in the case before us, the greatest digestive power—i.e., contains the most pepsin when presumably it is most required—and that the proportion gradually declines as the need for pepsin likewise decreases during the following stages. The gastric glands then have also the power of varying the quantity of pepsin which they discharge in the juice according to the same laws by which they vary the total amount of secretion poured out.

So far, then, we find ourselves dealing with a mechanism whose adaptation to its work could not be more perfect nor more beautifully conceived.

ADAPTATION OF THE JUICE TO THE NATURE OF THE FOOD.

But the fourth question is perhaps the most interesting of the whole in the series which I have selected. Has the nature of the food any influence on the quality or quantity of the juice? Are the glands capable of adapting their secretion to the kind of food presented them for digestion, and if so, how is this met?

The answer to the first part of the question is undoubtedly in the affirmative; different foods produce different kinds of secretion, the variations applying not alone to the quality and quantity of the fluid, but likewise to the course and duration of its outflow. It would occupy too much time to quote all the experiments on which the facts are based, but these are the chief facts themselves:—

Weight for weight the greatest amount of juice is poured out on flesh diet, the least on milk, bread being intermediate.

The total acidity is greatest with a flesh and lowest with a bread diet.

The digestive power—the pepsin content—is greatest with the juice poured out on bread, least on milk. The relative strengths are represented as follows:—Bread-formed juice, 44; flesh-formed, 16; and milk-formed, 11. Milk, therefore, in agreement with what is known from every-day experience, makes least demands on the activity of the glands for its digestion.

Nor do the peculiarities end here. The manner in which the juice is secreted, and the period at which it attains its maximum digestive power, are likewise different for each class of foodstuff. This is exemplified in the following table:—

TABLE 4.—INFLUENCE OF THE KIND OF FOOD ON THE QUANTITY AND QUALITY OF THE GASTRIC JUICE.

	QUANTITY OF JUICE.			DIGESTIVE POWER.		
	Flesh.	Bread.	Milk.	Flesh.	Bread.	Milk.
Hour 1	11.22 c.c.	10.6	4.0	4.94 mm.	6.10	4.21
" 2	11.3 "	5.4	8.6	3.03 "	7.97	2.35
" 3	7.6 "	4.0	9.2	3.01 "	7.51	2.35
" 4	5.1 "	3.4	7.7	2.87 "	6.19	2.65
" 5	2.8 "	3.3	4.0	3.30 "	5.29	4.63
" 6	2.2 "	2.2	0.5	3.58 "	5.72	6.12
" 7	1.2 "	2.6	—	2.25 "	5.48	—
" 8	0.6 "	2.2	—	3.87 "	5.50	—

Quantities of Food—Flesh, 200 grms.; Bread, 200 grms.; Milk, 600 c.c.

The time of maximum flow occurs, as you will observe, with a flesh diet either in the first or second hour, and both are nearly equal with a bread diet in the first, and with a milk diet in the second or third hour. The period of maximum strength is reached in the first hour with flesh, in the second or third with bread, and towards the end of digestion with milk diet. The differences shown by these figures are most remarkable.

We have now answered the four questions I have selected, and in the following way:—

1. The amount of juice is beautifully proportioned to the quantity of food eaten.
2. The gastric juice is not all discharged at the beginning of the meal, but gradually as it is required.
3. The digestive power also varies at different stages of digestion as the needs of the case demand.
4. The nature of the food does exert an influence upon the quality of the juice.

FIXED MODIFICATIONS OF THE DIGESTIVE FLUIDS TO SUIT PARTICULAR DIETS.

Intimately connected with the foregoing is a further important question, viz., whether the digestive system is capable of permanently adapting itself to a special form of diet or not, i.e., whether the juices secreted take on a more or less fixed character from the long continuance of a special diet. Thus, given a continued preponderance, say, of proteid in the diet, with a paucity of fat and carbohydrate, or, on the other hand, a more than usual proportion of carbohydrate, with a scarcity of fat and proteid, or, lastly, an undue amount of fat, what powers have the digestive organs of meeting these possibilities? The answer is that a condition is gradually established whereby a steady increase takes place in the amount of special ferment necessary to meet the requirements of the particular diet, while at the same time a decrease in those which are superfluous sets in, and once established this condition is to a certain extent a fixed one. Such adaptation is, however, not accomplished through the gastric glands but by means of the pancreas. The main importance, however, of the matter lies in the fact that once having

established such a dietetic adaptation of secretion, it cannot be undone in a day. Great alterations in a dietary, even when urgently demanded, can only therefore be advantageously introduced by degrees.

FLOW OF JUICE FROM "SHAM FEEDING."

And now one point more, before I leave the results which I have selected from this beautiful series of researches. It is, I think, perhaps the neatest determination made in the whole set of experiments. This is none other than an actual estimation of the value of, we shall say for the present, the combined act of chewing and swallowing in terms of gastric juice.

In establishing the fixed rate of secretion for the whole act of digesting a particular meal (which as a matter of fact under like conditions has been found to be always the same) we have determined the value of chewing and swallowing, *plus* the further exciting effect of the food after it enters the stomach. But we can estimate the value of these two factors separately: that of chewing and swallowing in the way I have explained to you, by receiving the food from an opening in the œsophagus and not allowing it to enter the stomach. The other factor is known if we bring the same meal directly into the main stomach of the animal through an ordinary gastric fistula, and observe its effects on the secretion as shown by the stomach pouch. Food introduced in this manner is not nearly so powerful an excitant of juice flow as when it enters in the usual way. But the curious fact comes out that the sum total of the "sham feeding" or swallowing juice, *plus* that caused by the mere introduction of food, is exactly equal to the quantity excited by the whole meal, swallowed and digested in the ordinary way. This is strikingly illustrated if the results be plotted out in curves. It will then be seen that the curve compounded of the "sham feeding" juice, *plus* that from direct introduction of the food, is an exact replica of the curve obtained from the whole meal swallowed and digested in the usual way.

When we have, therefore, any two of the foregoing factors, we can readily determine the third, and in this way we learn that the whole of the earlier part of the secretion is an accompaniment of the act of chewing and swallowing, and not at all dependent on the mere entry of food into the stomach.

Now this "sham" juice, if we may so call it for shortness, is not only copious in amount but of a very active character. It constitutes, therefore, a most important part of the whole. But although an accompaniment of, and apparently caused by, the combined events of chewing and swallowing, it is not really so.

VALUE OF APPETITE IN CAUSING SECRETION.

The same secretion can be excited by the mere sight of food when accompanied by an eager desire on the part of a hungry animal to have it. This implies that the food is such as will excite a keen desire, and, without it, the chewing and swallowing are wholly ineffective.

But what is most important for us in this is that everything which aids in creating the desire for food, and in augmenting the satisfaction of having it, has its material value in an increased flow of the best and most active gastric juice.

Hence the advantage of set preliminaries to the chief meal of the day. The customary ablutions, the change of raiment, the dismissal from the mind of business anxieties, the table decorations, the plan of the meal, the savoury odours, and last, but not least, the expectation of finding an appetising repast, these are all matters of moment, and have their fixed values in terms of active gastric juice.

Much more of interesting and valuable matter might have been selected from these chapters on digestion, but I prefer to err on the side of brevity

NEED FOR CHEMICAL WORK IN CLINICAL RESEARCH.

It would be ungracious of me to find fault in any way with the excellent clinical work done in this country, even if I possessed the authority or had the wish to do so. That is not my purpose. But I may perhaps be permitted to indicate a line of work which might, I think, be more cultivated, and which, I believe, has great possibilities connected with it. It is work which will necessitate a considerable expenditure of time and trouble, but these considerations must not stand as serious obstacles in our path when the end in view is an important one. The line of work to which I refer consists in the fuller application of the methods of chemical physiology to clinical work.

Some years ago, a method of examining the contents of the human stomach was advocated by Ewald. This consists in the introduction of a soft tube at a given time after a test meal, whereby the contents can, without much discomfort, be syphoned off or expressed out of the organ. The method necessitates a careful chemical examination of the juice obtained, and when this is done I am told it yields information of the most valuable kind regarding disease, which cannot be obtained in any other way. But is this method, which I think I may call a physiological one, adopted with sufficient frequency in our country? Are the chemical examinations which it entails carried out with sufficient thoroughness?

Again, in the majority of departures from health, the importance of quantitative variations in the composition of the chief excreta of the body outweighs in value the qualitative. And yet, are quantitative chemical determinations of these ingredients carried out to the extent, and with the degree of precision, that their importance demands? Nay, more, are the means for such examinations adequately supplied by the numerous great institutions devoted to the treatment of disease throughout our country?

Lastly, it must often be almost imperative in such perverted conditions of body metabolism as one meets with in the various kinds of diabetes, of leucocythæmia, of Addison's disease, in obscure fevers, or even in ordinary fevers, to possess a complete picture of the whole metabolism from beginning to end, from the ingesta to the egesta. It is only by thus seriously grappling with such problems that real progress can be achieved.

NEED FOR CHEMICAL LABORATORIES AS HOSPITAL DEPARTMENTS.

And yet what clinical hospital in our land is adequately equipped to afford its staff the necessary amenities for carrying out such a series of investigations? I do not imply that there are no facilities for such work, but they are all too few, and the laboratories are not as they should be, integral parts of every large hospital, just as much as well-equipped operating theatres are at the present time. That it is by no means impossible to carry out such a scheme is shown by the fact that it is adopted, for example, in the Johns Hopkins Hospital in Baltimore, and in many of the Kliniken in Germany.

The Liverpool School of Tropical Medicine.

The Liverpool School of Tropical Medicine, although young in years, has distinguished itself by the admirable work it has already accomplished. It is now proposed to send out a new expedition to the Gambia and Senegambia to study "trypanosoma." These flagellata have been found in the blood of Europeans. They are somewhat similar to the organism producing tsetse fly disease. The chief object of the research party is to investigate the conditions under which the disease occurs in both Europeans and natives, and its distribution and channels of infection.

HÆMORRHAGE INTO THE SPINAL CORD DURING PREGNANCY. (a)

By ALEXANDER BRUCE, M.A., M.D., F.R.C.P.E.,
Lecturer on the Practice of Medicine in the Edinburgh School of Medicine; Assistant Physician to the Edinburgh Royal Infirmary.

HÆMORRHAGE into the spinal cord is an occurrence of great rarity. It has been denied that it ever occurs as a primary lesion, and it is asserted that wherever it is not traumatic it is due to myelitis. It is now, however, known that it may occur primarily as the result of trauma, in consequence of alterations of atmospheric pressure (caisson disease) or spontaneously. Of a series of 126 recorded cases, fifty-five were traumatic, twenty-six were secondary to other lesions of the cord, and forty-five apparently spontaneous. Of these last, ten were due to passive congestion, ten to arterial degeneration, nine to blood diseases, and sixteen to unknown causes. The author's case was interesting as showing how readily the lesion causing hæmorrhage might be overlooked, as illustrating the reliability of an absolutely sudden onset as a criterion of spinal cord hæmorrhage, and as an example of the effect of a cord lesion on labour. The patient was a hawker, æt. 31, who lived among very poor surroundings, and was pregnant for the eighth time. During her previous pregnancies she had always suffered very much from severe vomiting, and this one was similar to the previous ones in this respect. On October 31st, during an attack of vomiting, she suddenly felt something give way in her right side about the level of the waist, and was seized with vertigo, pain all over the body, and complete loss of power in the legs and right arm. The latter passed off in a few hours. Next day the pain persisted, there was constant vomiting and retching, and the legs remained totally paralysed. On admission to hospital the lower part of the body was completely anæsthetic to all forms of sensation as high as the seventh dorsal spine and to the level of the nipples anteriorly, and this anæsthesia remained to the end of life. There was total flaccid paralysis of the legs, the left knee-jerk being absent, and the right but slightly present. There was no ankle-clonus; the plantar reflex showed double extensor response. The bladder was distended, and no urine could be passed; there was also retention of fæces. The patient was five months pregnant, and as the abdominal muscles were paralysed and relaxed the abdomen had become distended, and respiration was greatly hampered. The subsequent progress was that the flaccid paralysis remained unchanged to the end; retention of urine lasted till December 10th, when dribbling set in, and constipation persisted throughout. A curious twitching of the tendons of the arms developed, and also a patch of anæsthesia on the inner aspect of each arm. On November 13th the intrinsic muscles of the hands became weak, and this spread first to the flexors and then to the extensors. This was the order in which these centres lay in the cord, reckoning from below upwards. The paresis of the arms was temporary, and disappeared completely. On November 27th fetal movements were felt, and on December 14th the patient was delivered of twins. The labour was absolutely painless, and the patient was quite unconscious of it. The fact that labour was going on was only discovered through a nurse perceiving that liquor amnii was escaping from the vulva. The patient died on January 6th from bronchitis and exhaustion. On post-mortem examination the hæmorrhage into the cord was found to extend from the sixth cervical to the

(a) Abstract of a paper read before the Edinburgh Medico-Chirurgical Society, June 4th, 1902.

twelfth dorsal segment, having burrowed along and torn up the anterior horn of grey matter. It had apparently originated in an angiogliomatous tumour, of which several were found under the spinal meninges, in the substance of the cord, and in the lateral lobe of the cerebellum. Besides this, a condition of syringomyelia or hydromyelia was present, and the blood had found its way into the tube so formed. Dr. Bruce then referred briefly to the recorded cases of labour—painless and otherwise—in paraplegia, pointing out that in those in which the lesion was in the lumbar enlargement only the first stage went on naturally, and that assistance was needed when the head entered the pelvis.

INTRA-PERITONEAL RUPTURE OF THE BLADDER. (a)

By J. SHAW McLAREN, F.R.C.S.ED.,
Assistant Surgeon, Edinburgh Royal Infirmary

As compared with the frequency of injuries to the other abdominal viscera from violence, intra-peritoneal rupture of the bladder (apart, that is, from extensive smashes of the pelvis) is a comparatively rare accident, but 190 cases in all having been recorded, with only twenty-three recoveries. The accident may be caused by comparatively trifling violence, such as stumbling and falling forward on the ground if the bladder be full. It seems to be a universally accepted theory that the bladder only gives way if over-distended, as in alcoholic intoxication, but in one of my cases the bladder had been entirely emptied only half an hour before the patient had been thrown out of a dog-cart and sustained the accident. In such a case I think that the "tone" of the bladder must be taken into account. We know that the organ sometimes retains a much larger quantity of water than at others, in other words, that it sometimes appears to be tightly stretched over a comparatively small amount of urine. If this be so rupture may occur even if the organ be not greatly distended. Rupture usually takes place at the posterior superior part of the bladder, because this is the weakest and least supported place. It is not necessary to suppose, as was formerly done, that rupture here is due to impact against the sacral promontory. The commonly vertical direction of the tear is against this view, and is to be explained by the fact that the circular muscular fibres are very thin at this part of the organ. The main symptoms of intra-peritoneal rupture are shock, pain in the abdomen, vomiting, inability to stand, desire to urinate, and the passage of a small quantity of blood-stained urine. In one of my patients the extravasated urine formed a large tumour to the left of the umbilicus; in the other there was a history that as the cart wheel passed over the abdomen "water squirted from the penis." This is a symptom which does not seem to have occurred in any of the cases hitherto reported. The cardinal and characteristic symptom is the passage of very small quantities of blood-stained urine—*blütige Anurie* as the Germans happily call it. On passing a catheter the bladder is found contracted and empty. The injection test consists in introducing a definite quantity of water into the bladder, and noting if it can all be withdrawn again. If only a part returns it is a sign of rupture, but the recovery of the whole does not exclude the accident. In a patient in whom this test was applied more than once it was found that sometimes the whole of the fluid injected could be withdrawn, while at other times only a part was got back. On post-mortem examination the rup-

ture was discovered very near the neck of the bladder, so that when the catheter was introduced far into the organ its point occluded the tear, and therefore at such times the whole of the fluid could be withdrawn. Such a case shows that the test is not always absolutely trustworthy or diagnostic. Inflation of the bladder with air which, if a rupture exists, escapes into the general peritoneal cavity and causes disappearance of the liver dulness, has been suggested, but is not an advisable test. In cases of doubtful diagnosis the symptom of *blütige Anurie* is of the highest value, and far outweighs all the rest. Theoretically it may also result from contusion of the kidney or rupture of the urethra, but in each of these other symptoms co-exist, and their differential diagnosis is not difficult. Sometimes in rupture of the bladder the symptoms are delayed for days, but even in such cases the history will show that immediately after the accident the patient has passed bloody urine in small amount. Death in this condition is due either to septic peritonitis or uræmia. The urine is normally aseptic, and it is probable that the organism gains entry into the peritoneal cavity from the bowel, which is injured at the date of the accident. As regards treatment, McCormac was the first surgeon who was able to report successful cases of suture. There are three points which seem worthy of consideration, viz., (1) Should the mucous membrane be sutured? In most cases of recovery the surgeon has united only the outer coats of the bladder. Personally, I have found suture of the mucosa a most difficult and tedious procedure, though probably the use of the Trendelenberg position would render it easier of accomplishment. (2) Should the peritoneum be drained? This is a matter of individual taste, but personally I prefer doing so. (3) Ought a catheter to be tied into the bladder? I think not, as it is proved that immediately after suture the bladder can hold from six to ten ounces without leakage, so that it is sufficient merely to draw off the water every two hours or so at first.

Paris Clinical Lectures.

THE LYMPHATIC GLANDS IN TUBERCULOSIS AND SYPHILIS.

By. DR. LOUIS JULLIEN,
Surgeon to St. Lazare, &c.

ACCORDING to Augagneur, Chauffard, Labbé, Haan, Cao, Franceschini, and others the lymphatic glands play the part of safeguards to the organism, being, indeed, to the lymphatic system what the spleen is to the circulatory system, i.e., organs for dealing with and destroying poisons within the organism. By them infections are prevented or, at any rate, attenuated, and the organism is thus protected. I seem to recognise a faint echo of the theories of days gone by, when we used to be told that: "The two chancres are both produced by a single virus, with effects which vary according as their secretions are absorbed by the veins or by the lymphatic glands; if fortunately by the latter, a bubo is formed, by which the virus is eliminated and the patient saved from syphilis."

Consequently, when syphilis was accompanied by marked glandular enlargement, it was described as being a mild form, as, for instance, in children in whom the glandular system is largely affected. It was the fashion to contrast the uneventful course of these cases with the special severity of the infection in elderly people, whose glands

(a) Abstract of paper read before the Edinburgh Medico-Chirurgical Society, June 4th, 1902.

have generally undergone atrophy. Haan records the case of a man from whose right groin the glands had been removed consequent upon a lesion of the foot, and this patient, having become syphilitic, developed a confluent papular florid eruption on the right side and hardly anything on the left; in addition to this, sixteen months later, following on a vigorous rubbing, a papulo-pustulous eruption made its appearance over the same regions, while the left side, which was protected by the healthy glands, was little if at all affected. A similar case was reported by Cao, concerning a patient who, having been deprived of the axillary and inguinal glands of one side, was attacked by a unilateral specific eruption. A third observation is still more characteristic, since the right thigh and buttock, and also the whole of the right side of the abdomen, were attacked, while no trace whatever could be found on the rest of the body. This occurred after free incision of the right groin, on account of a glandular abscess.

I, too, am enabled to adduce a similar case. I had under my care a woman suffering from a simple chancre with inguinal bubo on the right side. Several incisions had had to be made, and the glands were almost completely destroyed by the prolonged supuration; three months later the patient was admitted to the St. Lazare Hospital suffering from a commencing syphilis, and nothing could be more striking than the rose-coloured papular eruption predominating over the right side of the belly, and involving almost exclusively the leg and thigh of the side deprived of glands.

Only one conclusion can be drawn from these facts, and it is self-evident: in syphilitic subjects all causes of traumatic or spontaneous damage to the glands must be avoided. In such patients an essentially conservative attitude is indicated in dealing with affections of the glandular system, because, by depriving them of their glands, we deprive them of an arm of defence; lastly, when unfortunately the protecting organs are already seriously affected, as, for example, in scrofulous, lymphatic, tuberculous, and leukæmic subjects, it is necessary to double the dose of the remedy and to push the treatment to the utmost.

The laboratory, too, furnishes an argument of its own. MM. Bezancon and Labbé have demonstrated by numerous experiments the appearance of leucocytes in the infected gland which were absent in its normal state, and the organisation of the phagocytic function by the polynuclear leucocytes, the fixed cells of the reticulum and the endothelial cells applied to the surface of the cords and follicles. Manfredi, of Palermo, on the other hand, has observed an attenuation of the virulence of various bacteria, pneumococcus, Eberth's bacillus, Koch's bacillus, plague, anthrax, &c., after having passed them through a series of lymphatic glands in different animals; but he attributed this influence to a bio-chemical action, intimately connected with the special structure and function of the lymphatic glandular apparatus.

All these facts are indisputable, and it is in error that certain clinicians have refused to accept them, or, at any rate, to accept the obvious deductions to be drawn therefrom. These observers ought to have borne in mind that these experiments and facts only concerned the onset of the infection, an ephemeral and almost negligible period, in view of the gradual, slow, and progressive course of such a disease as syphilis.

The glandular inflammation is very soon followed by inertia and impotence; the resources of the organism are exhausted, the supply of polynuclear cells being hindered or insufficient, the capsule broken down, and the infective bacteria are masters of the

situation and establish themselves therein. Thus in cancer we observe the reactional precancerous adenitis, a pure phenomenon of irritation and defence, give place to neoplasia in secondary deposits, from which fresh irradiations take place. We then discover that the morbid agent finds in the lymphatic glands an excellent culture medium. It develops, prospers, and each adenitic centre becomes a revictualising depot for the infection, which is thereby stimulated and intensified. If we endeavour to ascertain the ultimate results of this glandular action we find that more than one virus which would have been ill-received in the general circulation, more than one microbe which would have met its death in contact with the red corpuscles, serum, or alexines, has preserved its vitality simply because it was retained in a glandular centre, in which it finds a ready-prepared culture liquid in a warm chamber admirably suited to its development. What is true in respect of development is even more so in regard to the preservation and almost indefinite latency of the germs.

Chance lately brought under my notice two cases of infection which were of the nature of very instructive experiments. Two surgeons sustained deep wounds of the finger while operating on a syphilitic woman, and only washed their hands after they had completed the suture and dressing. There had been an intimate intermixture of the two circulations, that of the patient and of each of the wounded surgeons. Both were contaminated, but in an altogether abnormal manner, since they had neither chancre nor glandular enlargement. In both of them the lymphatic stage was suppressed, and, towards the thirtieth day, a specific eruption suddenly made its appearance. In these cases the rapidity of the generalisation, thirty days, instead of a minimum of sixty-seven, clearly demonstrates the arresting and delaying function of the gland. On this point there is no room for any divergence of opinion—one phase of the circulation having been done away with, the syphilitic invasion is *pro tanto* shortened. But it would be incorrect to state that the infection was remarkable for its gravity; on the contrary, it was a particularly mild course, being limited, in fact, to a very transitory roseola and to very trifling mucous patches. Now, these two cases are in open opposition to Augagneur's theory, and this is not the only objection we have to raise against it. Along with the elderly persons, in whom the disease runs a severe course, we meet with others in whom it accomplishes its evolution almost imperceptibly, as was shown by Dulac (of Montbrison) in his well-known thesis. A little chancre, a scanty dry eruption which soon disappears, and no trace of constitutional disturbance. It looks as though the virus did not find sufficient nourishment to establish itself in the worn-out organism with its much-reduced vitality, and that consequently the lesions themselves undergo atrophy to such an extent that the infection becomes but a mere skeleton of its normal self. Sigmund (of Vienna) called attention to these facts, which, according to him, are by no means of rare occurrence among the inmates of asylums for the aged.

I would add that, in many of the graver cases, glands have been described by numerous clinicians to have been very markedly enlarged; indeed, this was regarded as an unfavourable element in the prognosis by the classic authors, and Gémey indeed affirms that this is very frequently met with among the natives of Algeria, who are renowned on account of the extraordinary severity of syphilis among them, the disease existing endemically.

When, after the onset of the disease, we witness a prolongation of the period of epitrochlear, cervical,

and inguino-crural adenopathies, are we not justified in drawing certain conclusions as to the persistence of the materies morbi? According to Virchow the germs are not preserved in the blood, in which they only appear at more or less prolonged intervals, but in the depth of the lymphatic glands. We have slightly modified this point of view. We hold that wherever the virus has established itself there may remain in a latent state, and that for many years, morbid survivals which may be revived under influences yet to be discovered. We hold that any part once attacked by the infective agent is predisposed to a fresh attack; in other words, our senses, sight and touch, are coarse instruments, incapable of enlightening us as to the enduring susceptibility of the once damaged tissues, from the skin which the blue lens shows us to be permeated for so many months after the roseola to the viscera which have not escaped during the florid stage, and from this point of view we must take into account the glands, which, as much and even more than any other organ, may undergo changes, and more than any other are adapted to remain the receptacle and assure the preservation of the virus. Consequently, it is to them that we must look when we desire information as to the activity of the virus. By them we know whether the little flame is extinguished or is still burning. Professor de Amicis, of Naples, very wisely insists on these facts in a remarkable monograph, which shows me, to my great satisfaction, that our ideas exactly coincide. The cases which he alleges in support of this opinion are worth mentioning.

A man, *æt.* 50, had had syphilis for twenty-seven years past, when he was attacked by a nocturnal type of neuralgia, occupying the region of the right hypochondria. All the usual drugs were tried in vain, when the professor, on discovering the existence of an enlarged epitrochlear gland, put the patient under specific treatment and cured him. In a man in whom the infection was thirty-nine years old, periostitis of the tibia, with tuberculous syphiloderms of the side, was also associated with the same symptom. Then we have a laryngostenosis twenty-three years after the initial chancre, and a sarcocele twenty-eight years after, the nature whereof was clearly revealed by the same fatal sign. Under similar conditions I was enabled to make an observation of the same kind in one of my patients who was admitted to the Hospital of St. Lazare, suffering from an eruption of syphilitic tubercles on the right side. The diagnosis left no room for doubt, but what struck me was that the glandular system was the seat of extremely well-marked changes; on the right and left the epitrochlear groups and the branches connecting them presented considerable hypertrophy; the same phenomenon obtained in respect of the pre-auricular glands, which were much swollen under the influence of the specific germs, and it was only by putting my patient under intensive treatment that I effected a cure.

Well, gentlemen, the theory under discussion cannot be dealt with conclusively on purely clinical data. The facts from the laboratory remain true, but the observations of our predecessors remain, and I think that I have proved to you that they are by no means irreconcilable, on condition of according a proper place to each of these factors, and that place only.

ONE of the features of the King's Coronation Dinner to the London poor will be the distribution to the guests of King's Chocolate Boxes, to the number of 560,000. The chocolate, we note, is supplied by Messrs. Rowntree and Company, Limited, of York, to whose generosity the recipients owe the artistic boxes in which the chocolate is contained. We have seen one of these boxes, which is worthy of the succulent contents.

Clinical Records.

A CASE OF TYPHOID WITH DOUBLE PNEUMONIA.

By E. P. MARETT, L.R.C.P., L.R.C.S. Edin.,
St. Lawrence, Jersey.

F. V., *æt.* 5, was taken ill just after Christmas with the usual symptoms of typhoid fever. As diarrhoea was a marked symptom I put her on milk diet, which, at the end of a fortnight she refused, having got tired of it. A week after I first saw her she developed a slight cough, which soon became very troublesome, and ultimately she developed true pneumonia. The little patient, at the end of the third week, was in a very grave plight, with continued high fever, feeble, almost imperceptible pulse, and great emaciation. In spite of most careful nursing on the part of the parents the child developed a bed sore, which gave us a great deal of trouble.

The nutrition of my little patient proved a very difficult question, and at the end of the third week it occurred to me to give a trial to Mellin's Food, which I gave every four hours to begin with. She seemed to like it, indeed, she took to it very readily, as a change from the milk, which she absolutely loathed. She began with 20 ozs. a day, as I did not think it prudent to give more at first, the vomiting having been extreme, and she was depending also on rectal injections for nourishment.

During the fourth week the vomiting decreased, the rectal injections were reduced, and I was able to increase the allowance of the food to 40 ozs. a day, given in doses of 5 ozs. at a time, every two hours. The pneumonia was running a normal course, but the chief obstacle was the emaciation, which was extreme; in fact, one could literally "count every bone in her body," and at every prominence it seemed as though the bones must come through the skin.

The parents did all they were told with the aid of cotton-wool, &c., to prevent it, but in spite of every precaution the child developed several raw places wherever two bones rubbed, as, for example, the knees and ankles. This was doubtless due to the child being so restless from pain that she was continually trying to alter her position. In the fifth week I ordered the food to be given every hour, 2 ozs. at a time, with a teaspoonful of brandy at every fourth meal.

The fever subsided and the child became free from abdominal pain and tenderness, and the sixth week was passed fairly well. At the end of the sixth week, however, she had a relapse, with a return of the fever and depressed condition of pulse, &c. This lasted about a fortnight, and at the end of the ninth week she had another relapse which lasted three weeks and left her, as may be imagined, in a shocking state. During all this time she took Mellin's Food regularly, and never once refused it or seemed to tire of it.

At the end of the twelfth week the emaciation was extreme, and was made worse by the fact that during the third attack or second relapse she had lost a large quantity of blood by the bowel. From this date (the thirteenth week of the disease) she began to mend, and she now took Mellin's Food every half hour, half an ounce at a time, in milk and brandy.

I think it only fair to state my conviction that the patient's gain in flesh was chiefly due to Mellin's Food, and its great advantage in the case was that the child took it well and willingly, when she refused milk, milk and barley water, &c. Had she not taken her food so well, the case must have ended fatally, for it is impossible for me to give an adequate idea of the debility, emaciation, and loss of all strength which were present; no one who saw the child ever thought she could live, and I was surprised myself that she did. She is now getting on very well, gaining in health and strength daily, and is still taking the food.

DR. CHARCOT, of Paris, is one of a party proceeding to the Faroe Islands in order to make a special study of the epidemic of cancer which has broken out there.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD ON FRIDAY, MAY 30TH, 1902, AT THE
ROYAL COLLEGE OF SURGEONS.

Professor D. J. CUNNINGHAM in the Chair.

PROFESSOR BIRMINGHAM having been called to the Chair, the PRESIDENT read a paper on, and exhibited a model of,

THE STOMACH IN THE CHILD.

The model exhibited was made from the stomach of a child, *æt.* 2½, and was obtained some years since, prior to the introduction of the formalin process. The method he adopted was that of making a series of vertical sections through the frozen body, commencing in the mesial line. By this means he secured a series of slabs which were removed as required, and then a wooden model of the stomach was made. The specimen from which it was made had been previously removed from the vertical slabs and hardened in spirits. He confessed to a feeling of surprise when he found the stomach of so young a child in the horizontal position, with the œsophagus entering it on a line slightly anterior to the lesser curvature and at a right angle to the direction of the body of the viscus. It might also be noticed that the inferior surface of the organ was slightly flattened and marked with an indentation of the spleen from pressure of that gland. All this was so opposed to preconceived views that he sent the model to Professor His, who was then engaged in similar investigations, for his opinion. His, in reply, said that the vertical position of the stomach in early life was the rule, and he looked on this horizontal condition as abnormal. The second specimen was that of the stomach of a chimpanzee, prepared by the formalin method, which shows an identical condition of affairs.

Professor BIRMINGHAM said the specimen of the chimpanzee showed very beautifully the S curve of the pyloric extremity which formed the antrum of the pylorus.

Dr. T. G. MOORHEAD said that in examining the position of the stomach in *foetuses* by the formalin process he found some were vertical in position and some horizontal—there seemed to be no constant condition.

Professor Cunningham having resumed the Chair, Dr. T. G. MOORHEAD read his paper on

THE WEIGHT OF THE VISCERA IN THE RIGHT AND LEFT SIDES OF THE MESIAL PLANE OF THE ABDOMINAL CAVITY.

The object of this paper was to prove that as early as the fifth month there is a preponderance in weight of the viscera lying to the right side of the mesial plane in the *foetus* over those in the left, and that this difference is due to the grouping of the abdominal organs. The average weight in the right side represented 52·8 per cent. of the total weight of the viscera, as against 47·2 per cent. in the left side. The child therefore enters upon its extra-uterine existence with a marked right-sided bias.

Professor CUNNINGHAM said the paper was most valuable, dealing as it did with the centre of gravity, a subject which had not been dealt with since Professor Struthers published his paper in 1863, which was almost directly due to Buchanan's views on the position of the centre of gravity in the human body. Struthers' investigations were on the adult body, and he had not the advantage of the formalin process; he also included the limbs in his calculations. He (Professor Cunningham) was of opinion that the bones of the right upper extremity, and to a slight extent the muscles also, were weightier on the right side. He felt that they were all much indebted to Dr. Moorhead for his paper, and he hoped they would have further papers dealing with the subject in the adult male and female.

Professor BIRMINGHAM said he thought the paper very interesting, though it had little bearing on the curious question of right-handedness, which he looked

on as more due to the influence of the muscles of the forearm than to the location of the centre of gravity.

Professor W. H. THOMPSON read a paper on

RECENT WORK ON THE PHYSIOLOGY OF DIGESTION, which will be found in another column under the heading of "Original Communications," page 645.

Professor CUNNINGHAM said the paper just read was one of the most important and interesting contributions ever made to the Section, and the subject was so lucidly dealt with that it was made intelligible to all.

Professor SCOTT said he thought some of the facts were open to a different explanation; the quality as well as the quantity of the proteid had to be considered. He also demurred to the conclusion that milk was easy of digestion; it might appear so because of its small percentage of proteids (4 per cent.) as compared with meat (20 per cent.) He would like to know if the secretion stimulating the pancreas was that of Brunner's glands.

Professor O'SULLIVAN said he could not altogether understand what Professor Pawlow meant to convey by saying that secretine which he prepared from the succus entericus acted by working backwards through the blood vessels and not by absorption through the mucous tissues.

Dr. KIRKPATRICK said he would like to know if the percentage of acid varied with the pepsine. He looked on the subject from the point of view of tuberculosis, especially in childhood. How does the bacillus escape digestion? If the secretion in the early stage of milk digestion is small in amount, and weak in ferments, it is of course intelligible that the bacillus may pass through the pylorus in the early stage of the process, and so escape.

Professor BIRMINGHAM said he has always found the pylorus closed during periods of rest. He looked upon its being open as an active condition, and he would like to know how this harmonised with Pawlow's theory that the closure was a reflex act.

Professor W. H. THOMPSON, in reply, said: Pawlow found the pylorus closure to be a reflex act caused by the free acid in the duodenum. When the acid was neutralised by the succus entericus the pylorus opened again, and this process continued until the digestion of the stomach contents was completed. He did not find a reflex opening, but he did find a reflex closure. Pawlow showed that the sight of food inhibited muscular movements of the stomach, as if the viscus was so adapted to receive food. The percentage of pepsine and acid was constant; tubercle infection in early life is to be accounted for by the greater activity of the lymphatics in childhood. The non-permeability of the mucous tissues, and the permeability of the vascular, is analogous to the dialysis of solutions. Pawlow found that cold water was one of the best stimulants to reaction, taken at the beginning of a meal; next in order, but much less efficient, was meat extract. Contrary to accepted ideas sodium solution was found to inhibit gastric secretion. In this connection Pawlow made many interesting experiments with milk, and he found that milk fats inhibited digestion; his (Pawlow's) experiments were conducted with ordinary milk, milk to which cream had been added, cream, and milk deprived of all its fats, and he found that the digestive action was inversely proportionate to the percentage of fats.

The meeting then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, JUNE 4TH, 1902.

Dr. T. R. FRASER, President, in the Chair.

Dr. G. A. GIBSON showed a case of "tabes dorsalis" with unusual symptoms. The patient was very ataxic, but though there was a history of previous lightning pains there was no sensory disturbance. The chief point of interest was the existence of an isolated paralysis of the left external rectus, without there being either the Argyll-Robertson phenomenon or optic atrophy. There were also curious psychical phenomena, of the

nature of transient attacks of delirium. In contrast to this case a second patient was shown in whom, notwithstanding the existence of undoubted ataxia, almost the only symptoms were absolute atrophy of the right disc and partial atrophy of the left.

Mr. CAIRD showed a case of "double enterectomy" for tuberculous stricture at one sitting in a male patient, who had suffered from gastric symptoms for six or seven years previous to admission to hospital. For three years there had been cough and other chest symptoms, and within the fortnight preceding admission, diarrhoea. There was found to be almost continuous abdominal pain, but physical examination of the abdomen was negative. From previous experience of such cases tuberculous stricture of the intestine was diagnosed, and on operation two were found which were removed successfully.

Dr. WILLIAM ELDER showed a case exhibiting "choreiform movements." The illness had begun after scarlet fever five years ago, with twitching first in the face, then in the arm, and then in the leg, and this had continued up to the present time. About eighteen months ago, curious grunting sounds, due to sudden contractions, of the diaphragm began, and were a great source of annoyance to the patient and his friends. The movements were partially under control. The diagnosis lay between a chronic Sydenham's chorea and paramyoclonus multiplex, most probably the latter.

Mr. ALEXIS THOMSON showed a patient who, three or four weeks after confinement, was seized with acute abdominal symptoms indicative of "purulent peritonitis." Laparotomy was accordingly performed, and an ovary and tube removed. An excellent recovery ensued, but ten weeks later acute obstruction set in, and at the second laparotomy multiple bands were found constricting the small intestine. These were divided with favourable result. The peritonitis was of gonorrhoeal origin, and it was the speaker's experience that in such cases the infection was much less severe than if one of the ordinary pyogenic cocci were the cause; the pus, in fact, was usually sterile. It was not probable that the bands causing the obstruction would again form.

The following card specimens were shown:—

By Dr. F. M. GRAHAM: Base of a skull in which there is absence of the right lateral sinus, &c.

By Mr. CAIRD: Intestine in which there is a double tuberculous stricture.

By Dr. HARVEY LITTLEJOHN: (1) Specimens illustrating compression of the brain from hæmorrhage. (2) Specimens illustrating the effect produced upon the hands and feet by prolonged immersion in water. (3) Uterus showing appearance in menstruation. (4) Uterus from case of abortion at the fifth month resulting from external violence. (5) Photographs of a case of drowning.

Dr. ALEXANDER BRUCE read a paper on

HÆMORRHAGE INTO THE SPINAL CORD DURING PREGNANCY,

an abstract of which will be found on page 648.

Mr. SHAW MACLAREN read notes of two cases of

INTRA-PERITONEAL SUTURE OF THE BLADDER,

which will be found on page 649.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, June 14th, 1902.

CHOREA.

M. COMBY spoke at the last meeting of the Société Médicale of the good effects of antipyrine in the treatment of chorea, provided it were given in sufficiently large quantities. For a child, *et. 10*, for instance, he would administer a drachm of the salt in the day, and for children above that age he increased that dose by ten grains for every year of their age. However, in order to avoid accidents (eruption, vomiting, anuria) the patients should be enjoined rest and drink abundantly.

There were, however, some forms of chorea that remained refractory to the antipyrine treatment. In such cases arsenic should be ordered at the doses indicated by one of his colleagues (already reported in THE MEDICAL PRESS AND CIRCULAR). He had not much experience with cacodylate of soda, but he was inclined to believe that it was not of great benefit, in any case in the patients on whom he had tried it, he did not perceive much benefit from its use.

SERUM OF TRUNECEK.

M. Merklen gave an interesting account of the treatment of the accidents attending arterio-sclerosis by the concentrated serum of Trunecek. He said it could be employed with advantage against the asthenia and hyperexcitability depending on insufficient irrigation of certain portions of the nervous system. The injections of the serum diminished also, and even suppressed the dyspnoea and the asthma of patients suffering from sclerosed arteries. He had obtained in three cases out of five the best results—in two cases where milk and digitalis had been tried for a long time without any benefit to the dyspnoea, and a third where cardiac asthma and Cheyne-Stokes respiration were very distressing.

The injections of the concentrated serum, like the large injections of artificial serum, act, doubtless, on the asthenia and hyperexcitability of the respiratory centre, which in arterio-sclerosis are produced either by arterial ischemia and heart weakness, or by renal and alimentary toxæmia. The serum of Trunecek was capable of rendering good service in the cases above mentioned.

M. Levi presented several patients who had suffered from headache, noises in the ears, tingling sensations in the limbs, insomnia, &c.; in a word, all the accidents having for cause an insufficient arterial circulation and who were greatly improved or cured by the serum of Trunecek. The agent was administered either subcutaneously or by the rectum (one to ten drachms of pure serum), or by the mouth. For this latter method, the speaker prescribed a powder composed as follows:—Chloride of sodium, 10 grammes; sulphate of soda, 1 gramme; phosphate of lime, 0.40; phosphate of magnesia, 0.40; carbonate of soda, 0.40; phosphate of soda, 0.30; divided into twelve powders or wafers. One powder was given daily to begin with, then two and three if there existed no symptoms of intolerance. The treatment lasted generally from a fortnight to three weeks.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, June 14th, 1902.

At the Medical Society, Hr. Görges communicated a note on

ASPIRINE AND DIGITALIS DIALYSATE.

Since the year 1900 he had exclusively used aspirine among the salicylic preparations, which had the great advantage of having little or no bye-effects. It could be given for long periods without setting up any disturbances. He had given as much as one gramme daily to an eight years' old child for three months at a time.

The indications for its employment were all rheumatic diseases, articular rheumatism, as well as affections of the serous membranes, neuralgias, &c. He had seen good

results, even in acute gout, as well as in minor chorea. In the latter disease he was in the habit of giving one gramme three times a day for five days, then making a pause of three days, and then again giving it for another five days, and so on. He had been very successful with this method of treatment.

The dialysates of Golaz were watery alcoholic extracts made from fresh digitalis plants in which the concentration was always equable. The dialysed digitalis had the advantage over other preparations of the plant that it was always of the same strength the year through, and the dosage was consequently more trustworthy. In children the dose was three to five drops three times a day, and for adults five to ten drops. The action was that of a good digitalis preparation.

Hr. Ewald confirmed the good results obtained with aspirine even in nervous conditions of all kinds. Its chief advantage was that even when large doses were given there were fewer by-effects than when other salicylic preparations were used. In articular rheumatism he reinforced the action of aspirine by an exclusively milk diet.

Hr. Senator also spoke very highly of aspirine.

Hr. Beckmann spoke on

ACUTE INFLAMMATION OF THE TONSILS.

He said the disease was well characterised. The inflammation might extend to the nose and then give rise to suppuration of the accessory cavities. If the tonsils were removed in a child with snuffles, they ceased at a stroke. In disease of the middle ear, the tonsils needed to be borne in mind and treated. He also attributed a number of cases of rheumatic paralysis to the tonsils.

In cases of recurrent rheumatism when the palatal tonsils were not diseased, he had repeatedly found inflammation of the pharyngeal tonsils and when these were removed the recurrence ceased. These seemed to be very important as regards the development of tuberculosis.

From these the tubercle bacillus got into the lymph-stream and were deposited in the glands. At the time when these developed at puberty the bacilli might break loose and set up tuberculosis.

The treatment of acute inflammation of the pharyngeal tonsils consisted in insufflations, removal of the secretions, and gargling. Operation was only indicated when there were ear complications. For the prevention of recurrences extirpation must be performed, but this ought to be radical.

Hr. Menzl has an article in the *Zeitsch. f. Hygein.* (39/31) on

THE CULTIVATION AND BIOLOGY OF THE TUBERCLE BACILLUS.

According to this observer, Hesse agar is a good soil for tubercle bacilli and is equal to ox-blood serum. The virulence of the bacilli continues even after months of cultivation on this soil. Neither increase nor diminution in virulence could be detected.

With this soil the tubercle bacilli from sputum increased considerably in a few days; in fact, the increase could be observed from the first day. The same with tubercle bacilli from urine sediment.

The accompanying micro-organisms of sputum and urine were checked considerably in the growth at first, but not so far that colonies of tubercle bacilli became

visible to the naked eye. There was, therefore, so far, no other method of separating tubercle from other bacilli than passage through animals.

Tubercle bacilli were killed by exposure for from five to fifteen minutes to a temperature of 65° to 70° C. Animals inoculated with the heated material did not become tuberculous. After heating to 50° C. for an hour and a half the bacilli still retained their virulence.

The *Monatss. f. Prakt. Dermat.* (34/3) contains an article on the

ÆTIOLOGY AND PROPHYLAXIS OF MERCURIAL STOMATITIS AND PROCTITIS

by M. Bockhart, of Wiesbaden. For years, the writer says, the best prophylactic against stomatitis had been tannin 50 per cent. in chlorate of potash tooth paste. But to achieve success not only the teeth but the gums all round must be brushed with a soft brush, the neighbourhood of the roots of the lower wisdom teeth being the chief corner for buccal bacteria to be left in. Mercurial stomatitis, he pointed out, was a bacterial disease. The reducing action of mercury injured the tissues and rendered them less resistant to the action of bacteria, so that these found conditions favourable to their development. The chlorate of potash by its high oxydising power paralysed the reducing action of mercury, and assisted the secretory processes in the mouth. In the writer's experience the use of the paste was also successful in preventing proctitis, as when used such large quantities of bacteria were not swallowed as would otherwise be the case.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, June 14th, 1902.

MALFORMATION OF THE VOCAL APPARATUS.

At the Gesellschaft, Fein showed a female patient, æt. 64, with a five-millimetre membrane extending between the vocal cords. The woman never had at any time an affection of the throat to cause any such morbid change, which gave credence to the assumption that it must be congenital, especially as there was no clinical symptom or accident to account for the abnormality.

In connection with this case he drew attention to another female patient who presented a similar condition, whom he had shown before the Society last year. After he exhibited the case he decided to operate on the endolaryngeal membrane by tearing it asunder. The membrane, however, reunited, and had finally to be treated by intubation, after which it again recurred, but was finally cured by constant repetition. The clinical symptom was severe hoarseness, which has since almost disappeared.

EPITHELIOMA AND RÖNTGEN RAYS.

Schiff brought forward an extraordinarily good example of treatment by Röntgen rays in the case of an epithelioma at the root of the nose. When the disease was cured he performed a plastic operation by taking a flap from the forehead to build up the nose.

Bethi remarked that he had had this case five months under his care, during which time he had scarified and cauterised the morbid growth without success.

Weinlechner asked how long the case had been under the Röntgen ray treatment, to which Schiff replied that the treatment did not exceed six weeks.

Schiff then showed a Finsen lamp, modified by Bang. The electrodes are composed of iron points which send out chemical rays; another advantage is that it only required six or seven ampères current.

Lang said that Finsen himself admitted that this lamp did not come up to his expectation, nor did it fulfil the required conditions.

EPITHELIOMA OF NOSE.

Weinlechner showed another case with epithelioma at the root of the nose, which he had excised and cauterised with chloride of iron. Subsequently necrosis of the frontal bone set in, opening up both the frontal sinuses. He thought he might venture to close the defect by a plastic operation.

Reiselsberg thought if the case were his own he would drain the sinuses into the nose, freshen the edges and apply a flap across the opening.

Weinlechner showed a female patient from whom he had removed a sarcoma about the size of a man's fist. The growth was situated below the inner half of the left clavicle. During the operation it was found necessary to resect the axillary artery and radial artery; about seven centimètres of the latter were removed, leaving total paralysis of the radial muscles. If the disease shows no signs of recurring he proposes next year to perform a neuro-plastic operation to restore the innervation of the radial muscles.

Weinlechner also showed a youth from whom he had removed a revolver bullet from among the small bones of the left hand with the best results.

RETROPERITONEAL GROWTH.

Stangl exhibited a man from whom he had removed a retroperitoneal tumour about the size of a walnut, which was situated on the inferior mesenteric artery. Its structure was rich in Zuckerkandl's organic organisms, as it took up the chromic acid colouring greedily.

Wiesel related the history of two similar tumours whose cells exhibited this chlorophile property in a very marked degree.

Biedl said this physiological reaction was a trustworthy diagnostic sign of the nature of the growth.

Zuckerkandl remarked that this chromic affinity in complex cellular tissues was to be found in many parts of the body as a physiological structure which probably was the origin of all these idiopathic tumours. The retroperitoneal tissues of the pelvis and the hypogastric plexus are common examples, and which are probably the origin of these tumours.

VOLVULUS OF THE SIGMOID FLEXURE.

Eiselberg demonstrated, by means of a pathological preparation, an extraordinary twisting of the distended bowel and sigmoid flexure.

He also showed a young man, æt. 23, who had received a stab in the left side of the neck wounding the common carotid, which was tied at the time, but after a few days paralysis of the opposite lower extremity set in with renewed bleeding from the ligatured vessel necessitating the retying of the vessel.

The paralysis at the present time consists of facial and hypoglossal paresis, with the upper and lower extremities affected. From the cases hitherto published of wounds to the carotid and subsequent tying 30 per cent. have ended fatally, 32 per cent. have suffered from

cerebral disturbances, while 56 per cent. recovered. Hemiplegia occurred in 11 per cent. of the cases.

CARBONIC ACID GAS INHALATION.

Kovács, of Buda-Pest, has just published his recent experiments on carbonic acid gas, which has been occupying the minds of several clinical observers of late. Kovács finds that insufficient breathing, or the inhalation of carbonic acid gas, lowers the freezing-point of the blood.

On the other hand there is an abnormal increase in the osmotic pressure of the blood favourable to the inhalation of the acid, as, indeed, its elimination, particularly when the atmosphere contains an unusual proportion, or the respirations are insufficient, which would allow of an accumulation in the blood if not quickly eliminated.

His observation on the clinical effects when inhaled show that it reduces dyspnoea, diminishes cyanosis, and lowers the pulsation fulness and rhythmic movement, but increases diuresis.

Continental Health Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

AIX-LES-BAINS.

AIX-LES-BAINS possesses many advantages as a health and pleasure resort, such as facility of access, beauty of position, and completed sanitation, abundance and uniformity of mineral waters, inherited aptitude of *doucheurs* and *masseurs*, great variety of entertainments, amusements and excursions; numerous hotels, pensions, and apartments to suit all preferences. It lies on a main line (the Mont Cenis) of Continental travel. By rail it is only half an hour from Chambéry (the ancient capital of Savoy), 1½ hours from Annecy (with "the gem of French lakes"), 2½ hours from Geneva, 3½ hours from Lyons (one of the most interesting and most neglected by tourists of French metropolitan cities), 8 hours from Paris, and 18 to 20 hours from London by several routes.

The situation of Aix-les-Bains is a most desirable one. Picturesquely located, 820 ft. above sea level, on a hillside 90 ft. above the pretty lake Bourget, in an Alpine country renowned for scenery and healthfulness, central for excursions of greatly varied interest, and possessing elegant casinos noted for the excellence of their musical entertainments, this small Savoy town (quite apart from its facility of access from all directions, and in addition to the superiority of its mineral springs and medical treatment) offers inducements to those seeking recreation and rest rarely found elsewhere. All the comforts and enjoyments of modern life are here, amidst sheltered rural scenes, yet in the vicinity of the grand mountain ranges and great glaciers of the Juras, the Chartreuse, Vanoise, Maurienne, Tarentaise, and Mont-Blanc Alps. Its sanitary arrangements (aided by the large overflow of sulphurous waters from the baths) are unusually complete, and it is plentifully supplied with pure water from the wooded heights of Révard. Its hotels and other accommodations (at prices to meet all requirements, luxurious or economical) are unsurpassed on the Continent. Yet after all these extraneous advantages, and after attributing to them all merits rightly their due, the high renown, increasing as the years roll round, of Aix-les-Bains rests upon

its mineral springs, upon the up-to-date scientific acquirements of its physicians, and upon the able administration of its baths.

The two Thermal Springs here yield daily over a million and a-half gallons of sulphurous waters; having a temperature varying between 110° and 115° Fahrenheit; showing 4° by Dupasquier's sulphydrometre; and containing, in addition to its sulphuretted hydrogen, carbonates of iron, magnesia and alumina, with traces of bromides and iodides. They also contain "Barégine," an organic substance peculiar to these Springs, which gives an unctuous quality to the massage. And some scientists claim that during massage with Aix waters electricity is palpably evolved. The indications for "a cure" at Aix are principally chronic rheumatism, rheumatoid arthritis, gout, chronic catarrhal affections, neuralgia and nervous diseases, sequelæ of rheumatic fever, infantile paralysis, hemiplegia, sprains, surgical operations, &c. For a long time gout was considered by many medical men as a contra-indication for Aix; but about forty years ago Drs. Despine and Vidal began to receive gouty patients, and since then, owing much to the publications of Drs. Macé, Blanc, Bertier, Brachet, Monard, and Forestier at Aix, and of Sir Alfred Garrod, Sir Dyce Duckworth, Sir Herman Weber, and others in England, the treatment of gout at Aix-les-Bains is becoming universally recognised and recommended. In his lectures given in September last, during the visit of the *étudiants en médecine* to the French spas, Dr. Gaucher "finally and definitely classified Aix among the health resorts of France, to which gouty patients may be sent." (See Dr. Blanc's pamphlet, "The Gouty at Aix-les-Bains," just published by Messrs. J. and A. Churchill, London.) (a)

The present treatment at Aix is to a very great degree external; baths, douches, pulverisations, humages, &c., its main features being the successful "Douche-Massage of Aix." Judging from the medical publications of the seventeenth and eighteenth centuries, diet-regimen and copious drinkings of these sulphurous waters have been less relied upon by the physicians in recent years than such dieting and drinking were in former times.

Dr. de Cabias, in his books on "Les Vertus Merveilleuses des Bains d'Aix en Savoie" (printed at Lyons in 1823 and 1888), laid much stress on the importance of preliminary purgatives; copious and regular drinking of Aix sulphurous waters (even at meals) prior to and during the bath-treatment; and gave minute cautions as to "what to eat, drink, and avoid" during treatment. Some of his "words of wisdom" are, perhaps, worthy of more attention even nowadays; such as, to prefer other months at Aix than that presided over by the canicule, and not to begin treatment immediately on arrival, not to hurry through treatment too rapidly, and not to rush away too quickly after "the cure" is nominally concluded. Now more even than in those days of "slower coaches," very much of the benefits to be derived from a course at Aix (as at other spas) is sacrificed by over-haste to begin treatment, over-hurry to get through

treatment, and over-restlessness to go elsewhere. Near Aix are excursions enough, of many and varied attractions, to richly repay an additional sojourn of several weeks. Those who wish to "go up higher" will find a very agreeably located and comfortable pension-hotel, about 1,200 ft. above Aix, at Pugny-Corbières; located on the side of Mont-Revard, and facing S.S.W. Corbières enjoys a sunny exposure and is thoroughly sheltered on the north and north-east by the Revard Alpine chain. It has regularity of climate, warm and soft atmosphere, freedom from mists, fogs, and (because of the evening mountain-breezes) dews.

A funicular railroad runs from the Aix Park to Pugny-Corbières, and then to the summit of Mont-Revard (about 5,200 ft. latitude), from which a magnificent prospect is obtained of the Savoy and Dauphiny Alps. On Mont-Revard is a good restaurant, and an hotel for convalescents.

Although quite a modern station (the earliest bath-building being a thatch-covered structure in 1857), the Springs and bath-establishment at Marlioz have become an increasingly important adjunct to Aix-les-Bains. Marlioz is less than a mile distant from Aix, and connected therewith by omnibus and tramway lines. Its mineral waters are cold, sulpho-sodic (57° F.) and slightly charged with iodine and bromine. They are administered chiefly internally; by drinking, inhaling, and pulverising; the special indications being pharyngitis, laryngitis, chronic bronchitis, and enlargement of the bronchial tubes, chlorosis, and anæmia. Dr. Forestier writes:—"They are most useful in diseases of the respiratory organs, from the simplest cases of angina to the most serious forms of disease of the bronchial tubes and of the lungs; and are wonderful for children liable to repeated bronchitis, or suffering from hypertrophy of the bronchial glands, which so often lays the foundation for tuberculosis of the lungs." Dr. Macé advises Marlioz waters for scrofula, rickets, goitre, syphilis, and the lymphatic; and adds, "all those whose profession calls for strong and continued vibrations of their vocal organs should go each year to the Esculape Spring of Marlioz, to recover and strengthen their voices."

The Saint-Simon Spring (situated a mile north of Aix) is another valuable adjunct to the Aix treatment. It yields a pure, limpid, perfectly aerated water containing "very little alkaline, calcic bicarbonate, and ozonised magnesia, and its effervescence of oxygen and nitrogen gases render it superior in some respects to the Evian waters." The St. Simon water is used both as an agreeable table-water and medicinally in cases of gout, rheumatism, kidney and liver troubles, and for all maladies resulting from deficient nutrition. Dr. Blanc classes the St. Simon water as "intermediate between the waters of Evian and Contrexéville;" and Dr. Bonjean recommends it for "gastric affections of an inflammatory chronic character, for stomachic evils of a nervous nature, and for lessening the formation of uric acid in gouty and rheumatic complications."

An inquest was held at Wolverhampton last week on the body of a young married woman who died under chloroform given preparatory to an operation for the relief of a puerperal abscess. In the report before us it is stated that only ten drops of chloroform had been given and the patient collapsed in three minutes. At this rate chloroform is more fatal than prussic acid *quod absurdum est*. The usual verdict was returned.

(a) He writes:—"In order that the treatment of gout may be complete, three conditions are absolutely necessary:—

"1. Apply the general or local douche-massage of Aix.

"2. Get the patient to drink a sufficient quantity of water to facilitate the solution of the salts contained in the organism, and to provoke their elimination.

"3. Prescribe a special alimentary diet, which is to modify the constitution of the patient and prevent the formation of uric acid as a cause of gout."

The Operating Theatres.

GREAT NORTHERN HOSPITAL.

DEEP ABSCESS OF THE ORBIT.—Mr. PRYTON BEALE operated on a girl, æt. about 20, who had been admitted suffering from an extensive inflammatory condition affecting the left orbit and the eyelids. The history of the case was as follows: The day before admission the patient was seized with severe aching pain at the back of the left eyeball. There was no history of any injury, undue exposure to cold, or any inflammatory condition of neighbouring parts, such as the ear, nose, mouth, or frontal sinus, but it was subsequently discovered that the girl had suffered from periodical attacks of pain at the back of the eye for the last eighteen months, and these appeared to have been subsequent to a severe attack of influenza. Upon admission the condition was as follows: Very marked proptosis, extreme oedema and venous congestion of the conjunctiva, great swelling and redness of both eyelids, and a considerable amount of lymphangitis of the left cheek; there was very severe aching and throbbing pain behind the eyeball, there was practically no impairment of vision, and the optic discs were normal. The girl's general condition was bad, sallow complexion, furred tongue, rapid pulse, temperature 106, but rigors were not present. At the operation an incision was made through the upper eyelid, and a probe passed along the roof of the orbit; this was then followed by a pair of sinus forceps, and when the point of these had reached the back of the orbital cavity, about a teaspoonful of pus was evacuated. The cavity was next washed out with boracic lotion, plugged, and hot fomentations ordered to be applied every hour. During the next three days the patient's general condition improved steadily, but on the third day she had a severe rigor in the evening, the eye by this time was practically normal, only a very little pus escaping from the wound; during the next two days the rigors came on more frequently and it was noticed that the patient had some pain and stiffness about the posterior cervical muscles, but there was no pain in the head or eyeball, the temperature was normal between the rigors, and the patient appeared to be doing fairly well; next day, however, the rigors became more frequent, and her general condition rapidly much worse. She was therefore anaesthetised and trephined as rapidly as possible just below the left parietal eminence. A considerable amount of blood-stained fluid was found in the arachnoid space, but no pus could be discovered, although a probe was passed to the base of the brain. Mr. Beale said the case was one of great difficulty, because the orbital abscess had already started at the back of the orbit, and it was quite clear that the septic infection had not travelled from without, that is to say, from any wound about the eye, from the middle ear, from the nose, *via* the frontal sinus or from the mouth; under these circumstances it was felt that the infection must have spread either from an acute basal meningitis, or from a cerebral abscess in or near the frontal lobe, but there was nothing to support this view, seeing that the patient had had no symptoms either of basal meningitis or of cerebral abscess until five or six days after the opening of the orbital abscess,

at which time the eye and orbit had practically become normal. The trephining was undertaken as a last resort, for although there were no symptoms of meningitis at this time excepting the rigors and slight pain and distress in the neck, it was obvious that the patient was becoming very rapidly worse, and as no cause could be found outside the skull, there was just a hope that trephining might reveal some inflammatory focus. It was important, he said, to observe that the optic discs were normal throughout.

The patient died twenty-four hours after the trephining, and at the post-mortem examination basal meningitis was found from the medulla as far as the sphenoidal fissure with a few drops of pus at the latter situation; the brain and all other organs of the body were normal. Mr. Beale believed that the case was one of chronic basal meningitis following influenza. For some reason which was quite inexplicable, this had suddenly become acute and suppurative in the middle fossa of the skull, and so had spread through the sphenoidal fissure to the orbit. Although it was impossible to find any cause of septic infection through the nose, mouth, ear, frontal sinus, or foramen lacerum medium, he thought the most likely hypothesis was a basal meningitis starting at the last situation. It was quite certain, he pointed out, that the condition was not tuberculous.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 18, 1902.

THE NOTIFICATION OF CONSUMPTION.

THOUGH the war against consumption may be said to have entered on an active stage, and though, in various countries, signs are not wanting to show that real progress is being made, we regret to find that in Ireland that progress is least perceptible. An examination of the report of the Registrar-General (Ireland) for the year 1900 shows that the total number of deaths from all forms of tuberculosis amounts to 12,848, and that 10,076 of these were caused by pulmonary tuberculosis. The death-rate

for phthisis equals 2.26 per 1,000 living, while the total death-rate from all causes equals 19.6 per 1,000. Such a state of affairs is sufficiently serious, but when we find that the rate per 1,000 for the ten years preceding 1900 was only 2.12, or in other words that the death-rate from this cause is rising and was higher in 1900 than in any of the ten years which preceded it, one is tempted to ask has the war against consumption begun in Ireland at all. There are no doubt peculiar difficulties in the way of sanitary reformers in Ireland, which are not found to the same extent in other countries, but these difficulties must be met and overcome if Ireland is not to be left hopelessly behindhand in the race for prosperity and health. Foremost among these difficulties we are inclined to place the unsatisfactory state of the various public health Acts, and the partial way in which even these confused Acts are made applicable throughout the country. The most pressing need from a public health point of view in Ireland at present is that the various sanitary Acts should be combined into one, revised, and that made compulsory in every district. It is pleasing to note that in spite of these difficulties public bodies are beginning to awaken to the danger of the present state of affairs and to demand that a remedy should be found. At a meeting of the Irish Trades Congress held a short time ago in Belfast the question of the prevalence of consumption and the high death-rate caused by this disease was under consideration, and a resolution, which we publish elsewhere, was passed calling on the sanitary authorities of the various towns and rural districts to take steps to check its ravages. This awakening of the interest of the lay public is one of the most hopeful signs of the times, and, if this interest can but be kept from lapsing into slumber, much-needed reforms are bound to follow. It is, however, very doubtful if in the present state of the law the sanitary authorities have any power to adequately deal with consumption, and this is one of the strongest reasons for the necessity for revision. The Local Government Board have decided that pulmonary consumption is not a "dangerous infectious disease" within the meaning of the Public Health Act, and, consequently, the provisions of the section of that Act dealing with such diseases are not applicable to consumption. We have always maintained that education of the people in the true nature of a disease is the most potent weapon which can be used against it, and, in education, example has a more powerful effect than precept. How, then, can people be expected to believe that consumption is an infectious disease, when they see that the teachers themselves are compelled to treat it as if it was not such a disease? Patients suffering from advanced consumption are permitted to mingle freely with healthy persons, are treated in the same wards of our hospitals with other patients "not so suffering," and yet they are asked to believe that the disease is highly infectious. If the infectious nature of the disease was obvious

and insistent, this anomaly in our practice might perhaps pass unnoticed; but it is not so, and the onset is so insidious and slow that there is little cause for wonder if many refuse to believe in the danger, and attribute the source of their illness to any other than the true cause. Before any real advance can be made, with the object of checking the spread of consumption, it must be authoritatively recognised and treated as an infectious disease. To do this, compulsory notification will be necessary, as well as the establishment of special wards in our hospitals and infirmaries for the treatment of hopeless cases and of sanatoria for those for whom there is a reasonable prospect of cure. To bring about such a condition of things, a large expenditure of public money will be necessary; but if this expenditure will save the great waste of valuable life which is at present caused by consumption, can it be refused?

SOME POINTS IN TEMPERANCE REFORM.

THE subject of temperance reform is one of perennial interest to the medical profession, inasmuch as no class of the community has a more constant and close opportunity of realising the evils wrought by strong drink within the four walls of the United Kingdom. Yet the wheels of reform drag heavily, and it is well from time to time both to inquire into the causes of that tardiness and to indicate the most promising paths of future progress. The present position of the reformers may be fairly estimated from the proceedings of the delegates at the recent annual meeting of the National British Women's Temperance Association at Birmingham. The four main points dealt with by resolutions of the Society were those of Local Option, Grocers' Licences, Sunday Closing and the Inebriate Acts. As regards local option it must be admitted that the particular method in question has been found to work more or less successfully in various parts of America, Canada and Scandinavia. The granting of drink licenses in a district being controlled by the local magistrates on State authority, it seems reasonable that the inhabitants of any given area should be allowed to decide whether and what number of public-houses they are to have in their midst. Where the matter is determined by a handful of magistrates it is hardly possible to believe that an undue pressure, indirect it may be and unconscious, is brought to bear by the powerful local brewing and distilling and drink-distributing trades. In other words, the advocates of local option desire to introduce into the State control of the drink traffic the great principle of popular control which has borne so much good fruit in other directions. Local option is a simple extension of the fundamental canon of the British constitution which asserts the inalienable right of the majority to govern. Licensing magistrates are not chosen by popular vote, but are appointed by Lords-Lieutenant of counties in virtue of various social and official qualifications. Stated in this way

the case for the upholders of local option seems to be unanswerable. As to its desirability there can be no doubt that to decrease the opportunities of drinking is proportionately to lessen the total consumption of alcohol. On the whole, therefore, local option may be supported as a rational, logical, peaceful and practical step towards a much-needed reform. As regards grocers' licenses it seems certain that their existence furnishes facilities to a certain number of women for obtaining secret supplies of drink. The Sunday trade in London occupies an anomalous position, when we consider the vast advantages that have followed Sunday closing in Scotland, Wales, Ireland and the Colonies, and a similar remark applies to the hour of closing at night. The fact of the matter appears to be that no Government has dared to face the adverse storm that would be raised by interfering with the huge interests of the drink trade in London. As to the Inebriates Acts the Association desires that in future any confirmed inebriate may be placed in a licensed retreat on a certificate signed by two medical men and a magistrate. Any attempt of that kind to acquire fresh powers over the liberty of the subject raises grave constitutional issues. It may be doubted whether Parliament would ever consent to abolish the voluntary element in the seclusion of habitual non-criminal drunkards. At the same time it must be admitted that the present Inebriate Acts need strengthening in many points, notably in the State provision of suitable establishments for the reception and treatment of chronic inebriates.

MONSTROSITIES.

THE interest which has just recently been revived in the rather uncanny subject of human monstrosity by the operation on the Radica-Doodica twins, opens up wide vistas of thought—embryological, surgical, historical, and even theological. The rapid growth and diffusion of embryological knowledge during the past half-century has removed the half-paralysing, mysterious awe with which the persons of such duplex specimens of humanity were approached—even by the physiologist and surgeon of the former centuries. The respective advantages of anaesthesia and antiseptics have effaced the difficulties of the prolonged tortures of a very complicated operation, and the special dangers of fatally septic complications which were so prone to supervene upon the opening of any of the closed cavities of the human body. Accordingly, the separation by M. Doyen of the xiphopagous twins must ever remain a historic incident in the progress of the human race. The anchoring-point of mutual attachment of the "xiphopagous" twins in this case was the direct union at the ensiform cartilage. The non-communication of the great serous cavities went a long way to minimise the danger of an essentially "heroic" surgical procedure. The portentous interest attached to all such freaks of nature, when the birth of every monster—human or other—was regarded as an "omen" a prophetic manifestation

of the impending wrath of Providence, has had the necessary effect of attaching to the occurrence of monstrous births a good deal of historical interest. And the hankering after the mysterious and inexplicable, which has always been so pre-eminent a characteristic of *homo sapiens*, especially in the uneducated stages of his evolution, has successfully popularised the most preposterous explanations of the genesis of prodigies of every type and class. The knowledge of this fact prepares us for the protest of Ambrose Paré (Johnson's English version, 1634): "And they are to be reprehended here againe, who affirme the cause of numerous births to consist in the variety of the cells of the wombe, for they feigned a woman's wombe to have seven cells or partitions, three on the right side for males, three on the left side for females, and one in the midst for Hermaphrodites or Scats: and this untruth hath gon so far, that there have beene some that affirmed every of these seven cells to have bin divided into ten partitions, into which the seed dispersed, doth bring forth a divers and numerous encrease, according to the variety of the cells furnished with the matter of seed; which though it may seeme to have been the opinion of Hippocrates, in his book *De natura Pueri*, notwithstanding it is repugnant to reason, and to those things which are manifestly apparent to the eyes and senses." The existence of such seven cells would furnish an approximate explanation of the popular belief in those credulous times of the existence of a seven-headed specimen of humanity. Those of our readers who are acquainted with the colossal encyclopædia of natural history of which the materials were collected by the devoted enthusiast Ulysses Aldrovandus, will remember the illustration of such a specimen in the magnificent folio which bears the title of "*Historia Monstrorum*." And the simultaneous birth of *seventy*—corresponding to the Hippocratic number of uterine compartments—is not unknown in the history of puerperal abnormalities. But a still more comprehensive provision must be made for the phenomenal number of 365! Camerarius tells us of a Countess Mathilde of Henneberg, who was begged for alms by a desolate widow who held a twin child on either arm. On being spurned with scorn by the lady, who was herself then (obviously) pregnant, the disappointed candidate prayed that her ladyship would bring forth at the next birth as many children as there were days in the year. Her petition was honoured: on the Friday before Palm Sunday of the year 1276, the Countess Mathilde was delivered, at the Abbey of Lisdunen, of 365 children, "of the bigness of chickens new hatch'd," half male, and half female—the odd one being a hermaphrodite! "These were laid in two Basins and Baptiz'd by Guidon, Suffragan to the Bishop of Utrecht, who named the sons *John*, and the daughters *Elizabeth*; . . . as soon as they baptiz'd, they all dy'd, with their Mother."

DR. F. W. HEWITT, Anaesthetist to the King, has been appointed Physician-Anaesthetist to St. George's Hospital.

Notes on Current Topics.

Inadequate Precautions against Fire.

THE terrible holocaust which startled the inhabitants of the Metropolis last week is only one of a series, for several such must be within the memory of even the younger among us. On each occasion an outcry is raised against the apathy of the authorities in not insisting on more ample precautions being enforced on employers with regard to providing the means of escape in the not unlikely event of fire. After a time the outcry subsides and matters go on as before. On this occasion the outcry has been directed mainly against the fire brigade which, it must be admitted, proved miserably incompetent for reasons which have not as yet been clearly elucidated. What is infinitely more important is that regulations should be made and enforced, obliging employers of indoor labour to provide reliable means of escape. Not only cught staircases to be made unflammable, which can be done at comparatively trifling cost, but alternative exits from the upper part of the building ought in every instance to be insisted upon. Something of the kind is provided for in the case of new buildings, but those already in existence, though they may be veritable death-traps, are allowed to remain unprovided. Such precautions are doubly necessary when the building is filled with highly inflammable material, as was the case with the premises of the General Electric Company, and we hope that the public will not allow attention to be diverted from the fundamental considerations by the red herring of a defective fire brigade, although incidentally the shortcomings of the latter are deserving of careful investigation.

Medical Certificates for School Children.

FROM time to time magistrates indulge in a scathing condemnation of the manner in which medical certificates are granted to excuse the attendance of children at school. Considering the peculiar circumstances of the case the wonder is that medical men are not more often imposed upon by parents. On the one hand we have parents and children ignorant of the exact meaning of the phenomena of disease, bringing pressure upon the medical attendant, on the other hand, with a view to non-attendance. Anyone who is acquainted with the maladies of children will understand how, if there be the slightest doubt as to the meaning of this or that symptom, a doctor would adopt the obviously wise plan of keeping the child at home for a few days. Take the case of a slight sore throat, which may perhaps be the early stage of scarlet fever or diphtheria. Not long ago Mr. Garrett, the magistrate of the South-Western Court, remarked that the loose way in which medical certificates were granted was perfectly scandalous. The cases that led him to utter that criticism were some in which children attended school for part of each day while they held certificates of exemption. Surely the "scandalous"

conduct, if any, was on the part of the parents who disobeyed medical orders and sent them to school. One child was certified to be suffering from "ulcerated tonsillitis," a condition which is certainly septic in origin, and most undesirable as an element in school life. We wonder if that magistrate would approve of the exclusion of ringworm from schools, or would he agree in the views of the inspectors who try to force such patients into attendance.

The Removal of Aldehydes from Whisky.

THERE is no doubt, that, as has been pointed out on various occasions, whisky is not simply alcohol, but that it differs considerably from it in taste, if not in other properties. It now appears that one cause of difference is the presence of aldehydes, and that to this the initially irritating taste and flavour of whisky is due. Sir Lauder Brunton some time since pointed out that the aldehydes only affect the good qualities of mature whisky by their disappearance, and that as some of the energy of maturation is devoted to bringing about this disappearance, it is probable that an initially de-aldehyded spirit will mature more quickly than one not so treated. Since then, the successful application on a large scale of a method for the artificial removal of aldehydes during distillation, has directed public attention to the question. In a recent article in a contemporary, Sir Lauder Brunton returns to the question and shows the undesirability of the presence of aldehyde, in a still clearer manner. He considers that at least one aldehyde—furfural—gives rise when taken internally to great cerebral excitement, and suggests that many of the worst phases of intoxication are due not so much to the ethylic alcohol itself as to the presence of by-products. If this is so there is no doubt that his final conclusion is an important one. That since aldehyde and furfural are not necessary for the production of whisky, from the point of view of the public health they ought to be removed. This is an important matter which deserves the consideration of distillers, who in the past have not paid the same attention that wine-producers have to the advances of science.

Proposed Memorial to Semmelweis.

It is pleasant to learn that, at last, an attempt is being made to erect a memorial to Dr. Ignaz Semmelweis, the founder of antiseptic midwifery. Already some £1,800 has been collected in various parts of the world, and before the list is finally closed the amount will be doubtless larger. If humanity in general had known all they owed to the labours of Semmelweis, and if they had known the difficulties which he overcame and the obloquy to which he submitted, a fitting memorial would have been raised long before this. Semmelweis found maternity hospitals a veritable plague spot, with a death-rate of 12.24 per cent., and by his own unaided efforts he so improved them that the mortality fell to 1.27 per cent. In spite of this, instead of being hailed as a great benefactor and reaping the reward he deserved, he was persecuted by the more

ignorant members of his profession, and hunted from his hospital, to finally die in a madhouse, and his great discovery lay forgotten for almost a generation. Semmelweis brought about this great reduction in the mortality of puerperal cases by insisting on students and others disinfecting their hands with chloride of lime before examining patients, as he clearly saw that the death of the latter was in most cases due to some poison brought from without. It is interesting to note that some twenty years before Semmelweis's discovery, Robert Collins, then Master of the Rotunda Hospital, had completely checked an epidemic of puerperal fever by temporarily closing the hospital and filling each of the wards in rotation with chlorine gas. From that time until the end of his mastership, a period of four years, he did not lose a single patient from this disease.

King Edward VII. Coronation National Fund for Nurses in Ireland.

At a public meeting held in Dublin on June 10th a resolution was unanimously adopted to the following effect:—"That the historic and auspicious event of his Gracious Majesty's Coronation Commemoration in this capital of Dublin, and throughout Ireland, be celebrated by founding a fund for the benefit of aged, sick, or disabled certificated female nurses working in Ireland, to be called 'King Edward the Seventh's Coronation National Fund for Nurses in Ireland.'" Lord Justice Fitzgibbon, in proposing the resolution, spoke of the part played by nurses in the late war. He personally knew the history of fifteen of those who left Ireland to nurse in that war. Eleven were volunteers who joined the Nursing Reserve; ten had survived, and one had laid down her life for her patients. No provision was made by the State or other organisation for sick or disabled nurses. It was a poorly paid, hardly worked, and perilous calling. Sir Francis Cruise, M.D., Sir William Thomson, C.B., and Mr. T. Myles, F.R.C.S., all gave the scheme their unqualified support. We trust that in the subsequent arrangement of the details of this admirable scheme, due attention will be paid to ensuring that every nurse who desires to share in the benefits of the fund in her old age shall have been a subscriber to it during her life. We are confident that in saying this we express the opinion of the heads of the nursing profession in Ireland, who would strongly object to the encouragement of improvidence which would result from any other system of pension.

French Medical Excursion.

THE annual excursion for medical men and students through the health resorts and watering places of France, organised by Dr. Carron de la Carrière, is arranged to take place between September 7th and 16th. This year the trip will comprise the Vosges and Eastern districts, beginning at Vittel and Contrexéville, thence to Bourbonne-les-Bains, Luxeuil, Plombières, Salins and Besançon. Foreign medical practitioners and medical students are admitted to share the special advantages accorded

by the railways, hotels, &c., and the cost of the entire trip, inclusive of travelling and hotel expenses from start to finish, is 200 francs (£8). Dr. Landouzy, Professor of Clinical Medicine at the Faculty of Medicine of Paris, will take charge of the scientific branch, and will, at each station, deliver lectures on the therapeutical properties of the waters, and on hydro- and balneotherapeutics in general. Those of our readers who may be disposed to avail themselves of this opportunity to visit a very interesting part of France will do well to communicate with Dr. Carron de la Carrière (2, rue Lincoln, Paris) forthwith, as no admission can be accepted after August 25th. We have, on previous occasions, expressed surprise that our own watering places are not brought more prominently before the notice of the profession, and certainly no more economical and effectual means of doing so than these instructive round-trips could be devised.

The Disruption of Victoria University.

LANCASHIRE and Yorkshire are deeply interested still in the question of the proposed disruption of the great federal University of the North. Liverpool insists on independency, Manchester claims the right of carrying on the work of the present University, and seeks to retain the old name. If Owens College obtains powers to form a separate university it will probably be known as the Victoria University of Manchester. But the third partner in the present form, Yorkshire College, Leeds, is strongly opposed to the disintegration of the Victoria University as now constituted, and is taking steps to petition the King in Council against such dismemberment. Convocation as a body have also strongly opposed disruption, and many of the best educationalists in the country are much opposed to a useless multiplication of small and necessarily feeble Universities. Meanwhile it is feared that the uncertainty regarding the future of Victoria University will prove detrimental to the best interests of its respective colleges, and certainly the present clash of opinions and interests is inimical to the highest interests of university training in the North of England.

Sanitary Provision for the Coronation.

EVEN a typical Cockney can hardly recognise his London in its present dress. Its landmarks are in great measure stowed away in ugly packing-cases. But all these disfiguring structures of wood are to be carpeted with humanity. The processional days of Coronation week will tax the strength and temper of the strongest and best, but to the feeble and aged they may bring serious results unless adequate provisions are made for meeting hygienic necessities and supplying physiological needs. The most elaborate arrangements are being made for promptly dealing with cases of illness and every form of accident, but we fear that much discomfort and even serious physical ill may result to many from the lack of adequate

conveniences, proper protection, and suitable nutrition. The hours of waiting in the open streets will prove periods of severe testing, especially to the very young and the aged, and we trust that means will be found for mitigating physical distress and protecting all from bodily ill.

Alcoholic Intoxication in Childhood.

THE pernicious influence of alcohol on child-life is now generally recognised. Both in this country and in other civilised lands efforts are being made to limit the possibility of the alcoholisation of the children. These are based on hygienic necessity. They are essentially prophylactic measures. Dr. Eugène Trousson's recent thesis on "L'intoxication alcoolique chez les enfants" is a valuable study on the scientific aspects of the case. His observations go to show that alcohol not only exerts a pernicious influence on the foetus during pregnancy but that if fecundation occurs during the alcoholic state the offspring is in danger of suffering detriment. He also shows that from an alcoholic nurse or suckling mother fatal intoxication may occur to the infant. Both directly and indirectly alcohol appears to be highly prejudicial to the healthy development of the body, and exerts a stunting influence on mental evolution. Dr. Trousson's thesis contains a short bibliography which should be useful to those interested in the study and protection of child-life.

Financial Position of the Medical Council (Irish Branch).

THE financial position of the General Medical Council is far from satisfactory, as is clearly shown in our report of its recent meeting. The number of students, and hence the amount of the registration fees, has fallen off, and expenses are increasing. A tolerably correct notion of the position of affairs may be obtained from the fact that at the last meeting of the Council a member proposed that in future members should forego their fees for attendance. Bad, however, as the position of the General Council is, it is considerably better than the position of the Irish Branch Council. The present system is largely responsible for this, in that it makes each branch primarily dependent on its own receipts, instead of being fed from the funds of the General Council. The result of this is, that while the English and Scottish branches have considerable sums to their credit, the Irish branch is dependent for its existence on an annual grant from the General Medical Council. It has now been decided to remodel this unworkable system, and, in all probability, in future all sums received by the branches will be paid to the credit of the General Council, by whom all expenses will then be met. An additional change will be made in the working of the Irish branch, in that the present office in Dawson Street will be abolished, and a Registrar appointed, who will be able to do the necessary work at a smaller salary, as he will also be free to undertake other business. We regret that it should be found necessary to abolish the Irish office, but manifestly there is no alternative.

The Medical Fees for Attendance on the late President McKinley.

It appears from the American lay Press that there have been many rumours flying about regarding the fees which were paid for attendance on the late President McKinley. According to some journals, the fees for which the medical men in attendance asked were considerably cut down, while other journals stated that there had been a controversy among the medical men themselves regarding their amount. We are glad to find that these rumours have been authoritatively contradicted by Mr. Milburn, to whom, in conjunction with Senator Hanna, the medical accounts were referred. Mr. Milburn states that—"It is unjust to the doctors to represent them as having rendered bills which were cut down, or as having asked for compensation which was not allowed, or as differing between themselves. I am not at liberty to give the figures which I sent to Washington. Those which are given in the *Enquirer* are not correct. That is all I can say." The figures referred to as having been given in the *Enquirer* are as follows:—Dr. Matthew D. Mann, 10,000 dols.; Dr. Herman Mynter, 5,000 dols.; Dr. Roswell Park, 5,000 dols.; Dr. Charles McBurney, 2,500 dols.; Dr. Charles G. Stockton, 1,000 dols.; Dr. N. W. Johnson, 1,000 dols.; Dr. Janeway, 1,000 dols.

Reform of the Female Inebriate.

IN 1900 the London County Council started their retreat for female inebriates at Farmfield. The report for 1901 has just been issued. The number of cases treated during the year was forty-three. Among much that is discouraging there are sound elements for hope. "After admission, when the immediate effects of excessive drinking wear off, and the true character of the women comes out, there is very little of real depravity. They show themselves susceptible to the finest influences, and the period spent in the reformatory marks, in almost every case, a real progress." Much time is spent in the garden and the field. Wholesome industry in the open air affords rational and effective treatment, from which much may be expected.

Medical Practitioners and the Sale of Scheduled Poisons.

THE irregularities which have characterised the conduct of open surgeries in Scotland have raised various legal questions, and we note with interest that in the report presented to the Glasgow Faculty of Physicians and Surgeons by their legal adviser, Dr. Hill, it is laid down that while it is quite legal for a practitioner's wife or maid-servant to dispense a prescription containing a scheduled poison the medicine containing such poison can legally be handed over to the patient or his representative only by the medical man himself. If this be good law it introduces an element of embarrassment into dispensing medical practice, at any rate in Scotland. It is reported that quite a number of open surgeries have been closed, and others, it is apprehended, will

follow suit. However disagreeable this may be to the proprietors there will be little difference of opinion as to the social advantage which will accrue to the profession by the elimination of this trading element.

The Oral Instruction of the Deaf and Dumb.

It is now thirty years since the Association for the Oral Instruction of the Deaf and Dumb opened its training college, and it is not too much to say that in the interval a very great improvement has taken place as the result of its propaganda throughout the United Kingdom and its dependencies in the education of this unfortunate category of persons. It is to be regretted that this useful work, which to such a great extent assists in making its pupils useful members of society, does not receive more generous support. To be deaf and dumb constitutes a disability fully as grave as deprivation of sight, yet the victims of the former infirmities, for some reason, do not appeal with equal force to the charitable, and this in spite of the fact that the training which this Association is the means of imparting is of far greater practical utility than the assistance that can be rendered to the blind. We note in the report that no dinner or festival in aid of the funds has been held since March, 1897, and it occurs to us that in view of our insular habits this may in part explain the inadequate attention which the Society has received at the hands of the charitable disposed.

City Ambulance Work.

THERE is much to be said in favour of the establishment of a trained ambulance corps throughout the great cities of the United Kingdom. At present the work of removing our dead and wounded fellow-citizens is carried out by the police, who are by no means generally provided with easy-running wheeled ambulances of modern pattern; indeed, in many cases they have nothing available for this purpose but a paltry hand litter, which is eked out should occasion arise by a passing cab. Some towns, notably Liverpool and Glasgow, have organised a street ambulance service which is worthy of general imitation on account of its convenience, humanity, and efficiency. By its means any unfortunate sufferer from any kind of accident, sickness, or other disabling condition can be at once removed to hospital, to say nothing of the fact of first-aid treatment that can always be administered by the ambulance men. There can be no doubt whatever that the establishment of such a corps in the metropolis and in other crowded centres of population would result in a great saving of human suffering, and to some extent also of life and limb. To be of substantial value the ambulance stations would have to be liberally equipped and distributed at fairly frequent intervals, and should also be connected the one with the other by telephone. The present moment, when a large number of St. John Ambulance volunteers have returned from South Africa, would be especially favourable for the establishment of ambulance services in our great towns.

The "General Servant."

ATTENTION has been recently drawn in a pointed manner to a most deserving class of the community by the announcement of her Majesty the Queen's intention to give a Coronation tea to 10,000 general servants. It has been further intimated, however, that the girls will be selected solely from among those on the books of the Metropolitan Association for Befriending Young Servants, the Girls' Friendly Society, and the Ladies' Association for the Care of Friendless Girls. Now, with all due admiration for the excellent work achieved by the three societies mentioned, it may be questioned whether the scheme of selection thus advanced will secure the recognition of the most deserving general servants of the metropolis. Applying the test of length of service it is clear that servants of old standing will not belong to any of the associations mentioned, inasmuch as the latter are intended for the protection of young girls whose lot is cast amid the manifold dangers and temptations of the modern Babylon. The nature of those risks to young girls is brought home to the hearts of the medical profession in a way that it is to no other section of the community. Surely it would not be impossible to hit upon some plan of selecting ten thousand worthy general servants who had been in one place, say, for two or three years. A letter signed by two responsible householders and a clergyman from personal knowledge would be sufficient guarantee of good faith.

Laundries and the Factories Acts.

THE inclusion of laundries within the jurisdiction of the Factories Acts has done a good deal towards strengthening that most useful branch of legislation. It is now possible to control the hours of labour, which formerly were lengthened to an extent that was simply scandalous. The time during which every young person is permitted to work in such an establishment is limited by the Act to sixty hours per week. Further, in order to forestall any attempt at evasion, the laundry proprietor is obliged clearly to state the times he has fixed and to abide by that selection. Last week a large laundry company was fined in a London police-court for employing a number of young persons beyond the specified hours. The factory inspector did not press for severe penalties, in spite of the fact that there were two previous convictions on record. The company escaped with the comparatively trifling fine of £11, but it is to be hoped that the publicity of this exposure will serve as a warning to other laundry proprietors. From the point of view of public health, a good deal remains to be done by way of the control of laundries by the sanitary authorities. There should be some system whereby the Medical Officer of Health should have full powers of dealing with workpeople in these establishments. During the present small-pox epidemic in London a number of cases of that disease have been traced to laundries. There can be no doubt that a considerable amount

of infectious disease is spread by the agency in question.

The Influx of Enteric Fever.

IT is clear enough that the experiences of the recent war in South Africa cannot fail to leave a lasting impression on the policy of the Army Medical Service. It may be advisable, however, to remind civilian authorities here at home in the United Kingdom that there are other than purely military risks arising out of the situation. Perhaps the most serious matter is the enormous importation of enteric fever patients that has been going on for the last two and a half years, and is likely to continue for some considerable time longer. It is a well-known fact that the specific bacteria of enteric fever continue to be discharged by a convalescent from that malady for weeks or even months after his apparent recovery. That fact is of direct practical importance when we consider the many hundreds of soldiers invalided home on account of an attack of that specific fever. These men are distributed over the face of the whole Kingdom, both in town and in country districts. Fortunately, the general sanitary standards throughout the country are sufficiently high to prevent any fear of disastrous outbreaks resulting on a large scale. It is not improbable, however, that the wholesale distribution of the *bacillus typhosus*, which we imagine has been going on for some time in the United Kingdom, must here and there give rise to small localised outbreaks. It must not be forgotten that enteric fever is still endemic, even in London, with its carefully protected and ample water supply.

The Cambridge Medical School.

CAMBRIDGE has been of recent years rapidly growing in popularity as a University centre for the training of medical students during the first period, or more theoretical, as distinguished from the clinical part of their curriculum. But Dr. Latham's recent indictment shows that the further development of the Cambridge Medical School is in danger of being hampered by a lack of business-like capacity in those who now to a great extent control affairs. The physiological department has always been considered one of the most important, but Dr. Latham shows that the absence of Sir M. Foster, who is relieved from duties for three years and a half, and yet continues to receive half his stipend, and the insufficient teaching now afforded, are serious drawbacks. It also appears that the anatomical department is but inadequately equipped with material for the study of practical anatomy. As many as eighteen students are occupied in the dissection of one cadaver, and in 1901 eighty-nine students absented themselves from the practical anatomy work who ought to have been there. We are all interested in the development of the Cambridge Medical School, and trust that the Senate will lose no time in looking into the matters which Dr. Latham has drawn attention to, and, if necessary, rectify all defects without delay.

An American Plan for Checking Hospital Abuse.

INASMUCH as hospitals are medical charities, intended for the relief exclusively of those who are unable to pay for medical care, it is plain that persons belonging to any other social class who avail themselves of the services of hospital physicians virtually obtain such services under false pretences. Dr. Fowler, of Brooklyn, has gone to the trouble of taking proceedings against a number of hospital patients belonging to the above category for the express purpose of checking a widespread abuse. Several of the defendants paid up before the cases came into court, but others resisted payment on the ground that Dr. Fowler, as a servant of the hospital, was thereby incapacitated from charging for his services. The fees varied from fifty to six hundred dollars, and in all the cases judgment was either given in favour of the plaintiff or there was an adjournment. Whether County Court judges in this country would be willing to assist in repressing hospital abuse is a point which may be doubted, but it would unquestionably be an excellent means of deterring unscrupulous persons from defrauding the sick poor by taking their places in our hospitals. Who will bell the cat?

A Strike of Medical Witnesses.

AT the last Suffolk Assizes, a lad was charged with indecent assault on a child of six, and the Judge's attention was called to the fact that there was no medical evidence, the two Bungay doctors having declined to examine the child when taken to them by the police on the ground that the fees allowed by the Secretary of State for attendance at the Assizes were altogether inadequate. The Chief Constable has communicated with the Home Office on the matter, and we may hope his representation will receive the attention it merits, otherwise the example set by our Bungay *confrères* is likely to be followed by other medical men to an extent which may seriously interfere with the administration of justice.

Heroinomania.

HEROIN, although it still ranks among our "new remedies," is not free from a fatal attractiveness, and already we have to recognise that it is capable of giving rise to a special form of "craving." M. Jean Leyna de la Jarrige, in his interesting thesis on "*Héroïne—Héroïnomanie*," clearly shows that heroin must be considered a most undesirable agent in the treatment of morphinomania. It has been strongly advised for this purpose, but it is well that those who are so using it should realise that they are in danger of adding to their difficulties, and that in all probability the last estate of their patient may be worse than the first. We sincerely trust that the medical men of this country will do nothing to further the spread of heroinomania in this country, but exert their influence in preventing the adoption of a habit which is disastrous to mind and detrimental to body.

Lumbago.

LUMBAGO, or pain in the back, it is hardly necessary to explain, is a symptom and not a disease. In its ordinary form it is a painful manifestation limited to the muscles of the back, which serve to regain or maintain the erect position, hence it is very apt to follow a strain or effort such as that involved by remaining standing in one position for an unduly long time. Very often the so-called lumbago coincides with, and is probably due to, some functional disturbance of the kidneys; indeed, pain in the back is always an early and prominent symptom of renal congestion. The precise significance of the pain can only be ascertained by further examination and observation. The rheumatic form of lumbago is a very distressing and obstinate affection, but except for the irksome disability which it entails has not much importance. That due to the kidneys, on the other hand, may pass off as suddenly as it has come, or it may prove to be the prelude of graver trouble, according to the degree to which the renal functions are disturbed.

The Midwives Bill.

THIS Bill, after many vicissitudes, has at last secured the final approbation of the House of Commons. It is admittedly a flagrant example of the so-called tentative legislation, and this is held by its supporters, and apparently by the Government, to excuse numerous shortcomings and to justify certain inconsistencies. The Bill does not profess to establish what may be called real midwives, *e.g.*, women who have received adequate training in their calling, and have afforded evidence of even a moderate standard of proficiency, nor, on the other hand, does it openly declare that its scope is limited to the organisation of a class of monthly nurses. The best that can be said of it is that the principle embodied in this piece of experimental legislation may, in years to come, provide the basis for further developments.

The Bacillus of Dysentery.

It is said that Dr. Merin, who is in charge of the branch of the Pasteur Institute at Saigon, has discovered a bacillus he considers to be the true cause of dysentery. Dr. Merin's work in conjunction with Dr. Yersin on Asiatic Cholera has been so excellent that further particulars of his discovery will be awaited with interest.

The Chesterfield Friendly Societies.

FOR some time past the Chesterfield and District Friendly Societies' Council and the Midland Medical Union have been discussing, through the medium of five representatives of each body, certain points relating to an increase in the fees of adult and juvenile members. Difficulties have now arisen, and the former body threaten to form a Medical Aid Association for Chesterfield. This means that the services of the present lodge surgeons who practise in the town and district will be dispensed with, and a medical man will be appointed by the friendly

societies to devote his whole time to the interests of their members. Even now, we trust some way may be found out of the difficulty by an exercise of tact, judgment and forbearance on both sides.

It appears that no less than 1,479 of the deaths occurring in the Highland crofting counties of Scotland were uncertified. The fact was admitted by Mr. Balfour who, however, was unable to promise that any legislation would be introduced to reduce this appalling proportion of deaths of persons not medically attended.

PERSONAL.

LORD ROBERTS has accepted the invitation to preside at the distribution of prizes to the successful students of St. George's Hospital Medical School in October next.

DR. PATRICK MURISON, Medical Officer of Health for the county of Sutherland, has been appointed to the important post of Medical Officer of Health for the Corporation of Durban, Natal.

DR. C. C. EASTERBROOK, Senior Assistant Physician at the Royal Edinburgh Asylum, has been appointed Medical Superintendent to Ayr District Asylum, Galloway, with 431 beds.

WE regret to learn that Dr. J. W. Washbourn, physician to Guy's Hospital and to the London Fever Hospital, who acted as physician to the Yeomanry Hospital in South Africa, is lying seriously ill at Tunbridge Wells.

DR. MITCHELL, of Southwaite, near Carlisle, has just been presented with an illuminated address, an album, a large solid silver bowl, and a purse of money containing £261 in recognition and appreciation of his services for thirty-four years in the district.

THE Asylums Committee of the County of London invite applications for the important post of Medical Superintendent of their new Asylum for Epileptics at Horton, Surrey. The age limit is forty, with salary commencing at £500; further particulars will be found in another column.

M. COMBES, the Prime Minister of France, belongs to the medical profession in virtue of a medical degree, although his energies have found scope in many other directions, literature and politics to wit. He has an engaging personality, and he is known to take the greatest interest in the social questions which are awaiting solution not only in France but throughout the civilised world.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

PRESENTATION OF THE JOHN USHER INSTITUTE OF PUBLIC HEALTH TO THE UNIVERSITY OF EDINBURGH.

THE formal presentation to the University of this Institute, recently described in these columns, took place on June 11th, in the presence of a large gathering of medical men and others, presided over by Sir William Muir, Principal of the University. Sir John Usher, the donor, described the circumstances leading up to the foundation of the chair of Public Health of which the Institute is a necessary complement. One

part of his speech deserves special note as bearing on the recent controversy between the Town Council and the medical men of the city in regard to reporting work. He said: "It was brought to my notice that the city of Edinburgh would require not an institute but a laboratory for their work in connection with public health, and I said to the architect, 'You had better make some provision for that,' which was done. I thought that in a matter of this kind the town and gown might work together very well for their mutual advantage, but that was not the opinion of all those who have the management of our town affairs. However, after full discussion, it was resolved to accept the gift, and I hope that their final decision may prove that they have made a wise one." It has all along been known that Sir John Usher has favoured the step the Town Council took in transferring the reporting to the University, and one cannot but sympathise with their desire to acquiesce in the wishes of one who has been, and whose family have been, great benefactors to the city in the past. No doubt many members of the Council felt in a difficult position in coming to a decision, and it will be well if the profession will loyally accept the existing state of matters, even though it was not of their choosing, and do their best to co-operate with the authorities in coping with the recognition of infectious disease. Sir William Turner, in moving a vote of thanks to the donor, read a letter, now of some historical interest, received from the late Lord Playfair, then M.P. for the University, in 1873. It ran:—"I am always jealous for the reputation of our University, and that it should keep abreast of public wants. Medical officers of health are now becoming a great requirement of the country, but with the exception of the diploma of Trinity College, Dublin—for State Medicine—there is no certificate of the qualifications of young medical men for their fitness to discharge such important duties as are involved in public health office. . . . Would it not be worthy of consideration whether the University of Edinburgh should put itself in advance of these rapidly growing requirements for the public service? A supplementary diploma for public hygiene would give a great advantage to your graduates who obtained it."

In consequence of that letter degrees in Public Health were instituted, and the first was conferred in 1875 on Sir James Russell, a former Lord Provost of the town. The proceedings terminated by the presentation of an illuminated address to Sir John Usher from the Students' Representative Council.

[FROM OUR OWN CORRESPONDENT.]

[We are not responsible for opinions expressed by our local correspondents.]

THE EPIDEMIC OF SMALL-POX.—The facts regarding the outbreak of small-pox, to which reference was made in this column last week, have at last been made public. It appears that since March 13th, twenty-two cases have been reported to the authorities. Of these, one has terminated fatally, and the other twenty-one are in the Union Hospital, seventeen being convalescent. It has proved exceedingly difficult to secure adequate isolation in the crowded buildings of the Union Workhouse, and great credit is due to Dr. Gardiner Robb and his colleagues for the energetic measures they have adopted, including re-vaccination of the inmates and officials, and frequent medical inspections. The want of proper accommodation is the fault of the City Corporation, as mentioned here last week. As is the wont of such bodies, it is now trying to atone for former dilatoriness by a great show of energy, and work is said to be proceeding day and night at a temporary hospital at Purdysbron, which will contain sixteen beds for males and sixteen for females. The inhabitants of that neighbourhood are protesting loudly at the idea of such unwelcome visitors—but no one seems to take much notice of their protests, the daily

papers telling them that "experience has proved that a well-conducted isolation hospital is very rarely a source of infection."

DR. MINCHIN'S TREATMENT OF TUBERCULOSIS BY GARLIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I have had frequent opportunities of carefully examining several of Dr. Minchin's cases before, during and after a course of his garlic treatment, I can endorse everything Dr. Minchin says in the current number of THE MEDICAL PRESS AND CIRCULAR as to the wonderful effects of this treatment in various forms and stages of tuberculous disease.

About two years ago Dr. Minchin told me that he was confident that he had discovered a germicide which was fatal to tuberculous bacilli, while it was perfectly harmless to the patient and to other tissues. With the painful memory of the numerous once highly-vaunted remedies for tuberculosis, which after a brief trial have been consigned to the well-merited limbo of oblivion, I received this assertion of Dr. Minchin's with natural scepticism. However, when nine months ago Dr. Minchin offered to take into the Kells Union Hospital any cases I chose to send in, as test cases, I gladly availed myself of his offer and sent him in several cases of well-marked tuberculous disease. Three of these cases I see are reported by Dr. Minchin in this week's MEDICAL PRESS AND CIRCULAR. As I did not know the nature of the germicide used by Dr. Minchin until I saw this week's MEDICAL PRESS AND CIRCULAR, I had no opportunity of otherwise testing its effects than by sending them into the Union Hospital and seeing them there while undergoing this treatment. Anyone will allow that the environments of a union hospital are hardly conducive to the rapid arrest and cure of tuberculous disease, still in every case the effects were simply marvellous. Effects which were proved by microscope, stethoscope, thermometer and weighing machine, as well as by the patient's appearance and feelings. The change was as rapid, as striking, and the convalescence in every way similar to that which usually follows any acute infective disease which has been accompanied with a state of high fever.

This appears to me to be the most satisfactory phase of the treatment, as it emphasises the fact, now so generally received, that tuberculosis is usually an acquired and not an inherited disease, and that when the bacillus, the cause of all the trouble, is killed, the patient will, as a rule, recover as he would after the elimination and death of the germs of either variola or typhus. I trust I am not over sanguine, but from careful observation of numerous cases I feel certain that further extended trial will prove that in the garlic treatment as discovered by Dr. Minchin we have at length a simple, safe, and cheap remedy for most forms of tuberculous disease. If this proves true Dr. Minchin will have made the greatest medical discovery of the age, and conferred on suffering humanity an inestimable boon.

I am, Sir, yours truly,
JOHN RINGWOOD,

June 7th, 1902. Late Medical Officer, Kells Union.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Minchin's communication, "The Successful Treatment of Tuberculosis and Lupus by Garlic," in your issue for June 4th, appears to me to be of great value, and a safe step forward in the dark and difficult region of the pathology and prevention of phthisis. Dr. Minchin uses garlic, both by inhalation and by the intestinal tract. He makes the important remark that "garlic is largely used by the country people throughout Ireland . . . it enjoys a reputation among them for curing coughs, when it is used as an infusion and mixed with whisky."

Empiricism, the expression of human experience, precedes, and is indeed a true part of science; the strongly expressed longings of a people for a special food should arouse our earnest attention. As an illustration I may cite that forty years ago, when I had charge of Natives of India, I found among them a passionate craving for "acid fruits," lime juice, tamarind, &c. At that period medical fashions in India very much debarred the use of fruit by Natives; but the Native was importunate, there was no resisting his earnest beseechings for lime-juice, tamarind, &c.; the instinct of the Native conquered medical fashion, and "acid fruits" were made rations in emigrant ships jails, &c. Similarly, the Native had a supreme longing for onions, and for garlic in his curry. These early experiences cause me to attach great importance to Dr. Minchin's observation of the longings of the Irish peasantry for garlic, and their faith in its value "for curing coughs."

During the past twenty-five years here, I have had a similar experience of the longing of præphthical cases for the onion. My plan has been to record every case of phthisis and præphthisis, especially noting the correlative facts of structure and function, of hereditary deviations of structure and function, of atavism, in such phenomena. You have often favoured me with space for the record of these generic views of phthisis; I now ask to be allowed to give a parallel confirmation of Dr. Minchin's experience; my experience is with the onion.

May I venture to quote what I published in *THE MEDICAL PRESS AND CIRCULAR* of May 28th, 1884: "Of all the subjective phenomena associated with phthisis, and often for a long series of years, in the præphthical, there are few more striking than the prevailing passion for onions. I could fill columns with the emphatic statements of patients as to their great craving for onions, and their thorough agreement with their digestion and system. Of those asked one hundred and seventy-nine had this desire, against thirty-four who had not, but such numbers do not convey at all the passion which many of the præphthical have for them. There is no other more marked craving of the system. Nature never speaks in vain; and I have no doubt that there exists some 'nascent' condition, some state of molecular 'energy' in the onion, which goes near to supplying the body with the true correlative for healthy growth. Such is the craving for onions in many of the phthical, and such their agreement with the system, that I do not doubt but that it is an instance parallel with that of the Swiss, who by some instinct, or insensibly evolved experience, ate burnt sponge to cure their goitre, or parallel to the passion of the low-fed Hindu for tamarind and lime-juice. . . . A plant to be in perfect health must have its elective essential elements in the soil; the amount may be extremely small, but that amount is all-essential to health, life, and 'survival.' The very smallest secular changes are the occasions or courses of the greatest operations in Nature, nor is the human body exempt from parallel laws."

The medical mind, to-day, is, I believe, too much commanded by the bacillus, as the "cause" of phthisis, overlooking the great biological orderly, wide and profound "correlations" of phthisis, correlations which extend back often to many generations, and involving structure and function; but I will not now repeat what I have portrayed on these subjects so often in your pages, my object being to emphasise the value of the direction of work in which Dr. Minchin is engaged.

I am, Sir, yours truly,

WILLIAM H. PEARSE.

Plymouth, May 12th, 1902.

HOSPITAL APPOINTMENTS.

To the Editor of *THE MEDICAL PRESS AND CIRCULAR*.

SIR,—The holding of more than one appointment either as Physician, Surgeon or Gynecologist to several hospitals is, I consider, most unfair to the profession.

Surely there are quite as able men in these branches who, through want of interest, coin, &c., are allowed to remain outside the pale (so to speak) while those hold-

ing duplicate posts cannot possibly give the same time or attention as if they held only the one.

In some provincial hospitals the rule of retirement at sixty years of age does not exist. This, I consider, is also an injustice to others who, perhaps, are quite equal if not superior in talents, and, being younger, are better able to perform the duties pertaining to the appointment, but who are thus excluded from office. Why nowadays (as in every other profession but medicine) merit should not come first I should like to know?

New blood should be transfused at intervals into every hospital staff, and would soon tell, by the reduction of mortality, shorter occupation of beds by patients, and the vast curtailing of expenses in proportion to the numbers relieved. How few men who have been appointed on the staff of any of the large hospitals could honestly say they had gained the position by merit alone I trow not.

I am, Sir, yours truly,

London, June 16th.

A. D.

THE PHARMACEUTICAL SOCIETY OF IRELAND AND LEGAL PROSECUTIONS.

To the Editor of *THE MEDICAL PRESS AND CIRCULAR*.

SIR,—The article in your issue of the 4th inst. having been brought under the notice of my Council, I am directed to assure you that the recent prosecutions by this Society could in no way be accurately described as "groundless legal actions," and to say that they were dismissed by the magistrate solely on the grounds of the form in which the summons was worded. The fact that the magistrate refused either of the defendants their costs would alone show that there were real offences against the Act in both cases, and so neither could be claimed as "legitimate trading." Many similar cases have resulted, both in Great Britain and Ireland, in convictions, and some have even received the stern attention of the General Medical Council.

My Council deeply appreciates the support you have at all times afforded them in carrying out the provisions of the Pharmacy Act, and they feel that your strictures were caused through reading a most misleading paragraph which appeared in the daily papers on the Monday following the decisions.

My Council consider that, as they have at all times engaged the highest legal advice obtainable, and entrusted to them the carrying out of the prosecutions, it is at least regrettable that the members of my Council should be charged with want of common attention when they are unsuccessful solely through the technical error in the framing of the police court summonses. While joining you in regretting the undesirable effect these technical defeats may have on the public, my Council are certain that in no way are they forgetting their position, either in regard to the safety of the public or in maintaining the legal rights of their licentiates.

I am, Sir, yours truly,

ARTHUR T. FERRALL.

(Registrar.)

[The two summonses to which we referred in our article were dismissed by the presiding magistrate on the grounds that they were brought against the wrong persons. Our comment that more care should be bestowed on the initiation of prosecutions was the result of this, and was written in no unfriendly spirit.—ED.]

DR. DOVER AND HIS POWDER.

To the Editor of *THE MEDICAL PRESS AND CIRCULAR*.

SIR,—I ask permission to supplement the interesting account you gave in your issue of May 14th of Thomas Dover, one of the pupils of the great Sydenham, by an account of a few less known incidents of his memorable voyage. And I would draw attention to the fact that Dr. Thomas Dover was selected to be the surgeon of the fleet because of the high reputation he had already acquired in his profession. The name "buccaneer," as applied to Dover, gives a wrong impression; neither he nor his companions were in any sense "filibusters" or buccaneers.

On the contrary, he was one of a body of gentlemen who sailed as privateers under commission from good Queen Anne; one of the heroes of the people that went from the banks of the Thames and the Avon and the Plym and the Dart, "self-taught and self-directed, with no impulse but what was beating in their own loyal hearts, went out across unknown seas fighting, discovering, colonising."

Dr. Thomas Dover sailed under his friend Captain Woodes Rogers, who in 1708 was called from being Governor of the Bahamas to be admiral of the little fleet of two vessels, the *Duke* and *Duchess*, that some patriotic inhabitants of Bristol had furnished and equipped to fight against the Spanish in the South Sea. Woodes Rogers sailed in the *Duchess*, and William Dampier, who had just published his memorable "Vindication of his Voyage to the South Sea in the ship *St. George*," was master of the *Duke* and pilot of the expedition. Rogers, it would seem, having no personal knowledge of the Pacific. Dampier, besides being a bold seaman, had also studied navigation as a science. Dr. Thos. Dover's official title was "Second Captain of the *Duke*, President of the Council, and Chief Medical Officer." The expedition sailed from King's Road on August 2nd, 1708, and after touching at Cork, steered for the Canary Islands. Rogers, a strict disciplinarian, suppressed a mutiny by having the principal offender flogged, and he as regularly conducted Divine service and required a religious life of his crew, as did Drake, who excommunicated a petty officer for swearing.

Off Teneriffe they captured a Spanish bark laden with wine, which they added to their own stores, and made for Cape Horn in the beginning of January, 1708-9. Here they encountered violent storms, and were driven as far south as 61° 53', and it was resolved to make for the Twin Islands—*Mas-a-Tierra* and *Mas-a-Fuera*—the former of which is known as Juan Fernandez, from the Spanish pilot who is credited with discovering it. On arrival Dr. Dover went on shore in a boat, and brought off a man dressed in goatskin and speaking English with difficulty, who turned out to be no other than Alexander Selkirk, who in 1703 had joined Dampier's Privateering Company, and was put on shore by Captain Thomas Stradling, with whom he had quarrelled, with a few books, his nautical instruments, a knife, boiler, axe, gun, powder and ball. Before the ship left he begged to be re-admitted, but Stradling refused, with the curious result that Selkirk became a hero for all time.

Dampier at once recognised his old shipmate, who was a good seaman, and as such was welcomed by Rogers and appointed mate of the *Duke*. After refitting at Juan Fernandez, they cruised off the coast of Peru for some months, capturing some small vessels and one larger one, in attacking which Thomas Rogers, a brother of the admiral, was killed by a shot in the head. They then sailed for Santiago de Guayaquil, and sacked the city, an operation which Dampier had performed some three years previously. On December 21st, 1709, he captured a Spanish treasure ship off the coast of California, in capturing which Rogers got a bullet-wound in the mouth which smashed his upper jaw, the bullet being extracted six months afterwards, presumably by Dr. Dover. They retained the vessel as a prize. Dr. Dover was placed in charge, with Alexander Selkirk as his sailing master. On December 27th they sighted a rich Manila treasure-ship bound for Spain; the *Duke* and the new prize, now named the *Marquis*, were becalmed, but the *Duchess* attacked the Spaniard, who proved a Tartar, for she beat off the *Duchess*, and later on both the *Duke* and the *Marquis*, and sailed away with the rich cargo of silver ingots. In this fight Rogers had his heel bone shot off and his ankle broken—the principal medical officer of the fleet held no sinecure. Since they left Santiago de Guayaquil the men had been suffering from an epidemic of a dysenteric character, supposed to have been due to the bad water they had shipped, and for which Dr. Dover prescribed his celebrated powder.

This outbreak of disease decided Rogers to seek Guam

in the Ladrone, then, as now, celebrated for its abundant and pure water; there they refitted and rested the crews. Hence they sailed for Batavia, where they took in provisions, and started on their voyage to round the Cape of Good Hope, which they successfully accomplished on December 27th, and arrived in the Downs on October 1st, 1711. During the return journey the epidemic of dysentery so occupied Dr. Dover's time that Rogers appointed the mate of the *Duchess*, E. Cook, captain of the *Marquis*, to allow of Dr. Dover giving his undivided attention to the sick. How well he performed his professional duties is shown by the fact that during the voyage there was not a single death from scurvy.

Selkirk's share of the spoils of war was £800, a large sum in those days, Dover secured considerably over £10,000, and Rogers was commissioned by Robert Walpole as Captain-General and Governor-in-Chief of the Bahama Islands, where he died at Nassau on July 16th, 1732.

Soon after the expedition returned Selkirk was introduced to Sir Richard Steele, who made his life in Juan Fernandez the subject of a paper in the *Englishman*. This paper is said to have been the source of Defoe's inspiration for his classic "Robinson Crusoe." Dover settled down in practice in London, and increased his wealth and reputation by his wonderful powder, the history of which I may some day find time to give, and late in life took to writing. His "Treatise on Mercury" appeared in 1733, and in the same year his "Ancient Physician's Legacy," which called forth a rejoinder, "Physical and Physiological Remarks on Dr. Dover's late Pamphlet," by H. Bradley.

I am, Sir, yours truly,

GEORGE FOT.

Dublin, June 9th, 1902.

Literature.

PRACTITIONER'S HANDBOOK OF DISEASES OF THE EAR. (a)

WHATEVER doubts we may have entertained in our mind as to the advisability of collaboration in the writing of a practitioner's handbook are set at rest by the perusal of the work before us. It is an excellent example of a method, the chief danger of which lies in the fact that specialists are apt to become discursive. Happily, this danger has been avoided, and the object, set out in the preface, to be "simply what its title indicates: 'A Practitioner's Handbook,'" has been achieved.

Dr. Macnaughton Jones is personally responsible for a good many of the chapters, and it is hardly necessary to add that the work is well done. *En passant*, we are glad to note that in his short introductory chapter he gives full credit to the late Sir William Wilde, of Dublin, as being a pioneer in the then neglected field of otology.

In future editions we should like to see stress laid upon one minor point, and that is the use of an aural probe bent at an obtuse angle, as the use of straight aural probes necessarily occludes any view of the meatus, &c.

Dr. Milligan and Dr. Tilley have contributed excellent chapters upon the complications of chronic suppurative middle-ear diseases and diseases of nose and nasopharynx in their respective relation to ear symptoms. A special word of praise must be given to the chapter on the anatomy of the ear by Professor Birmingham and Dr. Joyce. Dr. Dudley Buxton, in a chapter of six pages, tells a general practitioner all that is necessary for him to know regarding the proper anæsthetic to use in nasal and aural cases. And this short chapter may be taken as typical of the whole book, in that it contains

(a) "The Practitioner's Handbook of Diseases of the Ear and Naso-Pharynx." By H. Macnaughton Jones, M.D., M.Ch., F.R.C.S.I. and Ed.; W. E. H. Stewart, F.R.C.S.Ed.; W. Milligan, M.D., C.M.; Herbert Tilley, M.D., B.S., F.R.C.S.Eng.; Ambrose Birmingham, M.D., F.R.C.S.I., F.R.U.I.; and Robert Dwyer Joyce, F.R.C.S.I., M.B.C.S. Sixth Edition. Pp. xv. and 308. Illustrations 182 and Seven Plates. Price 10s. 6d. net. London: Ballière, Tindall and Cox.

all that and no more than a general practitioner should but often does not know.

In conclusion, we should like to congratulate Dr. MacNaughton Jones most heartily on the excellence of the work for which he is responsible, and to which he has himself so largely contributed. The publishers also deserve considerable credit for the manner in which the work is turned out.

MAY ON DISEASES OF THE EYE. (a)

THIS manual has undoubtedly met with considerable favour, inasmuch as a second edition has been called for within the short period of eight months. Its success has been well deserved since, as a concise, practical, and systematic handbook on diseases of the eye it may be said to be one of the best. The author has been at great pains in the revision of this edition, and has added new illustrations, seven plates, and eight pictures of the fundus, showing the common diseases thereof. These new features have greatly enhanced the practical value of the work, without appreciably augmenting either its bulk or cost. Except in the passages which have come under revision, the text remains the same as in the previous edition; a further detailed criticism of the work, therefore, on this occasion is uncalled for. We may, however, add that both students and practitioners will find this manual exactly suited to their requirements so far as a handy volume of diseases of the eye is concerned. In this respect it admirably fulfils its *raison d'être*, and we cannot do more than cordially recommend this new edition.

QUAIN'S DICTIONARY OF MEDICINE. (b)

In this, the third edition, of the colossal undertaking initiated by that indefatigable worker, the late Sir Richard Quain, various modifications have been introduced on lines which must have suggested themselves to those who have made much use of preceding editions. Articles which, as the Editor observes, were excellent in themselves, but not in accord with the special object in view, have been judiciously omitted, overlapping has to a great extent been eliminated, while the pruning knife has been skilfully used for the removal of discursive or otherwise superfluous matter. Thanks to the economy of space resulting from this process of emendation it has been possible to find room for a considerable number of new articles, in addition to amplifying and, in some instances, rewriting, pre-existing contributions; and in spite of this literary hyperplasia the publishers have managed to comprise the compilation as a whole in a single portly volume. This volume, it is true, comprises close upon two thousand pages of solid type, so that the writers have not necessarily been cramped.

We have made a leisurely survey of the work, selecting for examination subjects which happen to have come more or less prominently into notice in the medical journals or at the medical societies, with the object of ascertaining the degree to which the matter has been brought up to date. We carry away from this critical review a highly favourable opinion of the ability and thoroughness of the contributors, together with genuine admiration for the editorial direction which has succeeded in welding the various contributions into a homogeneous and harmonious whole. Nowhere are we able to point to noteworthy errors of omission, still less to errors of commission.

It is, of course, a disadvantage to be restricted to the views of an individual contributor instead of being presented with a synopsis of contemporaneous views on a given subject, though individuality has its merits as well as its drawbacks. The disadvantage is obvious in

respect of such a subject as general anaesthesia, which in this instance, is dealt with at sufficient length by Dr. F. Hewitt. The author is known to prefer the use of a mask for the administration of chloroform to that of any "regulating" inhaler, but the reasons which he gives for the preference are far from convincing. The mask, he says, is less likely to permit of injury of the skin by chloroform, but the fact remains that the only instances of "chloroform burns" in our experience have followed the use of a mask or similar appliance. In any case no such advantage can be claimed for the mask as against Junker's inhaler, since an accident of the kind has been rendered actually impossible with the latter. The author gives no statistics of the mortality of the ordinary method as compared with that of a regulating inhaler, otherwise, no doubt, his figures would contradict his conclusions.

The volume is embellished by the insertion of twenty-one full-page plates, fourteen of them being in colour and of distinct excellence, and there is no lack of illustrations in the text elsewhere. The "Dictionary" is a medical library in itself; the information it gives, though condensed, is complete, and it is obvious that brevity has not been the only, or even the first, consideration of the authors.

PROBLEMS RELATING TO SURGICAL OPERATIONS. (a)

THIS volume, which is an essay awarded the Alvarenga prize for 1901 by the College of Physicians of Philadelphia, is a very interesting account of a series of experiments carried out on animals (mostly dogs) with the view of throwing light on the effects: 1, of severing and of mechanically irritating the vagi; 2, of intravenous infusion of saline solution; 3, on the physiological action of cocaine and eucaine; 4, on the effect of temporary closure of the carotid arteries. These experiments were evidently all carried out in a masterly way, they are described in simple and intelligible language, and each of the four divisions is followed by a summary of experimental evidence which of itself is most instructive, besides being supplemented by clinical application on the human being. The work, we should imagine, will be eagerly read by physiologists, and ought to be of great interest to all surgeons.

INFECTION IN MILITARY SURGERY. (b)

THIS practical and interesting work deals with the terrible effects of infective germs in wounds received during warfare; the authors lay stress on the fact that both the suffering or the death of the wounded is brought about more as a consequence of the disorders caused by infective germs than as a result of the traumatism, the effect of the projectile. They start with a symptomatic division of wounds into those progressing without and those progressing with infection. The first chapter treats of the infection of wounds in warfare and is divided into three parts—(1) the nature of infective germs; (2) the mechanism of the production of infection; (3) the more or less favourable form for the reception of the germs in the organism. Chapter II. takes the reader through the evolution of those bullet wounds which are either very slightly or not at all infected by germs. Chapter III., comprising 100 pages, is devoted to the consideration of those bullet wounds which have become contaminated by infective germs. Both these chapters deal successively with the lesions of the soft parts, of the arteries, veins, nerves, bones, and joints. The next four chapters are respectively on pyæmia, septicæmia, tetanus and hospital gangrene, all being considered from the point of view of military surgery.

Finally, the last chapter treats of the various foreign bodies, including the projectile itself, which may be introduced into the tissues by a gunshot wound, and

(a) "Manual of the Diseases of the Eye. For Students and General Practitioners." With 273 original illustrations, including 36 coloured figures. By Charles H. May, M.D., Chief of the Clinique, and Instructor in Ophthalmology, Eye Department, College of Physicians and Surgeons. Second Edition, revised. London: Baillière, Tindall, and Cox. 1902.

(b) "Quain's Dictionary of Medicine." Edited by H. Montague Murray, M.D., F.R.C.P., Joint Lecturer on Medicine, Charing Cross Hospital, &c.; assisted by John Harold, M.B., B.Ch., Physician to St. John's and St. Elizabeth's Hospital, &c.; and W. Cecil Bownquet, M.A., M.D., M.R.C.P., Physician to Out-patients, Victoria Hospital for Children, &c. London: Longmans, Green, and Co. 1902.

(b) "De l'infection en chirurgie d'armée." Par Drs. A. Nimier and Ed. Laval, Pp. 398. Paris: Felix Alcan. London: Baillière Tindall, and Cox.

remain *in situ*. The authors refer to various experiments that have been made to determine the condition of these bodies after a lengthened sojourn in the economy. It is impossible, in a necessarily curtailed notice, to do justice to the merits of a work such as the one before us, or to specify any one chapter as being specially interesting and instructive; suffice it to say that the whole book is interesting and instructive, the writing being concise and simple, the references to other works short and to the point, the accounts of the military surgery and its failures in different campaigns of various nations never wearisome; in fact, the work should be in the hands of every Army surgeon, and it seems a pity that no translation of it into English is available.

BROOKS ON THE ELEMENTS OF MIND. (a)

A TITLE of this kind over the name of an author unknown to us at once excites a feeling of apprehension akin to dismay. Nor is that feeling diminished on learning that the work is "an examination into the nature of the first division of the elementary substances of life." The author owes his inspiration to "a fortuitous train of thought" which enabled him to discover the elements of mind. These, when compounded with those of Force and Matter, constitute "the mysterious substance we call life." The use of this word "substance" to express a quality, or function, which is life, warns us that the author is either going to use a vocabulary of his own or intends to invest familiar words with a significance of his own creation.

His first original (?) observation is that vices and virtues differ not so much in kind as in degree, so that virtue may under given circumstances become a vice and *vice versa*. Well, that is hardly an acquisition to our knowledge, and had our author read even a little he would not have been at the pain of discovering the platitude.

Let us, however, plunge into the vortex. The author describes his theory as the "Greater Mind Theory," which, when asked to explain, he says is "simply a new name given to well-known mental and physical phenomena exhibited in a greater or less degree by every kind of organism, whether animal or vegetable. . . in fact, all the imitative forces in life, whether they be those of mind, matter, or of physical force." Reserving judgment with regard to the *G. M. T.*, we proceed, but we stumble on the *Ego* and the *Greater Ego*. *Ego* apparently is John as he sees himself, the *Greater Ego* being John as he appears to his Maker, though the term elsewhere seems to mean "life in the abstract."

Now, we set out with the firm intention of criticising, hostilely if possible, the author's theory, and in order to find out its weak points we have waded through or stumbled over page after page of verbal quibbling without succeeding in obtaining any tangible criticisable idea of what the author is aiming at. There is abundant evidence of long and painstaking reflection, of sustained introspection and of extraordinary agility on the part of the author in shifting the position of the point under consideration as soon as the reader is brought close to it. What the theory is we know not; it eludes our grasp, we cannot even "see as through a glass darkly." Our impression is that the author is the victim of a big idea to which he is unable to give technical expression. There may be something behind his prose, but there does not appear to be anything in it—and there we must leave him.

HOLLANDER ON THE REVIVAL OF PHRENOLOGY (b).

THIS well-printed octavo of 512 pages contains a very interesting collection indeed of facts and arguments relative to intellectual localisation in the organ of mind.

(a) "The Elements of Mind" By H. Jamyn Brooks. London: Longmans, Green, and Co. 1902.

(b) "The Revival of Phrenology, the Mental Functions of the Brain: An Investigation into their Localisation, and their Manifestation in Health and Disease." By Bernard Hollander, M.D. (Freiburg, I.B.), M.R.C.S., L.R.C.P. Lond. London: Grant Richards; and G. P. Putnam's Sons, New York. 1901.

The authors of the fruitful researches which decided the topography of the motor centres in the cerebral cortex with approximate accuracy did not, for the most part, appear to have developed much faith in the existence of corresponding centres of intellectual power. And the observers, who professed such scientific credence, have, for the most part, displayed strangely contradictory opinions as to the geography of such centres. To find the majority of the professional public fondly believing that the frontal lobes were the chosen seat of the intellectual functions, while a few physiologists emphatically express their confidence in the view which places them at the opposite pole of the cerebrum, awakes some distressful recollections of the hopelessly vagrant opinions of the medical contemporaries of Bob Sawyer and Benjamin Allen. We consider ourselves deeply indebted indeed to the author for the mass of instructive evidence which he has collected—with the laborious care of an enthusiast and the judicious skill of an experienced master—on this very important and very interesting subject.

Dr. Hollander has also performed a noble duty in this volume—by constituting himself a minister of tardy justice to the memory of the great physician and physiologist whose enthusiastic life labours laid the foundation of our knowledge of the "Foundation of the Brain." To the ordinary educated man—even to the average medical practitioner—Gall is known merely as the foolish "system" of phrenology. A few, better-read than the majority of the professional public, know that he used to go to church every Sunday, and sit in the front seat of the gallery—not for purposes of devotion, but to observe the heads of other members of the congregation; and that he first localised the "bump" of veneration by observing that the most obviously religious always presented a notable elevation of the bregmatic area of the skull. But they are entirely unaware of the fact that Gall's great work on the anatomy or physiology of the brain remained practically unopened, and still constitutes a vast mine of information on its subject. A case of aphasia was placed on record by Gall nearly a century ago.

The vast series of facts and arguments collected in this volume are far too numerous to be even glanced at within the limits of a review. We must, accordingly, recommend all our inquiring readers to make themselves acquainted with its contents. We feel sure that they will be well rewarded for their trouble.

HOOD ON THE TREATMENT OF INJURIES. (a)

WE have carefully read this little volume, and have found it to contain much practical information. The late Mr. Hutton, the well-known bone-setter of thirty years ago, was not a medical man, but he attempted to cure surgical injuries, with the assurance of a "Modern Sequah," by means of what he called "The Secrets of his Art." He, it must be remembered, was entirely unacquainted with anatomy and surgery, but nevertheless he undertook to treat every case of injury and ankylosed joint that came before him, setting up passive motion where frequently qualified surgeons of repute would hardly dare to meddle, and when he restored motion by forcibly and suddenly breaking up adhesions produced by immobility he invariably told the patient and his friends that the case had been mistaken, and by his manipulation he had replaced "a little bone which was out of its place." Often he was successful in his treatment in restoring motion in a joint. But at best he was only a quack, and if he did harm by his manipulations he got a "quack's pardon."

We are therefore glad that Mr. Wharton Hood, who is a fully qualified medical man, and who appears to have devoted special attention to these forms of injury for many years has given the result of his experience to the profession, and has apparently rescued this class of practice from the region of quackery and placed it on a scientific and surgical basis. He divides his subject

(a) "The Treatment of Injuries by Friction and Movement." By Wharton P. Hood, M.D., St. Andrews M.R.C.S., L.S.A. London: Macmillan and Co., Limited. 1902. Pp. 182. Price 4s. 6d.

into eight chapters, and mentions the following among others: Injuries in general, individual fractures, individual dislocations, sprains, laceration of muscle, muscular exercises, conclusions.

Anyone connected with accident insurance companies knows full well how grossly dishonest some of the reports they receive are, and what impositions are practised on such companies from time to time by many who ought to know better. In the most trivial accidents the most aggravated accounts of the injuries invariably reported to be present is given in order to ensure a maximum amount of compensation.

If the little work before us assists even in a small way in producing a limitation of these dishonest and fraudulent reports of injuries received, the author has not written in vain, and we think the book will be largely consulted.

PROUST ON NEURASTHENIA. (a)

By many of our readers this not too elaborate monograph on neurasthenia will be welcomed for the simple reason that the subject is, as a rule, scurvily treated in text-books of general medicine. The remarkable lucidity and charm of the original have tempted the author of the English edition to attempt a translation which, unfortunately, fails to reproduce these qualities. The translator's sins are of omission, not of commission, that is to say, he translates accurately enough the sense of the original, but he does this in a form which, as not unfrequently, baffles the reader, especially one who is not familiar enough with the French language to guess the original phraseology. In spite of these blemishes the work may be commended to the notice of practitioners desirous of guidance in the recognition and treatment of a very difficult class of cases. The subject is admirably treated, and the advice given is sound. We may add that the work is clearly printed, and attractively turned out.

YEARSLEY ON ADENOIDS. (b)

It is remarkable that no monograph on the subject of adenoids has appeared in the English language before the one now under consideration, for it is over thirty years since Hans Wilhelm Meyer called attention to this important and by no means infrequent condition. Mr. Macleod Yearsley has filled the gap in an eminently satisfactory manner. After a short historical introductory chapter, he discusses the etiology of adenoids in a clear and instructive fashion. We are glad to find that he does not accept as etiological factors all the anatomical and pathological peculiarities that are met with from time to time in association with adenoids; and we fully concur with his remark that many of them should properly be transferred from the category of causes to that of results. It is probable that the same line of thought would apply in some measure to tuberculosis. Mr. Yearsley points out in the chapter on Symptomatology that "by their interference with proper nasal breathing and the consequent tendency that they exert to respiratory troubles, adenoids are a potent factor in the predisposition to phthisis." The remark met with in text-books that adenoids are found in cases of struma, would no doubt be equally correctly expressed by saying that struma is met with in cases of adenoids. In the chapter on Anatomy and Pathology, Mr. Yearsley very properly attacks the partial fallacy that adenoids disappear at the time of puberty; and explains that the greater facility in breathing sometimes met with at this time is due to enlargement of the nasopharynx rather than to atrophy of adenoids. In the excellent chapter on symptoms and complications, which forms about one-third of the whole book, the author is at his best, and not only medical practitioners but parents and school teachers would undoubtedly benefit by its perusal. The various operative procedures for the removal of adenoids are then clearly described, and the book concludes with

a very useful chapter on Anæsthesia from the pen of a recognised authority, Mr. Bellamy Gardner. The illustrations are good and instructive. At the end of each chapter is a full bibliography, and it is clear that the writing of the book has involved a great deal of assiduous research. The work is slightly marred by some typographical errors, and in a few places the construction of sentences is defective or highly involved. This remark applies especially to paragraphs on pages 18, 20, 23, and 69. The defects are the more noticeable because in the main the writing is singularly good and clear, and they will no doubt be corrected in the next edition, which we hope Mr. Yearsley will soon be called upon to bring out.

FURNEAUX ON PRACTICAL HYGIENE. (a)

The Board of Education have rightly insisted that candidates for its examination in hygiene should undergo a practical training, and not merely be crammed with ill-understood book information, or have listened to a given number of lectures. This is well, and marks an advance in methods which cannot but prove beneficial to students. The study of domestic science, as the author of this excellent little work clearly shows, is too frequently pursued in such a manner that but vague ideas are formed of the physical and chemical laws on which science is based, and consequently many of the expressions constantly in use convey but a feeble impression of their true meaning and significance.

The object of this book is to provide the student with a practical guide to elementary physics and chemistry, as far as is necessary to form a sound basis for the study of domestic science. The student is led through a series of simple exercises and experiments, each of which may be performed with apparatus of the simplest kind.

The descriptions are clear, concise, and thoroughly practical. The illustrations are peculiarly suitable. Both in design and in execution the work is praiseworthy. We venture to think it will prove of service, not only for the purpose for which it was originally designed, but as a convenient volume to which medical men might refer with advantage when preparing lectures for nurses, or discourses on health matters for the people.

CHILDREN'S DISEASES. (b)

THE newly-formed Society for the Study of Disease in Children may be congratulated on the success which a membership of 237 in the first year of its existence shows it to have attained, and also on the publication of the volume now before us, which contains such a record of useful work as more than to justify the existence of this society. Consisting as it does of clinical reports of cases shown at the nine meetings of the Society, it is not a volume which lends itself readily to review or summary, and it is only possible to mention some of the more important papers. The subject of renal disease in children is discussed by Dr. Sequeira in a report of a case of Cirrhotic Kidney, by Dr. Leonard Guthrie in a paper on Chronic Interstitial Nephritis, and by Dr. Ashby, who records a case of Glomerulo-Nephritis in a newly born infant. Perhaps the most important contribution in the volume is that by Drs. Carpenter and Stevenson on Tubercle of the Choroid. They find it in 50 per cent. of cases of Acute Miliary Tuberculosis and Tuberculous Meningitis, and nearly 10 per cent. of cases of Chronic Tuberculosis. From their observations it seems undoubted that the gravity of the prognosis when tubercles are found has been overestimated, and that in rare instances recovery may ensue, the choroidal tubercle becoming quiescent as the general condition improves. We have not space to do more than allude to articles by Dr. Ashby on Fœtal Rickets, by Dr. Sansom on Osteo-Arthritis, by Dr. Carpenter on Multiple Fibrous Nodules in an infant

(a) "The Treatment of Neurasthenia." By Dr. A. Proust, Professor of the Faculty of Medicine of Paris, &c., and Dr. Gilbert Ballet, Professor of the Faculty, Physician to St. Antoine Hospital, Paris. Translated by Peter Campbell Smith, L.R.C.P., L.R.C.S. Ed. London: Henry Kimpton. 1902.

(b) "Adenoids." By Macleod Yearsley, F.R.C.S. London: The Medical Times Office. 1901. Pp. 110, 25 illustrations. Price 5s.

(a) "Elementary Practical Hygiene" (Section I.). By William S. Furneaux. Pp. 239, and 146 figures. London: Longmans, Green, and Co. 1901.

(b) "Reports of the Society for the Study of Disease in Children." Vol. I., Session 1900-1. London: J. and A. Churchill. Price 12s. 6d.

apparently free from rheumatism, and upon the urine of a newly born child, by Dr. McCaw on Tetanus Neonatorum, and by Dr. McAlister on Cirrhosis of the Liver in Children. The volume is of convenient size, the type is clear, there is a good index, and the illustrations are nearly all excellent.

NEW BOOKS AND NEW EDITIONS.

The following books have been received since the publication of our last monthly list:—

ADLARD AND SON (London).

King's College Hospital Reports. Vol. VII. Edited by Norman Dalton, M.D., Albert Carless, F.R.C.S., John Phillips, M.D., and W. D. Halliburton, M.D., F.R.S. Pp. 457.

BAILLIERE, TINDALL, AND COX (London).

The Practitioners' Handbook of Diseases of the Ear and Nasopharynx. By H. Macnaughton-Jones, M.D., F.R.C.S., W. B. A. Stewart, F.R.C.S., Wm. Milligan, M.D., C. M. Herbert Tilley, M.D., F.R.C.S., Ambrose Birmingham, M.D., F.R.C.S., and Robert D. Joyce, F.R.C.S., with 182 illustrations and 7 plates. Pp. 384. Price 10s. 6d. net.

Clinical Lectures on Stricture of the Urethra and Enlargement of Prostate. By P. J. Freyer, M.D., M.Ch. Second Edition. Pp. 138, illustrated. Price 5s.

The Dynamic Aspects of Nutrition and Heredity. By Frank Horridge. Pp. 192. Price 5s.

Clinical Lectures on Hydatid Disease of the Lungs. By Alfred A. London, M.D. Lond. Pp. 132, with 3 plates and other illustrations. Price 5s.

Notes on Medicine for Medical and Dental Students. By W. D. Woodburn, L.D.S. Pp. 98. Price 3s. 6d.

CASSELL & Co. (London).

Clinical Methods. By Robt. Hutchison, M.D., M.R.C.S., and Harry Rainey, M.A., F.R.C.P. Ed. New Edition, revised. Price 10s. 6d.

J. AND A. CHURCHILL (London).

The Year-book of Pharmacy, with Transactions of the British Pharmaceutical Conference, 1901.

The Schott Methods of Treatment of Chronic Diseases of the Heart. By W. Besley Thorne, M.D. Fourth Edition. Pp. 138. Price 6s.

The Diseases of Children. By James F. Goodhart, M.D., LL.D. Aberd., F.R.C.P. Seventh Edition, with the assistance of Geo. F. Still, M.D., F.R.C.P. Pp. 813. Price 12s. 6d. net.

Clinical Lectures on Surgical Subjects, delivered by Christopher Heath, F.R.C.S. Second Series.

FANNIN AND Co. (Dublin).

Transactions of the Royal Academy of Medicine in Ireland. Vol. XIX. Edited by John B. Story, M.B., F.R.C.S., General Secretary. Price not stated.

WILLIAM GREEN AND SONS (Edinburgh).

Manual of Ante-natal Pathology and Hygiene. The Fetus. By J. W. Ballantyne, M.D., F.R.C.P.E. Pp. 527. With 15 coloured plates and 55 figures. Price 20s.

GRANT RICHARDS (London).

Heresies or Agnostic Theism, Ethics, Sociology, and Metaphysics. By R. Croft. Pp. 597. Price 10s.

HEALTH RESORTS DEVELOPMENT ASSOCIATION.

1. Llandrindod Wells. Edited by George W. Way.

2. Deal. Edited by George W. Way.

KEGAN PAUL, TRENCH, TRUBNER, AND Co., LTD. (London).

Bradshaw's Dictionary of Mineral Waters, Climatic Health Resorts, &c. 1902. Price 2s. 6d.

E. AND S. LIVINGSTONE (Edinburgh).

Elementary Text-book of Zoology. By Arthur T. Masterman, M.A. Cantab., F.R.C.S. Ed. Second Edition. Pp. 628. Price 12s.

LONGMANS, GREEN, AND Co. (London).

A Manual of Surgical Treatment. By W. Watson Cheyne, F.R.C.S., F.R.S., and F. F. Burghard, M.D., F.R.C.S. Part VI., with 124 illustrations. Pp. 479. Price 18s.

The Earth in Relation to the Preservation and Destruction of Contagion. By G. Vivian Poore, M.D., F.R.C.P. Lond. Pp. 257. Essentials of Histology. By E. A. Schafer, LL.D., F.R.S. Sixth Edition. Pp. 416.

Drink, Temperance, and Legislation. By Arthur Shadwell, M.A., M.D., Oxon. Pp. 304.

The Thompson Yates Laboratories Report. Edited by Hubert Boyce and C. S. Sherrington. Vol. IV. Part II. Price 20s.

THE NEW SYDENHAM SOCIETY (Agent: H. K. LEWIS).

The Pathology of the Blood. By Dr. Rud. R. von Limbeck. Translated from the second German edition by Arthur Latham, M.A., M.B.C.P. Lond., and John Nachbar, M.D. Pp. ix, and 338.

Selected Essays and Monographs. Pp. 325.

OLIVER AND BOYD (Edinburgh).

Manual of Bacteriological Technique and Special Bacteriology. Second Edition. By Thos. Bowhill, F.R.C.V.S., F.R.P.S. Pp. 324, with 136 illustrations.

G. P. PUTNAM'S SONS (New York).

The Mental State of Hystericals. By Pierre Janet, Litt.D., M.D. Translated by Caroline E. Corsey. Pp. 535.

REBMAN, LTD. (London).

Clinical Hematology. By John Da Costa, M.D. With eight coloured plates. Pp. 474. Price 22s. 6d.

A System of Physiologic-Therapeutics. Edited by Solomon S. Cohen, M.D. Vol. II. Dietotherapy and Food in Health. Pp. 372. Price 12s. 6d.

Tuberculosis as a Disease of the Masses. By S. A. Knoff, M.D., New York. Pp. 76. Price 1s.

Christian Science, Medicine, and Occultism. By Dr. Moll, of Berlin. Translated by F. J. Rebman. Pp. 47. Price 1s.

THE UNIVERSITY PRESS (Chicago).

Neurological Technique. By Irvine Hardesty, Ph.D. Pp. 183. Price 8s.

THE UNIVERSITY PRESS (Dublin).

The Royal University of Ireland. Examination Papers, 1901. Pp. 660.

VERLAG DER MEDIZINISCHEN WOCHEN (Berlin).

Praktische Winke für die Diabetes-Küche. Von Dr. W. H. Gilbert, Baden-Baden. Pp. 72.

JOHN WRIGHT AND Co. (Bristol).

Protoplasm, its Origin, Varieties, and Functions. By J. W. Hayward, M.D. Pp. 51. Price 1s. 6d.

New Medical Appliances.

COMPRESSED MOSS.

WE have received from Mr. Martindale, of New Cavendish Street, W., various samples of compressed moss for surgical dressings, &c. The absorbent properties of dry moss are well known; in fact it will absorb about twenty times its weight of moisture. In addition it possesses marked antiseptic and deodorant qualities which make it very suitable for surgical purposes. The compressed sheets are easily teased out, and then form soft absorbent compresses which can be applied to suppurating surfaces between two layers of gauze. There are several kinds, varying in thickness and fineness of texture. The substance is also employed in the form of moss felt and moss soles for the feet, and is made up into hygienic towels. As the moss does not become matted its softness remains, ensuring a degree of comfort unattainable with cotton wool for instance. The moss may also be used as a padding for splints in cases of compound fractures complicated with flesh wounds. The cost is a negligible quantity, and we see no reason why moss should not come into general use for these purposes.

A POISON-BOTTLE COLLAR.

DR. HADYN BROWN, of Surbiton Hill, has submitted to us an ingenious invention of his own which has for object to distinguish bottles containing poisonous substances from others. It consists of a tin ruff or collar with a serrated circumference, and stamped with the word "poison" in large raised letters. This can be slipped over the neck of any bottle, and when in place it is impossible to move the bottle without becoming aware of its presence partly by the rattle it makes and partly by sight; or, if handled in the dark, the prickly shape of the metal would at once attract attention. The cost of the contrivance is the merest trifle, and in view of the recent fatal accidents on the part of chemists and dispensers it is to be hoped that the contrivance will command a ready sale. When placed on liniment bottles the collar can be tilted aside so as to allow of the bottle being wrapped in paper. It certainly affords a simpler and on the whole more effectual safeguard against accidental poisoning than any we have yet seen.

THE widow and orphans of Dr. Robt. Barry, who died from the effects of a carriage accident at Limerick, were yesterday awarded £300 damages in consequence of the negligence of the defendants' servant.

Medical News.

A Sanatorium Burned Down.

The sanatorium of the St. Luke's Society in Chicago was destroyed by fire on Monday, ten persons being killed and thirty injured.

Association for the Prevention of Tuberculosis.

The annual meeting of the Dublin branch was held on Monday, June 9th, the President of the Royal College of Physicians in the chair. The annual report regretted that the efforts of the Public Health Committee of the Dublin Corporation to promote the voluntary notification of pulmonary tuberculosis had so far met with little success. During a period of six months only sixty-five cases of this disease were notified, chiefly by dispensary physicians. As an objection to the addition of pulmonary tuberculosis to the list of diseases notifiable under the Infectious Diseases (Notification) Act, 1889, it has been urged with truth that such a procedure would prevent many persons in the early stages of the disease from earning their living or mixing with their fellow-men, as the penalties incurred by persons who, while suffering from any dangerous infectious disorder, wilfully expose themselves in public would then apply to them. The time seems now to have come when an amending Bill might be introduced in Parliament to bring pulmonary tuberculosis within the scope of the compulsory Act, except in regard to the provisions above objected to. The adoption of the report was proposed by the President of the Royal College of Surgeons and carried. Sir John W. Moore proposed:—"That this meeting urges on our sanitary authorities to adopt voluntary notification of consumption for the thorough disinfection of all dwellings occupied by a consumptive, provide sanatoria for the treatment of mild cases, and provide for the isolation of advanced cases of consumption." He said that the statistics for 1890 showed that pulmonary consumption accounted for 42,987 deaths in England and Wales. In Ireland in the same year 10,676 deaths were referred to pulmonary consumption, while the average number of deaths for the previous twenty-nine years was 10,143. There was no diminution in Ireland. Though the people had diminished, the number of deaths had been almost steadily maintained. That mortality represented in Ireland 2,260 per million of the population, as against 1,332 in England and Wales. The Local Government Board had recently given to the Dublin Sanitary Association a most remarkable reading of the provisions of the Public Health Act of 1878. There was a section of that Act which covered dangerous infectious diseases, and the Sanitary Association asked the Local Government Board whether that section could be made to apply to pulmonary consumption, and the answer was no, that that section only applied to the diseases scheduled in the Notification Act. Now, unfortunately for the Local Government Board, the next section to the one which was referred to in the schedule gave the sanitary authorities power to add to that schedule any disease which, in their opinion, was a dangerous infectious disease. The resolution was adopted, and then, after the transaction of the remaining business, the meeting terminated.

A Put-up Job.

DR. A. H. GIBBON, medical officer of health for Bury, brought an action which was tried at the Suffolk Assizes against a member of the Bury Town Council for slander. The defendant was alleged to have stated in public that the small-pox scare was a "got-up job" between Dr. Gibbon and the public vaccinator. The jury returned a verdict in favour of the plaintiff with one farthing damages.

Ulster Medical Society.

THE ANNUAL meeting of this Society was held on Thursday evening, the 12th, Professor Whitla, the President, in the chair. The annual reports and state-

ment of accounts showed an increase in the membership, and a balance of about £100 in the treasurer's hands. The new constitution and rules for the Society, necessitated by Professor Whitla's gift of a medical institute, were discussed at length, and passed. They provide, *inter alia*, that in future there shall be two classes of members—fellows and ordinary members—the former paying two guineas per annum if resident in Belfast, or one guinea if in the country, and ordinary members paying one guinea. Present members of the Society may remain ordinary members for life if they so wish (though the great majority have already intimated their intention of becoming fellows), but those elected in future will cease to be members ten years after the date of registration, and unless they become fellows their connection with the Society must cease. The idea is, in fact, that the great majority must pay two guineas, but that a special concession is made to country members, and to town members for ten years after their registration as medical practitioners, when presumably they are fighting their way in our crowded ranks. The new rules also provide that the president shall hold office for two years, that meetings be held on the first and third Thursday of each month from November to May, alternately at 4 and 8.30 p.m. and that the Council shall consist of twenty-one members, of whom seven are trustees, and as such *ex officio* members. The first seven trustees are to be nominated by Professor Whitla, and their successors will be elected by the Society. The rules having been passed, Professor Whitla read the trust deed of the new institute, and announced the names of those whom he intends to nominate as trustees. They are as follows:—Dr. John Campbell, F.R.C.S.E., Dr. Dempsey, Professor Lindsay, Dr. McCaw, Dr. Mitchell, F.R.C.S.I., Dr. Joseph Nelson, and Dr. Cecil Shaw. The office-bearers for next session were then elected as follows:—President: Dr. John Campbell, F.R.C.S.E. Vice-Presidents: Dr. Agnew (Lurgan), Dr. Austen. Hon. Treasurer: Dr. W. B. McQuitty. Hon. Secretary: Dr. Thos. Houston. Hon. Librarian: Dr. R. R. Leatham. Hon. Pathological Secretary: Professor Lorrain Smith. Council: Professor Byers, Drs. Colville, Donnan (Holywood), J. B. Moore, Morrow, and Robb.

Livingstone College.

ON June 14th a conversazione was held at Livingstone College, and interesting demonstrations given on various material connected with hygiene in the tropics by Dr. Charles F. Harford. Livingstone College has been established for the purpose of teaching intending missionaries how to care for their own health and that of their fellow-workers, and to indicate the best methods of dealing with the more simple diseases of the natives of the country in which they may be called to work. It is not intended to train men as "medical missionaries," and those entering for the course of training are required to sign a declaration that they will not take to themselves this title, or otherwise assume the position of a qualified doctor. There is certainly as much need to teach would-be missionaries hygiene as to lecture them on theology, and Livingstone College will be doing a good work if it succeeds in impressing the importance of care for the body by those who undertake the "cure of the soul."

The Prince of Wales and St. John Ambulance Brigade.

THE Prince of Wales on June 11th, in his capacity of Grand Prior of the Order of the Hospital of St. John of Jerusalem in England, unveiled at the church of St. John, Clerkenwell, the memorial which has been erected to the memory of the members of the St. John's Ambulance Brigade who have died on service in South Africa. The total number of men who have served is 2,046, and in the performance of their duty sixty-six are known to have sacrificed their lives. After the unveiling a bugler sounded the "Last Post." Now that peace is once again our true cause of rejoicing it is well that we should not be slow to honour the memory of those who have laid down their lives while ministering to the sufferers in the days of war.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE NEGRO AND THE DOLLAR.

To the Editor of THE MEDICAL PRESS and CIRCULAR.

SIR,—The story in your last issue (page 644), under the above heading, recalls to memory an account in the *Lancet*, in 1892, a cutting of which I have by me, headed "A Curious Incident," in which a certain Lord A.—swallowed a half-crown, "and after a protracted illness got rid of one shilling, two sixpences, a three-penny-bit, and three bright pennies," the exact change for half-a-crown! He was under the care of Dr. Mint. Probably the whole thing is "mint" for a joke? It is, however, satisfactory to know the patient was too honest to attempt to pass any base coin! It is sad to learn that he died, as, had he lived, he could have been utilised as a chance bureau. Poor fellow! He "paid the debt of nature" but not with the half-crown. His motto must have been, "You'll find no change in me."

I am, Sir, yours truly, A. D.

DR. JOHN CAMPBELL.—We hope to have space for your paper on "The Treatment of Dysmenorrhœa" in our next.

DR. E. L.—Our attention had been called to the local reference by another correspondent, but the name was probably drawn in without the sanction of the gentleman concerned. At least, this is the view we have formed on reading it.

ELBEK.—Undoubtedly crowded out at press.

THE PHYSIOLOGY OF SLEEP.—BEDROOM VENTILATION.

To the Editor of THE MEDICAL PRESS and CIRCULAR.

SIR,—Referring to the interesting article in your issue June 4th, on the "Physiology of Sleep," would you allow me to state that an effective and an expeditious ventilator, free from draught, may be formed by fixing a sheet of glass or a thin board (glass preferred, as it does not obstruct the light), say six inches wide, to the inside of the sill of a window, which should then be opened two or three inches. This makes a splendid "inlet" ventilator, while the chimney, of course, acts as an outlet ventilator. It also allows of blind being drawn to within six inches of sill, to darken room at night, and it saves the metal mountings of the blind from rain or damp.

I am, Sir, yours truly,
J. J. MEAGHER,
Architect.

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, JUNE 18TH.

ROYAL METEOROLOGICAL SOCIETY (Society's Rooms, 70, Victoria Street, S.W.).—4.30 p.m. Papers: Mr. F. C. Bayard: English Climatology, 1891-1900. Mr. W. L. Dallas: Earth Temperatures Recorded in Upper India.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. E. W. Moughton: Clinique. (Surgical.)

THURSDAY JUNE 19TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.)

FRIDAY, JUNE 20TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. W. Dodd: Clinique. (Eye.)

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (Pendlebury Children's Hospital, Manchester).—4 p.m. Papers: Dr. A. E. Sansom: Some Remarks on Heart Disease in Children. Mr. W. P. Montgomery: On Tendon Grafting, with Cases.—Dr. H. Ashby and Dr. G. Carpenter: On Splenic Enlargements, with some Observations on the Blood.—Dr. E. Cautley: Atresia of the Conus Pulmonalis, with Patent Septum Ventriculorum. Mr. C. M. Gwynne (Sheffield): The Surgical Treatment of a Case of Infantile Paralysis of the Lower Extremity.—Mr. S. Stephenson: Fleeting Amaurosis in Children presenting Symptoms of Meningitis.

MONDAY, JUNE 23RD.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover Square, W.).—Communications by Mr. Arthur Underwood. Paper by Dr. Sim Wallace on "Some Effects of Refinement of Food." The President will deliver his Valedictory Address.

Appointments.

BARTON, GEO. ALEX. HEATON, M.D.Brux., M.R.C.S., L.R.C.P., L.S.A.Eng., Second Anesthetist to the North-West London Hospital.

COCKILL, W. B., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory Act for the Kendal District of Westmoreland.

CRIMP, C. L., B.A., B.C.Cantab., Assistant Medical Officer to Bethnal House Asylum, E.

CRUICKSHANK, E. W., M.B., M.S.Aberd., Certifying Surgeon under the Factory Act for the Eynsham District of the County of Oxford.

FORDE, G. B., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory Act for the Rochford District of Essex.

GLEGG, WILFRID, M.D., C.M., M.R.C.P.Ed., Assistant Surgeon to the Birmingham and Midland Ear and Throat Hospital.

GRIFFIN, INNES, M.R.C.S., L.S.A., Certifying Surgeon under the Factory Act for the Banbury District of Oxford.

LAMBERT, E. A., M.D.Ed., Certifying Surgeon under the Factory Act for the East Isley District of Berks.

MACKENNIK, ERNEST, M.D.Glasg., Certifying Surgeon under the Factory Act for the Cheadle District of Staffs.

MOORHEAD, RUPERT E., L.R.C.P., L.R.C.S.Ed., L.F.P.S.Glasg., Medical Officer and Public Vaccinator for the Fourth District of Bath.

PICKERING, G. W., L.R.C.P., L.R.C.S.Ed., L.F.P.S.Glasg., Certifying Surgeon under the Factory Act for the Haltwhistle District of Northumberland.

SYKES, WALTER, L.R.C.P.Ed., M.R.C.S.Eng., Senior House Surgeon to the Birmingham and Midland Eye Hospital.

TROTTER, ALEXANDER, M.B., B.Ch.Ed., Resident Surgical Officer to the Birmingham and Midland Eye Hospital.

WINTERBOTHAM, EATYER, M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory Act for the Brixworth District of the County of Northampton.

Vacancies.

Birkenhead Union.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Clerk's Office, 45, Hamilton Square, Birkenhead.

Bristol City Lunatic Asylum.—Medical Assistant. Salary £140 per annum, with furnished apartments, board, and washing. Applications to Edmund J. Taylor, Clerk to the Visiting Committee, The Council House, Bristol.

County of London.—Medical Superintendent of the Epileptic Colony Asylum, Horton, Surrey. Salary £300, rising to £600, with house, rates, taxes, and water free. Applications to E. W. Partridge, Esq., London Asylums Committee Office, 8, Waterloo Place, S.W. (See advt.)

Fisherton Asylum.—Assistant Medical Officer. Salary £150 per annum, with board lodging, and washing. Apply to Dr. Finch, Salisbury.

London Hospital, Whitechapel, E.—Surgical Registrarship. Salary £100 per annum. Applications to G. Q. Roberts, Secretary and House Governor.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160 per annum. Furnished apartments, attendance, light, and fuel. Applications to Secretary, M. I. Preston, Journal Chambers, Nottingham.

Parish of St. Marylebone.—Medical Officer, Southall Schools. Salary £100 per annum. Application to the Clerk to the Board, Guardians' Offices, Northumberland Street.

Queen's College, Ireland.—Dunville Professorship of Physiology in the Queen's College, Belfast. Applications to the Under Secretary, Dublin Castle. (See advt.)

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £110 per annum, with board and lodgings. Applications to Chas. W. Dickinson, Capt. R.N., Secretary, Royal Albert Hospital, Devonport.

The Hartlepool Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and lodging in the institution. Applications to Robert M. Edger, Assistant Secretary, 9, Albion Terrace, Hartlepool.

Valkenburg Asylum, Mowbray, near Cape Town.—Assistant Medical Officer. Salary £300 per annum, with board, lodging, and washing. Applications immediately to the Agent-General for the Cape of Good Hope, 100, Victoria Street, London, S.W.

Marriages.

MORTON—BOULTON.—On June 7th, at Christ Church, Harrogate. John Leyden Morton, M.D., son of Thomas Morton, M.D., of Kilburn, to Sarah Gertrude Boulton, youngest daughter of the late S. Boulton, of Liverpool, and adopted daughter of Mrs S. Cash, of 3, Granby Road, Harrogate.

TEALE—WOOD.—On June 7th, at St. Hilda's Church, Darlington. Alan Isherwood, second son of the late John W. Teale, M.D., F.R.C.S., J.P. of Scarborough, to Lydia, youngest daughter of William Wood, Speedwell, Darlington.

WALES—DOWLING.—On June 11th, at All Saints', Marple, Edward Garneys Wales, M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P., son of Thomas Garneys Wales, Downham Market, Norfolk, to Annie, elder daughter of E. J. Dowling, Beech House, Torkington, near Stockport.

Deaths.

BARNES.—On June 10th, at Dartmouth Park Road, Highgate Clifford Henry Barnes, M.B.Camb., in his 30th year.

DICKINSON.—On June 11th, at Allassio, Italy, Edward Dickinson, M.R.C.S.Eng., formerly of Rugby, in his 89th year.

Original Communications.

ON THE CLINICAL FEATURES AND POST- MORTEM APPEARANCES OF A CASE OF DECIDUOMA MALIGNUM. (a)

By J. HALLIDAY CROOM, M.D., F.R.S.E.,
F.R.C.S. Edin.

President of the Royal College of Surgeons, Edinburgh;
President of the British Gynaecological Society.

I VENTURE to bring this paper before you, not because I believe that I can add anything to the existing knowledge of the subject, but rather because I trust that I shall be able to illustrate some points in its clinical features and pathological aspect by a case that has come under my observation.

The subject of deciduoma malignum has already been discussed in the Society at length in consequence of a most valuable paper written by my friend and colleague, Dr. Haultain; and the views he propounded then seem gradually to have gained acceptance. Since the subject was first broached by Saenger, the literature has been gradually accumulating to a very large extent, yet in its secondary manifestations, and in the infrequency of its occurrence, there is still a wide field for further study. As to its exact nature—though the subject has been copiously discussed—it cannot be said that its pathology has yet been absolutely decided. The contention of one party, that it is a sarcoma, as held by teachers in the metropolis here as well as in this Society, has been, I think, to a very great extent, discarded, and I believe that by far the greater consensus of opinion is in favour of its being epitheliomatous, the result of a pregnancy, and originating from the coverings of the villi.

The cases which have been recorded present great similarity in their clinical features. There is generally, in a patient of the age of thirty or thereby, the history of profuse bleedings following abortion or ordinary labour, and in 60 per cent. of cases following myxoma of the chorion, the hæmorrhage being succeeded by foul-smelling discharges and the evacuation of masses of blood clot and shreddy tissue from the uterus. Metastatic deposits in the vagina, in the lungs, in the brain, &c., commonly lead to death in cases where prompt extirpation of the uterus is not had recourse to. There is very marked cachexia, and so rapid a progress of symptoms that the whole history of the case, from the first observation of any abnormal condition to the death of the patient from lung or other secondary complications, may not occupy a longer period than a few months or even weeks. There is, as a rule, no great difficulty in recognising the condition, and there is only one possible method of treatment, namely, early extirpation of the uterus. But where the difficulty arises is in relegating the disease to its true place in pathology, and here there are nearly as many theories advanced as there have been observers.

Saenger believed the growth to be from decidua cells, hence his name for it—Deciduoma Malignum.

(a) Read before the British Gynaecological Society, April, 1902.

Gottschalk advanced the hypothesis that malignant degeneration of the stroma of the chorionic villi produced the condition, which he named "Sarcoma chorio-cellulare."

Fraenkel considered the sole origin of the tumour to be from the epithelium covering the villi, and that it was therefore a carcinoma.

Gebhard believes the growth to be a mixed carcinoma of maternal and foetal structures.

Marchand, whose work on this subject is extremely valuable, advanced in 1895 a view which is still, I think, generally recognised to be the true one regarding the origin of the condition. Briefly, he holds that the tumour arises from both the kinds of tissue composing the epithelial layers of the villi, namely syncytium and Langhans' cells, which undergo a malignant degeneration and proliferation, resulting, in the case of the syncytium, in the formation of large cells with large nuclei, polynucleated protoplasmic masses or giant cells, and multinucleated trabecular protoplasmic structures surrounded by blood spaces; while the Langhans' cells become polyhedral clear cells, smaller than the giant cells. He also believes that the metastases form by way of the blood vessels, and that decidua cells take no part in the growth.

The three observers last named thus appear to agree in regarding the natural character of the growth as epithelial, and differ merely upon the yet debatable ground of the origin of the syncytium from foetal or maternal structure.

Marchand's teaching is entirely supported by the work of Haultain, whose views, very carefully and fully laid before this Society in 1899, are essentially the same as those held by the very latest writers on the subject. The difference of opinion between Marchand and the earlier observers probably arose from the fact that Marchand was the first observer to find villi in a case of this kind. The presence of villi was afterwards demonstrated by Haultain in a case which conclusively proved the origin of the proliferating cells to be from their epithelial covering. In the current number of the *American Journal of Obstetrics* there is an elaborate and careful discussion of the whole subject by Dr. Pierce, of Chicago, but his conclusions only confirm what we learned of the subject in 1899. If its origin from the chorionic villi be accepted, deciduoma forms a unique growth of a parasitic nature and, necessarily, can only arise after pregnancy. So far, this cannot be contradicted, no case having yet been described without a previous pregnancy, which is not open to objection.

An interesting feature connected with the origin of the growth is the great frequency with which it follows myxoma of the chorion. This, however, is only to be expected when we remember that this so-called chorionic degeneration is in reality due to an intense proliferation of villous epithelium. The mere fact of deciduoma being so often a sequela of vesicular mole is therefore one of the strongest proofs of its epithelial origin; it is merely a maintenance of the usual epithelial proliferation found in that condition.

In the majority of cases the area of active growth is situated superficially in the uterine cavity and then forms a tumour which bulges into that cavity. On

section, the growth presents the appearance of placental tissue, being mainly composed of blood clot, but on microscopic examination it shows the characteristic multinucleated granular masses and large nucleated cells derived from the syncytium and Langhans' layer of the villi respectively. If the area of origin be found, it will probably show chorionic villi whose epithelial coverings are in an intense state of proliferative activity.

The case to which I specially refer was as follows. The patient, *et.* 44, was admitted to my ward in the Royal Infirmary, Edinburgh, on June 14th, 1898. She had had five children, the last in August, 1892. She had also had two miscarriages, one between the birth of the first and second child, and the last six years before her admission. Her menstruation had been quite regular every twenty-eight days, lasting six or seven. She had not menstruated since February, 1898, until the end of May, and was under the impression that her change of life had arrived, especially as her recent periods had been associated with more severe hæmorrhage than usual. There had been some inter-menstrual leucorrhœa of an offensive character. She had observed a swelling of her lower abdomen, but she had only noticed it a few weeks before she came to the Infirmary. Except leucorrhœa, there was no discharge of any kind. She had complained from time to time, recently, of attacks of pain.

The woman was extremely emaciated, and on examination I found, stretching up to midway between the pubis and umbilicus, a tumour, hard, firm and consistent, which, from the history and nature of the case, I took to be a rapidly growing sarcoma. I observed on the left labium a small tumour, about the size of a walnut, situated in the region of the Bartholin's gland on the left side. This I took to be an ordinary retention cyst in the Bartholinian duct, and, as it gave her considerable pain, opened it before doing anything to the larger tumour, and was surprised to find that it was not a Bartholinian cyst at all, but a solid mass, which could only be enucleated with difficulty, and was of a structure unknown to me. This very peculiar tissue was subjected to microscopic examination, and, as it presented appearances similar to those of deciduoma malignum, I was led to alter my opinion with regard to the uterine tumour, and determined to operate without delay. Unfortunately, the patient sank very rapidly, lung complications having set in, and died before it was possible to do so.

In its clinical history this case, you will perceive, is somewhat different from those already described. First of all, the patient was beyond the average age of women the subjects of deciduoma, for though these tumours have been met with between the limits of seventeen and fifty-five, the mean age of their occurrence is thirty-three. This woman was forty-four.

As to the question of the age incidence: deciduoma may occur at any stage of a woman's reproductive life; in the cases collated by McKenna, the youngest was seventeen and the oldest fifty-four. Its occurrence is most frequent in the second decennium of the reproductive cycle. The figures fall off considerably both at the beginning and at the end of reproductive life. It is most instructive therefore to observe that these tumours develop just at that period of a woman's life when conception is most frequent, and this is just the very opposite of what we find in sarcoma, for sarcoma is comparatively rare under thirty-five, and most common between forty and sixty. As has been very well remarked by McKenna, too much attention has perhaps been paid to the microscopic character of the tumour cells and too little to the age incidence of the tumour.

Again, it must be noted that in this particular instance the affection did not occur, as it usually does immediately after pregnancy, the last recognised pregnancy having ended in abortion six years previously. This is a rather curious and interesting fact, for, in the recorded cases, it has been shown conclusively that this disease—deciduoma malignum, or by whatever name it is known—occurs in distinct relation to pregnancy, and very often in connection with a myxoma of the chorion. So far as I am aware, no case has been recorded in

which the interval between pregnancy and the occurrence of the tumour has been so prolonged as in the one before us to-night. The rapid development of this tumour six years after a recognised pregnancy rendered the diagnosis of deciduoma malignum most unlikely, and it is difficult to see what relation there could be, if any, between the last recognised pregnancy and the development in the uterus of a tumour containing any of the elements of pregnancy whatever.

In the recorded cases, the average time of the occurrence of one of these tumours after labour has been 6.9 weeks, after abortion 11.4 weeks, and after myxoma, 10.0 weeks. In two instances only, so far as my knowledge goes, has there been anything approaching to so long an interval between pregnancy and the growth of the deciduoma malignum as in my case; these were the cases recorded by Hollmann and Löhlein, and both occurred after myxoma. In Hollmann's case there was four years' interval, and in Löhlein's case two years' interval. As McKenna has pointed out, if these were true cases of syncytium malignum, there must either have been some interrupted and unsuspected gestation between the time when the hydatid mole was expelled and that when the malignant neoplasm was observed; or remnants of myxoma must be capable of setting up malignant processes after a very long period of latency.

It must be noted that in my case the last recognised pregnancy, six years previously, was not a myxoma but an ordinary miscarriage. I admit that it is very difficult to see how the products of pregnancy could have remained so long latent and then have ultimately become active and developed this tumour. The only alternative left is to suppose that the sudden amenorrhœa in February was the result of conception, although one would have expected, as is usual in such cases, a hæmorrhage and an attempt at abortion, and no such symptom appeared. It is the fact that in the uterus no signs of pregnancy beyond the characteristic cells of the deciduoma malignum were found.

A further point which seems to me of extreme interest in this case is that, from the commencement of her amenorrhœa until the day she died, the patient had no hæmorrhage whatever. Now, so far as my reading goes, hæmorrhage has been the characteristic feature and the first symptom in almost every case of deciduoma malignum, beginning sometimes as soon as six weeks, and sometimes as late as two years, after delivery, the usual period being about six weeks. I have found no cases unassociated with hæmorrhage of this kind, except two.

Seanger's case was somewhat exceptional in this way. There was hæmorrhage so long as the abortion preceding the tumour was incomplete, but after the development of the tumour there never was any during its subsequent growth. In a case recorded by Bruce also, there was a similar absence of hæmorrhage. But as a rule almost without exception hæmorrhage is a characteristic feature, and the hæmorrhages are usually profuse, resembling those floodings which accompany abortion. They are also, as a rule, intermittent, but so abundant and frequent as to cause profound anæmia. In my own case, though there was never a trace of hæmorrhage of any kind, the patient was profoundly anæmic and cachectic.

The only discharge which was at all characteristic of deciduoma malignum was a bad smelling leucorrhœa, which was rather of a watery nature, suggesting rather an ordinary malignant disease of the uterus than deciduoma malignum. The passing of a sound showed the cavity of the uterus to be enlarged, and the sound felt as if it touched friable matter; on its removal, however, there was only the very slightest discharge of blood.

The short duration of the illness was quite in keeping with the character of the disease, because from the menstrual cessation in February, which was obviously the starting point of the illness, till her death in June, was only six months, and this is not an unusual duration for the disease.

Metastatic deposits in the labia have, of course, been already described in the recorded cases.

As to Diagnosis and Treatment.—Should the seat of origin be superficial, early symptoms of profuse hæmorrhage following the expulsion of the ovum will be present and thus closely simulate an ordinary imperfect abortion. From the early disintegration of the new growth a sanious discharge soon appears, followed by extreme cachexia, from the absorption of the toxins of decomposition, and, in default of timely operation, the patient rapidly succumbs from exhaustion, should she not already have become a victim to metastases in the lungs, brain or indeed any of the vital organs.

Unfortunately in a small number of cases the primary area of active growth is deep in the uterine wall where a malignant proliferating villus has travelled; indeed, sometimes the apparently initial growth may be found outside of the uterus, as in the vagina, ovary or other organ, owing to the migration of such a proliferating villus. In these cases the symptoms of uterine hæmorrhage are naturally absent, and the first indication of the disease may be due to metastatic foci in the lung or brain. In this latter type of case early diagnosis is impossible, and in many instances the truth is first known on the post-mortem table.

When, as in the majority of instances, uterine hæmorrhage is present, an early diagnosis can be made. The disease should be suspected if bleeding follow the expulsion of a vesicular mole, or return after curettage for

In illustration of the case the President showed the following specimens:—

1. Half the tumour, showing uterus, cyst and deciduoma.
2. Portion of the lung with secondary deposit.
3. Section of the tumour mounted on glass.
4. Section of the lung with large metastatic deposit.
5. A similar section with several smaller deposits, and the following microscopic slides:—(1) Characteristic cells in the area of active growth of the tumour; (2) centre of the tumour with mass of fibrin; (3) section from nodule on the uterus, with actively proliferating cells; (4) section from secondary deposit in the vagina.

Pelvis.—The pelvis was completely occupied by a large nodular mass which passed upwards into the abdominal cavity, to within two inches of umbilicus in middle line, and rather higher on the left side than on the right. The upper surface of this mass was thrown into large irregular nodules of uniform soft consistence, and apparently composed of necrotic tumour tissue and recent hæmorrhage. The posterior surface was comparatively smooth and non-adherent, and the rectum and ovaries were lying quite free behind it; laterally it reached out to both sides of pelvis, to which it was firmly adherent. Anteriorly the bladder was healthy, empty and adherent to the front of the mass. Extending above the bladder and between it and the uterus there was a large cyst

imperfect expulsion of the ovum. In these instances the uterine cavity should be thoroughly explored by the finger, and scrapings carefully examined microscopically.

When scrapings from a simple curettage are examined after the expulsion of a vesicular mole, the mere presence of multinucleated trabecular and solid protoplasm with chorionic villi cannot be considered a sufficient indication of the presence of the disease so as to warrant vaginal hysterectomy, as such appearances may be present from the retention of normal vesicular villi. Should the disease be malignant, the profuse character of the bleeding during the scraping of the uterus will form a far more valuable indication of the disease and may be corroborated by the microscopic appearances presented.

From the intense malignancy of the disease, early detection is most essential for a possibility of cure. It cannot be too strongly stated that repeated curettings without digital examination of the uterine cavity after imperfect abortion are to be avoided; at the same time, it is well to make it a rule to have all scrapings removed from a bleeding uterine cavity examined microscopically. The ease with which an expert opinion can now be got leaves no extenuating circumstances, should the disease be only diagnosed after months of hæmorrhage and when any hope of cure is out of the question.

filled with fluid. The tumour proper was infiltrating and expanding the fundus of the uterus.

The weight of this mass, 7 lbs. 7 ozs.; the maximum vertical length, 10½ ins.; maximum transverse breadth, 9 ins.

On removing the mass a small soft hæmorrhagic nodule, about 1 in. in diameter, was found on the left side of the upper vaginal wall.

[The report of the autopsy is given in detail, but the condition of the pelvis and the mass removed from it has, for convenience, been placed first.]

POST-MORTEM REPORT OF THE CASE BY DR. WELSH, Pathologist to the Royal Infirmary, Edinburgh.—The mass removed consisted of three portions formed by the bladder, the uterus with the tumour, and a cyst lying between the other two. 1. The bladder was completely adherent to, and was stretched up over the front of the cystic portion posterior to it. The length from urethra to the summit was 5 ins.

2. The cystic portion lay between the bladder which formed its anterior wall, and the tumour and uterus which formed its posterior wall. The cyst was completed above by a thick membranous structure 3½ ins. long, which bridged the space between the front and

upper part of the tumour and the upper end of the bladder.

The lower portion of the posterior wall of the cyst was formed by the anterior aspect of the cervix. Its lowest point lay exactly at the os externum, but separated from the anterior vaginal fornix by the bladder. The general site of the cyst was in the pouch of Retzius, or in the cellular tissue between bladder and cervix with peritoneum as its roof. Its walls were composed of a thin white tough membrane, which, where the bladder was contiguous to it, could be separated off the bladder wall, there being a little loose cellular tissue joining them together. At the upper portion the reddish purple structure of the tumour could be seen shining through the posterior wall. The lower part of this wall lying in front of the cervix (see *ante*) was free of tumour formation. There were one or two hæmorrhages into wall of cyst, which contained a bloody serous fluid under considerable tension, as it spurted out on incision. The length of the cyst from its upper end (the bridge of membrane $3\frac{1}{2}$ ins. long) to lower end (at level of external os) was 6 ins., its breadth (from tumour posteriorly to bladder in front) $3\frac{1}{2}$ ins.

3. Uterus and tumour; the cervix, unaffected by the deciduoma malignum, was 2 ins. in length. The body of the uterus measured 6 ins. from external os to the summit of the tumour, 4 ins. from back to front, and $4\frac{1}{2}$ ins. from side to side. The cavity of the body, $3\frac{1}{2}$ ins. in length, did not extend nearly to the summit; its antero-posterior breadth was $\frac{1}{2}$ in.; the posterior wall was $\frac{1}{2}$ in. thick and $3\frac{1}{2}$ ins. long. The new formation affected the anterior wall and fundus. Its shape was irregularly pyriform, its consistence firm, its length 6 ins., its breadth 4 ins.; it extended from the internal os to the summit of the whole uterine mass, and at the summit was adherent to the small intestine. Behind and to the left were the left ovary and tube, situated on a short pedicle of broad ligament $1\frac{1}{2}$ ins. from the middle line of the uterus posteriorly. The rest of the broad ligament was taken up by the tumour. On the extreme left the tumour was adherent to the descending colon. Anteriorly and to the left of the middle line the tumour was hummocky, and showed reddish purple hæmorrhagic areas. On section, it was firm, brittle, and showed in its centre a limited spherical portion $1\frac{1}{2}$ ins. in diameter, separated by a trench from the rest and apparently necrotic. Elsewhere the structure of the growth was red and spongy, hæmorrhagic looking.

The remainder of the report was as follows:—The body exhibited considerable emaciation; rigidity in lower limbs only. The abdominal tumour was especially prominent below umbilicus; walls loose and flaccid. P. M. discoloration.

Thorax.—The pericardium contained about 5 ozs. of serous fluid. No evidence of inflammation or new growth.

Pleura.—No apparent change in the pleura on either side. The left contained 35 ozs. of deeply, and the right about 2 ozs. of slightly, blood-stained fluid.

Heart.—Weight, $9\frac{1}{2}$ ozs. Chambers of right side occupied by ante-mortem clot.

Valves.—Arterial valves competent. Pulmonary, 0.1; aortic, 0.9; mitral, 1.25; 1.45. Slight chronic thickening along the attachment of the aortic segments; the other valves healthy; some patches of fatty degeneration, and slight atheroma of the aorta.

Left Ventricle.—Slightly dilated. Walls thin, muscle warped, flabby, and showed some anæmia and fatty changes. There were several minute foci of recent hæmorrhages grouped together just beneath endocardium on posterior surface of left ventricle near the auriculo-ventricular groove.

Other chambers practically normal.

Left Lung.—2 lb. 7 ozs. Very adherent along its posterior border. Greatly collapsed and compressed up against the root. The very irregular surface showed numerous nodules projecting and raised above general surface. The nodules varied in size up to 2 ins. in diameter, and were covered externally by a thin reticulated layer of fibrin, which had a bright red colour from dilated vessels and hæmorrhages just beneath it. On

section, many large nodules were found in lung substance, but the greatest mass was towards root of lower lobe, where several appeared to have run together. The upper lobe was greatly collapsed between the pressure of fluid in pleura and this mass of new growth at root of lower lobe. In section the nodules were of uniform and somewhat soft consistence, mottled pink colour with irregular patches of hæmorrhages and very largely necrotic.

Right Lung.—1 lb. 13 ozs. No adhesions. Also showed nodules of similar character, more numerous, but smaller, the largest only about 1 in. in diameter, much less elevated above surface and less depressed in centre, each covered with thin layer of fibrin which was only slightly reddened. On section many similar nodules throughout the lung tissue, which was anæmic and collapsed, but to less extent than the left lung.

Abdomen.—There was no ascites and no evidence of any acute peritonitis; only chronic adhesions in certain places. The anterior abdominal wall, from a point about 2 ins. below umbilicus downwards to pubis, was firmly adherent to a large nodular tumour mass growing up from the pelvis. To this mass also coils of ilium were firmly adherent in two places, one near the middle line, and the other towards the left margin of tumour. There were practically no adhesions between the tumour mass and any structures behind it, for the rectum passed down quite freely to the anus, and the ovary on each side was lying quite free. The pouch of Douglas was intact.

Liver.—4 lb. 11 ozs. The gall-bladder contained dark orange bile, no calculi; biliary passages quite healthy. On section the liver tissue showed some venous congestion, but no evidence of any malignant disease.

Spleen.—7 ozs. Very pale, soft and diffuent; no sign of new growth.

Kidneys.—Left 8 ozs., right 6 ozs. Both very anæmic, with fatty changes in the tubules of the cortex. The left in addition showed a few hæmorrhagic nodular and wedge-shaped areas in superficial cortex, very ill-defined and indefinite, probably early infarcti due to emboli from the new growth. Some of these found in right kidney.

Stomach, Intestines, and Rectum.—Showed no gross lesion apart from adhesions above noted, and also a small diverticulum about 2 ins. long in ileum about $4\frac{1}{2}$ ft. from ileo-cæcal valve.

Brain.—3 lbs. 1 oz. There was a small soft nodule about a $\frac{1}{2}$ in. in diameter, superficially and extending about $\frac{1}{8}$ in. into cerebral cortex occupying the middle mater on its inner surface showed an area of similar superficial extent covered by a thin layer of hæmorrhage and softened tissue. About an inch or more behind this there were several small hæmorrhagic points on inner surface of dura, but though the whole encephalon was carefully cut up no other gross lesion was detected.

THE TREATMENT OF DYSMENORRŒA. (a)

By JOHN CAMPBELL, M.A., M.D., F.R.C.S.Eng.,

Surgeon to the Samaritan Hospital for Women, and Assistant Surgeon to the Maternity Hospital, Belfast

I MAKE no apology for bringing under your notice the treatment of dysmenorrhœa. The affection is common enough, and its treatment troublesome enough, to make it interesting alike to the family doctor and to the specialist. I shall not now trouble you with any abstruse theoretical considerations, nor shall I ask you to follow me through any of the usual classifications. I shall simply approach the subject from the purely clinical standpoint, and shall consider the treatment of cases in accordance with the physical condition of the pelvic organs as discovered by examination.

Cases of dysmenorrhœa may be divided into two main classes, with sub-divisions, as follows:—

I.—Cases with no pelvic lesion:—

1. The anæmic.
2. The neurotic.

(a) Read before the Ulster Medical Society on May 8th, 1902.

II.—Cases with pelvic lesions:—

1. Uterus abnormal, appendages normal.
2. Uterus normal, appendages diseased.
3. Uterus displaced and appendages damaged.

I.—The cases with no pelvic lesion are those minor ones which require no local treatment and which, in unmarried women, do not even need a pelvic examination. They include the numerous young women whom we label anæmic or neurotic, those who, in plain English, neglect their bowels, take insufficient open-air exercise, and, either from necessity or fancy, use a deficient or an unwholesome dietary and clothing or footwear unsuitable to the vagaries of our climate. Among them we find people of all grades in the social scale. The servant girl, the ware-room girl, or the shop girl is often compelled by necessity to lead a life which lays the foundation of much suffering; while the more leisured maiden is almost equally strongly driven by the conventions of school or home life towards the same goal. The chief feature in these cases is the facility with which they respond to a course of general hygienic treatment, and they may for practical purposes be subdivided into the *anæmic* and the *neurotic*.

II.—The second class includes all those who resist the aforesaid general measures and need further investigation. Among them we have the anæmic and neurotic, but these terms can no longer be used to classify them into subdivisions, and so become of secondary importance, being subordinate to the physical condition in which the pelvic organs are found on examination. Hence in Class II. we have the following groups:—

1. The uterus abnormal, being in some cases a little too large, in others a little too small, and in many a little ante-flexed, but in all cases having its appendages free from recognisable deviation from the natural state.

2. The uterus approximately normal, but having its appendages somewhat diseased, whether in the form of thickened tubes, or adherent tubes, or enlarged, or inflamed, or adherent, or prolapsed ovaries.

3. The uterus retroverted or retroflexed or in that position which is described as retroversion and ante-flexion. Now this is a subdivision to which I would direct special attention, because the deviation of the uterus is such an obvious thing that it is liable to bulk too largely in the field of view and to lead us to become too mechanical in our treatment and to court woeful disappointment for both doctor and patient. That great past master in the art of gynecology, Lawson Tait, used to say that it did not matter what position a uterus lay in so long as it was healthy. There is a great deal of truth in this. To replace and keep in place the uterus of a woman who has been recently confined is, as a rule, the easiest thing in the world; but to replace and keep in place the uterus of a nullipara is, in the majority of cases, beyond the skill of mortal man. The reason is that in the former case the uterus has simply flopped back owing to its own weight, whereas in the latter it has fallen back during an attack of acute inflammatory congestion, or has been drawn backwards by the shrinking of adhesions or of inflamed ligaments, and the results of inflammation will remain in and about it throughout the patient's life. As a subject for treatment a uterus displaced to a slight or medium degree is far less favourable than one displaced to the utmost extent, because those adhesions or contracted ligaments which prevent it from going fully back will equally prevent you from getting it fully forward. Of these cases the worst of all is the retroverted and ante-flexed uterus. It has been the seat of ancient inflammation of a chronic kind, which has at the same time both pulled the uterus backwards and drawn it

bodily into the hollow of the sacrum, while leaving a marked ante-flexion as well. Under this subdivision we should also include the rarer lateral displacements to one or other side, as they owe their origin to similar inflammatory causes. In all these cases the local lesions found by examination are the main basis of our prognosis and treatment, but the period at which the menstrual pain commences may form a rough guide as to the condition in some cases. I refer to premenstrual pain, which commencing a few days or more before the flow appears is symptomatic of diseased appendages.

When a patient appears complaining of dysmenorrhœa the duty of the practitioner is clear. If she is married he examines. If she is unmarried he for a time treats her either for anæmia or neurosis, as may be indicated, and, if no improvement follows, he, at a future time, makes a careful examination, with or without an anæsthetic.

Taking now the question of treatment in detail, I need not weary you with much about the management of the anæmic and neurotic cases. Each one will have to be judged on its own merits, and the question of diet, exercise, clothing, and occupation dealt with to suit the patient. In the anæmic cases a course of iron and purgatives between the periods is essential. The milder preparations of iron do well if their use is prolonged. I prefer the ammoniated citrate of iron mixture for most cases, and the reduced iron in pill for those who have very good teeth. In cases where the tongue is foul and flabby a course of arsenic together with aloetic purgatives should precede the iron. For a week before and for the week of the period the iron should be stopped and the following given: R. potass. bromid., gr. x; tr. cimicifugæ, ℥xx; tr. bellad., ℥x; aq. chlorof., ʒss, three times a day. This will suit a large proportion of cases. Where it fails a quarter of a grain of extract of cannabis indica two or three times a day during the painful period will answer. Thus far treatment is easily managed, but the regulation of the bowels presents a serious difficulty in many cases. The kind of purgative does not much matter, and the one which the patient can be most easily got to take will be as a rule the best. The morning saline, the aloetic dinner pill, or the evening dose of cascara are all equally efficacious if taken regularly and in proper amount. Herein lies the chief difficulty. Many women and girls exhibit very little judgment in the regulation of the bowels by a laxative or purgative. They either take too much and then leave it off altogether for fear of it weakening them, or they take it irregularly, occasionally missing a dose or two, for social or other reasons, and so interrupting the regular daily evacuation of the bowel. The use of laxatives is particularly desirable before and during the period, and this is a time which tradition has labelled improper for the use of medicine, so that we often have to combat that idea.

In the cases where anæmia is not marked, and where neurosis seems to be a chief factor, the general management and the attention to the bowels will be the same as in the anæmic, but a greater variety of remedies will be required for the pain. The bromide and cimicifuga mixture does very well with some, but the cannabis indica does not suit as a rule on account of the excitement it is liable to produce. If the bromide and cimicifuga alone fails drachm doses of tincture of hyoscyamus may be added to it. The liquor caulophyllin et pulsatillæ co. in drachm doses often succeeds, or phenacetin in ten or fifteen grain doses may be tried. The neurotic cases are very disappointing to treat. A remedy which gives great relief at one time is a total failure the next. One remedy alone is fairly certain to relieve, and that is electricity. It is, however, troublesome to apply

and requires several repetitions. The use of twenty to forty milliamperes of the constant current has given me good results in some cases where both drugs and dilating had failed, the negative electrode being in the uterus and the positive on the abdomen. The introduction of the electrode is the great difficulty.

Coming now to the second class of cases, viz., those in which there is something abnormal about the uterus or its appendages, we, of course, have to pay due attention to general treatment and to relief of pain by drugs. The main question, however, is that of dilating and curetting. This operation is applicable to them all, but is more useful in some than in others, and it is important for purposes of prognosis to form some idea of what should guide us in advising it strongly or cautiously as the case may be. A good result may be expected in the first subdivision of cases, in which the uterus is normal in position and mobility, but is a little enlarged or inteflexed, or shows signs of endometritis, while the appendages are healthy. Dilating to sixteen of Matthews Duncan's dilators, followed by curetting and the use of a gauze uterine drain for five or six days, is the treatment here. The result is likely to be more lasting than if the dilatation alone is done. The following is an illustration of a successful case:—The patient was about twenty-five years of age. She complained of pain on the first two days of menstruation severe enough to confine her to bed. It was worst on the second day. It had always been present since puberty, and, for two years past, had been steadily getting more severe. Dilating, curetting, and the use of a gauze drain made her quite free from pain, and she remained so for four years, after which I lost sight of her. Her uterus at the time of operation admitted the sound 3½ inches. There was much endometrium, and some mucous polypi in the cervix. Nothing pathological could be felt about the ovaries and tubes. In the second subdivision, where the ovaries and tubes are involved, the prognosis must be very guarded. Dilatation is here rather an experimental operation than one from which we can confidently look for good results. The disease of the appendages is the essential thing. The uterus may be improved by curetting, and, to some extent, the patient's sufferings may be ameliorated, but the appendages will continue to give trouble. The improvement following treatment of the uterus is so slight as not to be noticed by the patient, who complains that you have done her no good, or even, when the appendage mischief is of a progressive nature, that you have made her worse. The following case is an example of failure. A girl, æt. 20, had had dysmenorrhœa for several years, which was steadily getting worse. The pain came on a few days before the period, and was most severe on the first day. There was a well-marked ante flexion of the uterus. Under chloroform the sound passed the normal distance, and the right ovary was found to be adherent. An ill-defined thickening in the right broad ligament also existed. Dilating and curetting and the use of the gauze drain was followed by no improvement. Subsequently pessaries and drugs of many kinds were tried without benefit. Some years ago the American writers strongly advocated curetting for tubal disease. They argued that, the uterus being the *focus* from which the tubes were infected, the removal of the primary disease would benefit the secondary extensions or allow the tubes to drain. The truth is that in most cases the symptoms depend upon lesions both of the uterus and its appendages. The more the uterus is at fault and the less the appendages intervene the greater the benefit from curetting, and *vice versa*. Curetting the uterus probably does not benefit the tubes at all. Unfortunately, the ap-

pendage mischief mostly so overshadows the uterine trouble that the removal of the latter is hardly appreciated by the patient.

The third and last subdivision includes those who have displaced and more or less adherent uteri and appendages. They are as hard to relieve as the preceding group. Here again you might try dilating and curetting and replacement as a last resource, but the hope of substantial permanent improvement is slight.

It may occur to some of you that we might open the abdomen and break down adhesions and remove diseased appendages in some cases, or do ventro-fixation of the uterus in others. This specious German idea appeals to the imagination, but unfortunately it will not do in real life. Removal of uterine appendages for pain, unless there is gross disease necessitating their removal on other grounds, is a mistake. The woman who has painful ovaries will almost certainly have painful stumps. The same applies to fixations. The most thorough breaking down of adhesions and the most accurate attachment of the uterus, whether by ventro-fixation or by vagino-fixation, or by shortening the round ligaments, will not enable you to promise improvement. If any of these operations are done for pain, menstrual or otherwise, they should only be done when all else has failed, and the fact that cure is uncertain should be very clearly stated.

In spite of the advances of modern gynecology, bad cases of dysmenorrhœa remain very difficult to remedy, and we must simply admit the fact. I regret to have to give you a report which is, to some extent discouraging, but I must speak the truth as it has been revealed to me.

THE DIAGNOSIS AND TREATMENT OF MALIGNANT STRICTURE OF THE ŒSOPHAGUS. (*a*)

By CHARTERS J. SYMONDS, F.R.C.S.,
Surgeon to Guy's Hospital.

AMONG the earlier symptoms of malignant stricture of the œsophagus there may be nausea, repulsion for food, &c., which are often taken for ordinary dyspepsia. In the central portion of the œsophagus pain alone may be present. The passage of a bougie is the only way to clear up the case. I am disposed to think that the employment of this instrument has excited in the past unnecessary apprehension, but provided a large bougie be not used, and provided also that no force be employed, there is practically no danger. In peculiarly tolerant individuals the possibility of entering the trachea must be remembered, and before introducing food it is well to examine the condition of the parts by the aid of the laryngoscope. I consider that extra-œsophageal disease rarely gives rise to any serious dysphagia. I think that "spasmodic" obstruction, apart from the "hysterical" form, has always, when marked, an organic cause, and that it would be better to speak of such cases as "intermittent" dysphagia. I may point out that both diagnosis and treatment should be considered with respect to the occurrence of the disease in three special districts, viz., the upper part of the œsophagus, the central part, and the cardiac end. In the first, it may be stated that all organic obstruction is due to malignant disease, which in this situation has a special tendency to cicatrise rapidly. In the central part, sarcoma or a myoma, both rare diseases, may cause fatal obstruction. In this situation a pouch may give rise to some diffi-

(a) Abstract of Paper read at the Laryngological Society on June 6th, 1902.

culty in diagnosis, but can generally be excluded. In the lower end alone, simple stenosis may occur, and in this situation it may also be difficult to distinguish the disease of the œsophagus from a cancer of the stomach which has caused great reduction in the size of the cavity (leather-bottle stomach). In estimating the extent of the disease I would call special attention to the great value of the steel bulb, and draw your attention also to the value of the Coudé bougie in difficult cases of obstruction of the lower end.

In the matter of treatment I consider that a patient may be left alone so long as he can swallow fluids and semi-solids well, and so long as a small bougie (No. 12 catheter gauge) can be passed. If, however, the dysphagia increased, even though a bougie can be passed, then a tube should be inserted or gastrostomy performed. If, again, a bougie cannot be passed, or only with difficulty, then the same course should be followed, as complete closure may occur at any time; and, lastly, if the patient cannot swallow and a bougie cannot be passed, then immediate mechanical treatment is required. My view in reference to the passage of bougies with a view to dilating the stricture is injurious, in that it irritates the parts and leads to an increase of obstruction. The treatment, like the diagnosis, must be considered according to the position of the obstruction. In cricoid obstruction I have found that a short tube is badly tolerated; the long rubber tube, however, gives excellent results. If even this be badly tolerated gastrostomy must be performed, and this as early as possible. In disease of the central portion I have found the short tube very serviceable in a fair number of cases. When it acted well it was superior to any other method. If pulmonary symptoms arise it is necessary to replace it by the long feeding tube. In disease of the cardiac orifice tubage is so uncertain that I consider gastrostomy to be the best method of treatment when dysphagia becomes serious.

The Milroy Lectures.

TYPHOID FEVER. (a)

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By W. H. CORFIELD, M.D. Oxon., F.R.C.P., &c.,
Professor of Hygiene and Public Health, University College.

THE lecturer defended the name typhoid fever as that used by Louis and Jenner, and as being the least objectionable name to give to the disease, pointing out that the name of enteric fever is a bad one, not only because it gives the name to a general disease from a particular lesion, but because it suggests the false idea that the disease is due to that lesion. He proceeded to give a short history of the subject from the beginning of the last century, first introducing a hitherto unknown author, Dr. Christopher Mayr, of Vienna, an unopened copy of whose Latin work on fevers, published in Vienna in 1806, he had found in the library of the Royal Medical and Chirurgical Society of London. He stated that there is no other copy of this book known in London, whether in the British Museum or anywhere else, and that the leaves had not been separated when he found it. This author gives an admirable classification of fevers into genera and species, the different forms of typhus forming his second genus, and including typhus fever and the oriental plague, which were confused together until long after that time, the occidental plague or American yellow fever, all of which he regarded as

contagious, and three varieties which he regarded as non-contagious, and which were evidently, from his excellent description, varieties of typhoid fever.

This author also gave a most interesting disquisition on the contagion and on the causes of these diseases. It is remarkable also to note that he includes phthisis pulmonalis among the fevers, though he does not say whether he regards it as contagious or not.

The lecturer then gave an account of the work and views of MM. Louis, Chomel, Gaultier de Claubry, Montault, Rochoux, and other French physicians, some of whom considered typhus and typhoid as the same disease, and others as different diseases. After alluding to the work of a number of other investigators, especially Dr. Lombard, of Geneva, and Dr. Shuttuck, of Boston, he gave an account of an important paper, read by Dr. H. C. Barlow before the Parisian Medical Society on February 6th, 1840, on the distinction between typhus and typhoid fevers. In this paper Dr. Barlow described the differences between the two fevers, and decided positively that they were quite distinct from one another. Two months after this Dr. Alexander P. Stewart also read a paper on the same subject before the Parisian Medical Society, but, contrary to the opinion generally held, he did not advance the knowledge of the subject in any way by his paper, and in fact did not lead us as far as Dr. Barlow had already done. The work of Prof. Forget, of Paris, on follicular enteritis (even a worse name for the disease than enteric fever) was next alluded to, it being quite clear that Prof. Forget thoroughly understood what typhoid fever was, and that it was a different disease from typhus.

Such was the position when Dr. William Jenner (afterwards Sir William Jenner, Bart., G.C.B., President of the Royal College of Physicians), undertook the investigation of the question. As he had been Resident Medical Officer of the London Fever Hospital, he had had an excellent opportunity, of which he made the best use, of observing cases, both of typhus and typhoid fevers, and in 1849 he published his admirable paper on the identity or non-identity of those diseases. He proved to a demonstration that they were different diseases, and in a subsequent paper also proved that without a doubt their causes were different.

It was reserved, however, for Dr. Charles Murchison, in his able paper read before the Royal Medical and Chirurgical Society of London in 1858, to demonstrate that typhoid fever is caused in some way or other by water, air, and soil contaminated with foul organic matters. In his great treatise on the continued fevers of Great Britain, he maintained that the poisons of those diseases were generated *de novo*; that of typhoid fever from decomposing excrement.

In 1873 Dr. William Budd produced his masterly work on the disease, proving that "typhoid fever is in its essence a contagious or self-propagating fever."

The lecturer finally quoted from his own paper "On the Alleged Spontaneous Production of the Poison of Enteric Fever," read before the Epidemiological Society in March, 1874, when he combated the views of Dr. Murchison, and maintained that the disease was infectious and had a special poison, which was not generated *de novo*, but was always derived from a previous case of typhoid fever. The correctness of this view has now been established by the discovery of the organism peculiar to the disease.

In his second and third (final) lectures, Professor Corfield gave detailed descriptions of a number of outbreaks of typhoid fever which had been traced to specific contamination of drinking water, and exhibited a table which he had prepared demon-

strating the fact that during the ten years 1891 to 1900 (with the exception of 1897) typhoid fever has been more prevalent in St. George's, Hanover Square, in November and December than in August, September and October, the months when it is normally prevalent, the average number of cases per month for November and December having been 7.2, and for August, September and October only 4.2. This excess of typhoid fever in November and December was coincident, he said, with the increase in organic matter in the water supplied by the Thames companies when the river was in flood. He pointed out that Mr. Shirley Murphy, the Medical Officer of Health of the London County Council, had drawn attention to the fact that in 1894 there was an excess of typhoid fever in November and December in the London districts supplied by all the water companies, except the East London and the Kent companies, and that this followed exceptional floods in the rivers Thames and Lea. Dr. Corfield stated that he was satisfied from these facts that the distribution of inefficiently filtered river water during November and December was the cause of the increase in the number of typhoid fever cases which occurred among persons especially liable to the disease.

Among the cases of polluted well water described by him, perhaps the most interesting and remarkable was one which he had recently investigated at a country house where there had been a case of typhoid fever, and where, by a peculiar arrangement of the suction pipes of a pump, water was, in certain circumstances, syphoned automatically from a pond polluted with the house sewage into the well supplying drinking water. He then described a number of outbreaks in which the poison of typhoid fever had been distributed by means of milk, oysters, cockles and mussels, ice-creams, ginger-beer, and even oranges and grapes, these fruits having been thrown, because they were decaying, into an ash-pit where typhoid excreta had been previously put, and having been picked up and eaten by a number of children. Among the reports quoted were some from Belgium, France and Germany, kindly sent him by Dr. Kuborn, of Seraing-Liège, Dr. Brouardel, of Paris, and Dr. Pistor, of Berlin, respectively, and also some from different parts of the United States, and others by Dr. J. Ashburton Thompson, the President of the Board of Health of New South Wales.

In concluding his account of the communication of the disease by foods, the lecturer stated that in 1871 he was called on to inspect the house at which His Majesty (then Prince of Wales) was supposed to have contracted typhoid fever, and reported the results of his investigations in a letter which appeared in the *Times* of January 22nd, 1872, in which he showed that, although there were certain sanitary defects in the house in question, there were no such defects as had been previously described. For instance, it had been said that the water-closet in their Royal Highnesses' suite of apartments was directly connected with a cesspool beneath them, and that its soil-pipe was not ventilated. Neither of these statements was true; there was no cesspool under the water-closet at all, nor, indeed, anywhere on the premises, and the soil-pipe was fully ventilated. There was, in fact, nothing the matter with that water-closet, and it is certain that His Royal Highness did not get his attack of fever from any foul air in it. There was, however, a defect in a water-closet in the middle of the house, and he was unable to say positively that the outbreak of the disease was not due to defective sanitary arrangements. On looking through his notes, made some thirty years ago, he had come to the conclusion that, although it was proved that the outbreak was not caused by water or milk, it was in all probability

caused by some other food (such as oysters or salad) which was partaken of by His Royal Highness and other gentlemen of the party and some of the men-servants (among whom all the cases occurred), perhaps at a shooting luncheon, but not by the Princess of Wales, or by any of the other ladies or female servants. Had the outbreak been caused by the insanitary condition of the premises, it would certainly have attacked some of those who were most in the house, whereas it attacked those who were most out of doors and some of those who did not sleep in the house at all.

He then described cases in which the disease had been distributed by means of sewer air and by the washing and mangling of clothes. The questions of ground water and of direct infection were also considered. An account was given of the behaviour of the typhoid bacillus in various circumstances, and the lecture concluded with a reference to the prevalence of typhoid fever in South Africa and its probable dissemination by means of dust and flies, as well as by water, and with some tables of statistics showing the great diminution of the death-rate from the disease in England and Wales, and also in Paris, during recent years. The increase of the disease in Paris during the years 1899-1900 was not peculiar to that city, as it was shared by London and England generally, and it was only heard of because the Paris Exhibition was held in 1900.

THE SALT BATHS OF BEX.

By EUGENE DE LA HARPE, M.D.,

Privat-docent of Bacteriology at the University of Lausanne;
Physician to the Baths.

BEX-LES-BAINS is situated in the Rhone Valley, some twelve miles from the Lake of Geneva, on the railway Lausanne-Brigue, access thereto being by train via Paris-Lausanne; from the railway station by electric tram. It lies on the right bank of the Rhone, and is surrounded by high mountains which envelop the Rhone Valley east and west; the Dent du Midi (10,450 feet) to the S., and opposite, the Dent de Morcles (9,400 feet) being the most important peaks, which render the protection against wind as complete as possible.

There are a great number of walks and tours, either in the valley or up in the mountains. Electric railways are carried up to several mountain villages. These enable pedestrians who are not very strong to obtain exercise down hill without too much fatigue. The Grand Hotel des Salines and its baths lie half a mile away from the village of Bex at an altitude of nearly 1,400 ft. They stand in the middle of a large park, close to the mountains and the forests, and in the immediate vicinity of the Avangon stream. The climate is mild and sedative, the air pure, and the absence of wind is very remarkable, the only strong wind occasionally felt being the *foehn*, the well-known warm south wind of the Alpine valleys. In the warm summer days mornings and evenings are cool, refreshing atmospheric currents coming down at night from the mountains.

Spring and autumn are the seasons preferred by English people, especially the spring. Owing to the mildness of the climate, the bathing season begins early (April 1) and closes late (end of October). The best months are May, June and September; October is generally very fine and especially appreciated by pedestrians, cyclists, &c.

Mineral Waters.—The bath establishment gets its salt water from mines in the mountains north-east of Bex. The cold brine is very nearly saturated, containing 308 per mille of chlorides (chloride of sodium, 275; potassium, 2; calcium, 22; magnesium, 9). This brine ranks also among the most concentrated of Europe (Rheinfelden, 312 per mille chlorides; Droitwich, 310; Biarritz-Biscous, 298; Salies de Béarn, 248; Ischl, 236, &c.). The *eau mère* (*Mutterlauge*) has nearly the same strength, 314 per mille chlorides, and besides, 0.2 iodide and 0.9 bromide of magnesium. Used for baths and also, diluted, for drinking. Baths are prepared at diffe-

rent strength, generally beginning with 2 or 3 per cent. salt and increasing the concentration in the course of the cure. In most cases a certain quantity of *mutterlaug* is added to the bath; it is considered to have stronger resolutive properties than the common brine. It is also taken internally as a resolutive and laxative, and applied externally to the skin by means of "Priessnitz" packings.

A cold sulphur water containing between 20 and 40 per mille volumes of sulphuretted hydrogen and 2.3 per mille of chloride of sodium is used for drinking, inhalation, spray, gargle, &c.

The bath establishment possesses, besides the salt baths, a complete hydrotherapeutic installation, with water at 48° F.; also Nauheim baths, prepared by means of liquid carbonic acid, and apparatus for inhalation. Other means of treatment are baths with extract of pine and local applications of fango of Battaglia. Fango is a volcanic mud collected out of some warm lakes of Italy. It is applied very hot to the diseased joints or limbs, the patient being then wrapped up in blankets.

Grape cure is made from the beginning of September, first with grapes sent from the Valais, and later with those from Bex itself. Both kinds are of the white *chasselas* variety, very rich in sugar.

Indications.—Bex can be advised in all cases where the salt medication is useful; lymphatism and scrofula, rickets, the combination of baths and climate being especially good; chronic diseases of the female generative organs, exudates and remains of acute processes in the pelvis; also such remnants in the abdomen after perityphlitis, appendicitis, peritonitis, or in the chest after pleurisy; chronic rheumatism, rheumatoid arthritis, &c. Anæmic and neurasthenic patients come to Bex for the hydrotherapeutic treatment.

The sedative properties of the air have an evidently favourable action on nervous excited patients.

Fango is a kind of treatment which requires patience from the invalid as well as from the doctor; but I found it very useful in certain cases of rheumatism and gout, and the more so in neuralgia, neuritis, in fact in many cases where nervous pain is great. In sciatica it does sometimes wonders. It is good also in chronic exudates of the pelvis in females.

It is needless to dwell here upon the value of the artificial Nauheim baths, so well known in England. It suffices to say that the climate of Bex is favourable for cardiac patients, and that it is very easy to make here a "terraincur," the country offering roads and paths of various declivities. In cases of chronic inflammation of the respiratory organs, especially of the larynx, and in asthma, the climate proves also extremely beneficial. Tuberculous patients are not received in the establishment.

Transactions of Societies.

LARYNGOLOGICAL SOCIETY OF LONDON.

A MEETING of this Society was held at 20, Hanover Square, on Friday, June 6th, the President, Mr. E. CAESSWELL BABER, being in the chair.

Mr. CHARTERS J. SYMONDS opened a discussion on "The Diagnosis and Treatment of Malignant Stricture of the Œsophagus," which will be found on page 680.

Dr. HERBERT TILLEY related two cases illustrating the apparent simpleness of the early symptoms for malignant stricture of the Œsophagus. The first case was originally diagnosed as ulcer of the stomach. There was no difficulty in swallowing. On examining the case the left vocal cord was found to be paralysed, and about three inches down the trachea a small nodular mass projected into its lumen. The patient died from hæmorrhage, and on post-mortem examination a malignant ulcer of the lower end of the Œsophagus was found. The mass in the trachea was a secondarily infected mediastinal gland. The second case occurred in a man, æt. 51. He complained of loss of voice, flatulence, anorexia, and inability to swallow solid food. On examination complete bilateral recurrent paralysis was found. Attempts were made to pass an Œsophageal bougie, but even the smallest one was arrested opposite the lower end of the manubrium sterni. On further examination

a mass of stony hardness was observed in the region of the left lateral lobe of the thyroid. The patient died, but no post-mortem examination was made. Dr. Tilley thought these cases suggested that invaluable information as to the cause of the patient's symptoms might be obtained by the use of the laryngoscope.

Sir FELIX SEMON pointed out the value of the presence of laryngeal paralysis and enlargement of the cervical glands as aids to diagnosis. He thought alterations in the voice were often present before the ordinary symptoms of malignant disease of the gullet. In cases where the disease affected the posterior aspect of the cricoid cartilage, the substance of the posterior crico-arytenoid muscles became affected and caused a myopathic paralysis of one or both of these muscles. This might produce respiratory defects of greater urgency than the difficulty of swallowing. Paralysis might also occur by involvement of the laryngeal nerves when the disease was situated lower in the Œsophagus. He considered enlargement of the glands, and especially those felt on deep pressure behind the clavicle to be of diagnostic value. He agreed with the advice which Mr. Symonds had given, namely, in cases where great difficulty was experienced in passing a bougie, to prescribe a night's rest and a dose of opium previous to further attempts. He considered that the dangers of chloroform in these cases should not be underrated, and related a case in which unfortunately death had occurred. He thought that functional or spasmodic stricture, apart from organic, certainly occurred.

Dr. E. CLIFFORD BEALE called the Society's attention to the possibility of diagnosing growths of the Œsophagus by means of the X-rays, and showed some photographic plates which had been kindly lent to him for the purpose by Dr. Hugh Walsham. He thought that this method of examination gave more information as to the amount of thickening and growth present. Referring to the case related by Mr. Symonds, in which a patient after gastrostomy had been able to swallow with comfort, he suggested that this good result was produced by rest and freedom from irritation. Other similar cases had been reported and acting on them, he was then treating a case by getting the patient to swallow hot water after every meal in order to wash the Œsophagus, and afterwards to swallow a sticky mixture of opium. The result so far had been most satisfactory. He agreed that intra-thoracic disease seldom caused dysphagia.

Mr. H. B. ROBINSON emphasised the importance, which had been pointed out by Sir Felix Semon, of the enlargement of the cervical glands and instanced a case where a mass of glands above the right clavicle had been the first sign which finally led to a diagnosis of stricture of the Œsophagus. He also instanced a case of cystic adenoma of the thyroid which had caused dysphagia by pressure, which was relieved by operation.

Dr. J. DONELAN related a case of malignant stricture of the Œsophagus situated sixteen inches from the teeth, in which a long bougie had been of great use. Its introduction had been considerably aided by the use of cocaine, and he suggested that adrenalin might also be useful.

Dr. DUNDAS GRANT related some difficulties which he had experienced in this class of case.

The PRESIDENT doubted the value of Œsophagoscopy from a diagnostic point of view and referred to the value of letting the patient sip a solution of cocaine or eucaine before the introduction of bougies. He had not obtained much assistance from the Röntgen rays. As regards anæsthetics in these cases, he could not help thinking there was some peculiar danger. He asked Mr. Symonds whether he had had any experience of Œsophagectomy in these cases, and whether he would give a few more particulars about the risks of gastrostomy.

Mr. C. J. SYMONDS in replying thanked Dr. Tilley and Sir Felix Semon for raising the question of laryngeal paralysis and its value as an early diagnostic sign. He had seen cases where laryngeal paralysis had helped him in the diagnosis, but as a rule he had been able to settle it on other grounds. He could not recall any case where enlargement of the cervical lymphatics had

led him to the diagnosis of malignant stricture of the œsophagus, and was glad to learn of Mr. Robinson's case. He had had one case of spasm of the sphincter at the lower end of the œsophagus which might be called spasmodic stricture. Referring to Dr. Grant's difficulties, he suggested the use of the steel bulb, without which he would certainly have missed many cases. He was interested in Dr. Donelan's case, but held strongly that long tubes were inappropriate for disease of the cardiac orifice owing to the many disappointments he had had. Answering the President as to the danger of gastrostomy, he was not prepared at the present time to give a definite answer; if performed at an early stage it should involve very little risk.

INFANTILE CHOLERA.

THE treatment of acute gastro-enteritis (infantile cholera) of young children has been the subject of a recent article by Dr. Marfau, and, as the season is approaching in which this affection is more frequently met with in infants, especially those who are artificially fed, it may be useful to give the experience of the author. Since gastro-enteritis of infants has its origin in the decomposition of the contents of the stomach and the intestines, it is certain that by suppressing temporarily alimentation the source of the evil is arrested. Yet up to late years it had been considered very dangerous to withdraw, even for a short time, from infants their natural food. But, as M. Marfau remarks, it is not abstinence from milk that the child ill supports, but abstinence from water. Consequently the medical attendant should be careful to replace the milk which he suppresses by an equal quantity of boiled water.

In grave cases of infantile cholera, says the author, all kinds of nourishment should be suppressed at the outset and only pure water allowed. If milk is continued the vomiting diarrhoea will persist, and the general condition become aggravated, as any alimentary substance introduced into the digestive tube becomes putrefied, increasing thereby the virulence of the microbes and give rise to toxins.

Pure water can alone be ingested without inconvenience. The water should naturally be sterilised by boiling a few minutes; it can be given cold and very freely for twenty-four hours. If at the end of that time the vomiting and diarrhoea have ceased, and the temperature of the child has fallen to the normal, a gradual return to the usual nourishment might be commenced, but frequently during the day the boiled water will take the place of milk. If after the first twenty-four hours the condition had not improved, the hydric diet might be prolonged for a similar period.

Although the digestive disturbances may have disappeared, the condition of the patient grows worse, acute cachexia sets in and a fatal termination results. In such cases, says M. Marfau, the cause lies in the fact that the treatment had not been commenced early enough, and the organism was impregnated with microbes or toxins which could not be eliminated. To obviate this difficulty, he associates with the hydric diet injections of salt water, a powerful eliminator of microbes, and has rarely in consequence had to deprecate a fatal re-

sult of the affection. At the same time, he prescribes bathing twice or three times a day in water at 95° F. during five or ten minutes. These baths calm the nervous system, regulate the temperature and favour diuresis. Of therapeutic agents he prescribes calomel in fractional doses, and salicylate of bismuth.

An easy way to prepare lécesthine:—

Raw eggs (yolk), 3x;

Water, 3ij;

Beat up, add

Glycerine, 3xi;

Chloride of sodium, 3ij

Cherry-laurel water, 3iij;

Syrup of lemons, 3iv;

Rum, 3ij.

Two tablespoonfuls three times a day.

BERLIN, June 21st, 1902.

At the Free Society of Surgeons Hr. Schäfer related a

CASE OF PUNCTURED WOUND OF THE SPLEEN.

The patient was a young man who had received a stab in the left side from a dagger, and who immediately collapsed and was taken to hospital. The wound was in the fourth intercostal space and in the mid-axillary line. At first there was neither exudation into the pleura nor pneumothorax, nor bloody expectoration. Appearance, however, altered during the course of the next few hours. The patient became restless and cyanotic, the pulse frequent and small, a large hæmaturia formed in the region of the wound and effusion into the left pleural cavity. Operation was performed by Madelung nine hours after receipt of the injury. The wound was enlarged downwards, and omentum soon came into view. The seventh and eighth ribs were resected, and the ninth to eleventh cut through, and the opening was enlarged to the crest of the ilium. A clear view was now obtained into the left pleural cavity, which was filled with fluid, non-clotted blood. The left lung was compressed, but some breathing took place in it, and it was not injured. In the diaphragm was an opening through which a portion of the omentum had escaped. In the spleen was a wound which was sutured over, over which also the omentum was fastened by suture. The stomach was uninjured, and there was no blood in the abdominal cavity. This had all escaped into the pleural cavity through the opening in the diaphragm. The patient recovered slowly but completely.

A speaker related the case of a woman who had fallen on her left side on to the corner of a chair and had a rib fractured. The day after she was admitted into the Charité with great anæmia and a very bad pulse. The abdomen was quite soft, but contained a large quantity of exudation. Laparotomy was performed, and one to two litres of blood were found in the abdominal cavity. On passing the hand round he felt a torn organ below the diaphragm, but could not tell at first whether it was spleen or kidney, and he was only certain when he had the pedicle of the former in his fingers. It was impossible to suture the spleen, and the only thing left was to extirpate it. This was easily performed, the whole operation lasting only

twenty-five minutes. This was a week ago, and the patient had begun to recover slowly.

Hr. J. Israel gave a communication on

SURGERY OF THE URETERS.

A man who had suffered pain in the left lower abdominal region for twelve years, noticed a swelling in 1900 for which he was operated on in Port Elizabeth, where he then was. After that the whole of the urine escaped from the opening made. This wound closed on an incision being made in the lumbar region, but now a fistulous opening remained in this part, which the speaker satisfied himself ran inwards and downwards. No kidney could be felt. All the urine ran away through the fistula. Methylene blue was now injected through the fistulous opening, and the opening then closed, and by the cytoscope a small quantity of the solution was seen to escape through the opening of the right ureter, nothing at all coming through the left. By blocking up the fistula about 200 grammes of urine entered the bladder, then tension was set up and the plug forced out. A diagnosis was made of fistula into the pelvis of a solitary kidney of which the right ureter was scarcely permeable, the left not at all. He now sought to get at the pelvis by a lumbo-inguinal incision, but did not succeed. He then brought the edges of the fistula together after freshening them, but fever, pain and retention of urine following compelled him to remove them. Some time later he made an extra-peritoneal incision into the bladder, and quite to the left made a fistulous opening through the bladder and abdominal wall, and this he united to the fistula in the pelvis of the kidney by a metal tube. This was armed at both ends with indiarubber tubing, and so placed that they closed both fistulae tightly. In this way the patient was kept dry, and the urine was not decomposed.

In a second case a fistula remained after parturition, between a ureter and the uterus. For the relief of this there were two routes, the abdominal and intravaginal. For improvement of the first he had thought out his extra-peritoneal method. This operation consisted of four steps: (1) Lumbo-inguinal incision; (2) stripping back of peritoneum and searching for the ureter; (3) freeing of it and severing of it between two ligatures; (4) implantation of the ureter into the bladder. In order to find the ureter the vasa spermatica was sought for, as well as the point of division of the iliac artery, both of them easy to find. When found the ureter should be followed as far down as possible before implanting it. The implantation was easy so long as the bladder was movable and the ureter could be stretched. Neither was the case here, and on attempting to free the stump of the ureter and rendering it movable the superiority of the extra-peritoneal method was evident. A further advantage was that if later on there was leakage at the point of suture neither the peritoneum nor the retro-peritoneal connection tissues became infected in consequence of it.

At the Free Society of Surgeons, Hr. Köhler related

A CASE OF STRUMECTOMY

with a peculiar feature. When the capsule was freed an extraordinary number of large vessels came into view, which bled considerably. The speaker therefore sought for the superior thyroid artery and vein, and tied them. He then enucleated the tumour, the bleeding still being very profuse. He then placed a ligature round the

isthmus, and removed the left half. He then proceeded to check the hæmorrhage, and had to ligature over sixty vessels, as packing was quite useless. For safety he used silk ligatures, which had to come out later on by suppuration. Recovery was comparatively rapid, and a recurring paralysis that came on at first, disappeared.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, June 21st, 1902.

OSTEOMYELITIS TRAUMATICUS.

At the "Gesellschaft der Aerzte," Von Eiselberg exhibited two cases of considerable interest. The first was a man with an epithelioma of the nasal septum, which had recurred several times. Treatment had totally destroyed the bony support, and to repair this defect, he had performed an osteoplastic operation with remarkable success; and although he renounced König's method of operation, and advised not to interfere, no bad effects have as yet supervened.

He then showed a labourer, æt. 28, who in his youth fell on the ice and injured his right thigh, which appears to have been treated at the time with splints and extension bands. Three years later great shortening of the limb set in, apparently in the femur. This was associated with some pain, which gradually increased with fever till an abscess formed, leaving a fistula which discharged for several years before it closed.

Eighteen years after the injury he developed idiopathic vesical catarrh, with tenesmus and cloudy urine; at the same time the fistula commenced to redischARGE small quantities of fluid, and finally all the urine passed through the fistula, and nothing came through the urethra. On examining the bladder with the sound a large calculus entirely filling the contracted bladder was found. The morbid changes may be divided into two epochs: first, a traumatic fracture of the femur with subsequent osteomyelitis and formation of a calculus blocking the orificium internum and forcing the urine through the fistula which appears to have penetrated the bladder, consequent upon the osteomyelitic destruction. The Röntgen rays showed the position of the stone clearly, the head of the femur being quite destroyed. The true treatment in this case could not be doubted, viz., to remove the calculus by suprapubic section.

CONGENITAL MYCROGNATHIA.

Lorenz exhibited an eight weeks old child with a malformation of the right lower jaw. The right ear and lower part of the right side of the face were quite absent.

PITYRIASIS RUBRA.

Löwenbach showed a patient with pityriasis rubra according to Hebra's diagnosis. The disease began about eighteen months ago on the internal side of the thigh. It then extended above and below as well as laterally, till it now involves almost the whole surface of the body with a diffuse erythema throwing off a fine scurf; this is associated with multiple swelling of the lymphatic glands. The differential diagnosis from acute eczema was based on the absence of a primary efflorescence; from psoriasis by the absence of a large amount of scales; from lichen ruber by the healthy condition of the mucous membrane of the mouth; from atrophica cutis idiopathica by the absence of atrophy or

any inflammation and that cigarette paper appearance of the skin; from mycosis fungoides by the presence of the glandular swellings; and from lymphodermia perniciosa by the normal state of the blood.

MECHANICAL ABSORPTION.

To determine whether a substance insoluble in water passes through the wall of the intestine is an important point in therapeutics. For example, can bacteria pass through the uninjured wall of the intestine? Secondly, What value can be placed on a drug when we have to calculate the intestinal absorption? To determine how far this can be estimated, Hofbauer used alkanna red with fat as an insoluble body in water, which becomes intensely red in acid and neutral solutions. He fed dogs on sausages to which 10 per cent. of alkanna tincture was added, after which the bowel was examined. The mucous membrane of the bowel was found to have red corpuscles incorporated in the tissues, which proves that the fat was absorbed without going through the changes of saponification, or the insoluble colouring matter would have changed its colour into a deep blue by the alkaline reaction before it was thrown off by the bowel or absorbed.

RELATION BETWEEN STRUCTURE AND FUNCTION IN THE SPLEEN.

Helly in his paper on the subject of the structure and function of the spleen first described the organ as contained within a capsule and formed of a fibrous trabecula containing the vessels and pulp or white and red corpuscles. The controversial point of the anatomy and physiology lies in the vascular structure of the organ, viz., whether it is a closed or an open or intermediary organ. Microscopic investigation and injections confirm the former. Nowhere is there a cavernous space or conducting vessel to be seen leading from the organ beyond the lymphatic pencils in the trabeculae. Some vessels enter the Malpighian bodies and are lost in the network, while others turn into the veins at right angles. In the centre is found a thin membrane of endothelial cells with large nuclei through which red and white corpuscles appear to pass. Foreign bodies may also pass as the large corpuscle of hens and frogs may be seen going through. One peculiarity is that all foreign matter causes these glands to swell at the same time, producing a large number of white corpuscles.

Exner thought that a vascular system that could pass such large corpuscles could not be called a closed organ. Helly said the question was not so much the nucleus or cell of the organ, but whether the blood vessels had a regular entrance and exit which he was inclined to answer in the negative. Kraus asked if the author had experimented with other organs as to the passage of blood corpuscles. Helly said they took three minutes, and owing to the brief period were negative in result. Kraus said he asked this question as Brede and himself had experimented on other glands with bacteria such as liver, kidneys, pancreas, &c., and after fifteen minutes no bacteria could be found in any of them, even after days when examined.

Helly said that dogs' blood could be found fifteen minutes after injection in the spleen of a guinea-pig.

SURGEON-GENERAL EVATT has been appointed principal medical officer of the Second Army Corps at Salisbury.

Continental Notes.

[FROM AN OCCASIONAL CORRESPONDENT.]

THE BATHS AND HOTEL DES SALINES, BEX, VALLEY OF THE RHONE, SWITZERLAND.

On the recommendation of a distinguished London physician of Swiss origin I found myself at the beginning of May at the above hotel in charge of an invalid member of my family—a married lady of middle age slowly recovering from prolonged anæmia. The fact that among the 150 visitors already assembled in the hotel and villas attached to it fifty at least hailed from the British Isles served to show that the hotel was tolerably well known, at least to some classes of English folk. It is, however, certain that neither Bex as a health resort nor the baths are sufficiently well known to the medical profession, and I am therefore sending these notes for the benefit of the readers of THE MEDICAL PRESS AND CIRCULAR. For the accompanying account of the baths (inserted on page 682) I am indebted to Dr. de la Harpe, the accomplished and popular resident physician. He, however, modestly says nothing in praise of the bath establishment, which I consider deserving the highest commendation; in every respect it will compare not unfavourably with any similar establishment on the Continent.

It would be impossible to find a Swiss hotel more beautifully situated than this, standing high in the luxuriant valley of the Rhone, and surrounded on every side by lofty, snow-clad mountains. The hotel throughout is thoroughly warmed by radiating steam pipes. This was appreciated during the first weeks of May, when the weather at Bex, as throughout the whole of Europe, more resembled mid-winter than early summer. The hotels of Switzerland, always among the best in Europe, have improved vastly in every essential in recent years, and, in regard to sanitation and sanitary appliances, everything is of the most modern construction and conducive to health and comfort. The food and cooking have been equally improved, and one finds a difficulty sometimes to understand (and this applies strongly to the Grand Hotel des Salines) how so much luxury and comfort can be provided at the relatively moderate charges which the hotel tariff enumerates.

My patient began to improve at once under the influence of the fine air, the beauty of the scenery, and the change of climate.

My experience and the information I have acquired on the spot would lead me to describe this place as an admirable resort for convalescents or merely delicate individuals (not to speak of the cases of distinct disease dealt with by Dr. de la Harpe in his communication) during the spring and early summer months. No doubt Bex must be somewhat hot during the height of summer, but with the waning temperature of September and October one can understand that the climate would again assume a delicious quality. To this fact also I have had ample testimony; whilst I have been able to observe the beneficial effect of both the climate and the baths in a number of cases (besides that under my own care) to which my attention has been directed during my stay of several weeks.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

FIBROMA OF SCAPULA.—ATTEMPTED REMOVAL OF SCAPULA.—Mr. MAYO COLLIER operated on a girl, *æt.* 20, who was the subject of a large growth springing from the anterior aspect of the scapula. The history of the case, he said, was an interesting one, in so far as the affection had been mistaken and treated for lateral curvature of the spine. She had worn a support for a considerable time without reducing the prominence of the scapula or the asymmetry of the spine. The girl applied for further treatment, and came under the observation of his colleague Mr. Jackson Clarke. Mr. Jackson Clarke was able to make a diagnosis of new growth of the scapula springing probably from the concave anterior surface and extending inwards towards the dorsal spines. After an exploratory incision, the exact nature of the growth was ascertained, and an attempt at the complete or partial removal of the scapula was decided upon. The girl having been put under gas and ether, a large curved incision was made extending from the scapula to some distance below its posterior border. This was followed by an incision along the spine of the scapula, provision being duly made for arresting the alarming hæmorrhage that, as Mr. Collier pointed out, so often accompanies operations of this kind. A separate assistant was told off to take charge of the subclavian artery, and compress when requisite. This precaution was, however, found quite unnecessary, the growth being extremely hard and bloodless, and the vascular supply of surrounding tissues not unduly increased. On dividing the attachments of the trapezius from the spine of the scapula and the rhomboids from its posterior border, the extent of the tumour could be more clearly ascertained. It was hard and cartilaginous in consistence, and was found to invade the whole interior aspect of the scapula. It protruded beyond the posterior border, nearly as far as the spines of the dorsal vertebræ as well as into the axillary space. The tissues surrounding it were rapidly divided, and the scapula lifted up from the ribs as far as possible. It was now found that the growth was extensively attached to the ribs and had invaded the intercostal spaces and probably the chest cavity. An attempt was made to separate the mass from the chest wall, but the extent and nature of the attachments rendered this impossible. A part of the growth, about one-third (all that could be got at), was removed and the wound closed, as offering the patient the best chance of prolonging her life. Mr. Mayo Collier said this case was interesting from several points of view. Certainly in its early stage it was most likely to be mistaken for spinal trouble. A correct diagnosis was impossible. The operation, so far as it went, was comparatively speaking a bloodless one, and but for adhesions of the ribs and the invasion of the chest cavity by the growth, could have been completed without serious loss of blood. The growth itself, he remarked, was unusual. It was not the ordinary sarcomatous type. It was (at least the portion examined) pure fibrous tissue, of cartilaginous consistence almost as bloodless as a turnip. The prognosis was, he thought, so far hopeful.

The girl, some time after, was fatter and looked better.

The scapula was in better position, and she was free from most of the discomforts experienced before the operation.

ST. MARK'S HOSPITAL.

EXCISION OF HIGH-LYING CARCINOMA OF THE RECTUM.—Mr. SWINFORD EDWARDS operated on a woman, *æt.* 39, who had been troubled with bleeding from the rectum off and on since November last. She had but little pain, but the practitioner, on making an examination, discovered a lump in the rectum, quite four inches from the anus. On examination under an anæsthetic Mr. Edwards was able to verify the diagnosis of carcinoma which entirely surrounded the bowel and occupied about two and a half inches of the length of the rectum, its lower margin being, as before stated, about four inches from the anus. The affected area was so stenosed that it was with difficulty that the finger could be got through, but once this was effected it was found possible to pull the bowel down, showing that the growth had not involved the surrounding structures. Under these circumstances Mr. Edwards advised excision in preference to colotomy. The operation was forthwith carried out in the following manner. The bowel having been thoroughly washed out with a 1 in 6,000 sublimate solution, a dorsal incision was made externally from about the middle of the sacrum to the anus; the lower part of the sacrum and coccyx having been dissected free of the soft parts, Badenheuer's section of the sacrum was made, that is to say, the sacrum was chiselled through at about the level of the third posterior sacral foramina. The lower part of the sacrum and coccyx having been removed *en masse*, the posterior connections of the rectum were freed and a large number of bleeding vessels tied. On dissecting round the rectum on its right side the peritoneal cavity was opened with design, and the finger passed in hooking round the rectum. By this means the bowel and included growth were pulled up into the operation area; the rectum was now cut through well above the tumour, and this last pulled downwards and freed anteriorly; it was now found that the peritoneal coat lying over the disease was puckered and tightly adherent to the growth, in fact it looked as though perforation were about to take place. The diseased portion of the rectum was next removed by cutting through the bowel well below the growth after arresting all hæmorrhage by the ligation of numerous vessels in the rectal walls. The large rent in the peritoneal cavity was carefully sutured, after having seen that the cavity itself was free of all blood clot. The upper rectum was now sutured to the lower in its entire circumference by numerous interrupted fine silk sutures and a long black vulcanite rectal tube passed through the anus well into the upper rectum. The operation was completed by suturing the skin towards the upper part of the wound, and the insertion of gauze tampons around the sutured bowel. The operation took two hours, owing, as Mr. Edwards remarked, to the fact that until the peritoneum had been freely opened it was difficult to bring up the bowel into the field of operation, for, as was seen during the operation, the bowel was bound down by the peritoneal adhesion. He also mentioned that one infected gland was found which was of course removed. He further remarked that it was very advantageous to

restore the continuity of the rectal canal in fitting cases, for the patient was then able to use the normal anus, and was not troubled with subsequent incontinence. In operating by the method he had employed, he pointed out that it was not always necessary to remove a part of the sacrum, as sufficient room is often obtained by removing the coccyx; but in this case the growth was situated so high up that a transverse section of the sacrum without first removing the coccyx was thought to be advisable.

The patient bore the prolonged operation well and was but little collapsed after it. A few days afterwards she was doing well.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 25, 1902.

HOSPITAL REFORMS.

THE Board of Superintendence of the Dublin Hospitals, whose report has been recently laid on the table of the House of Commons, has a knack of hitting upon remediable and important errors in hospital management. In its report of last year it called attention in very definite terms to the necessity "that discrimination should be exercised to ensure that the funds provided for charitable relief should not be spent upon persons who are competent to pay for such advantages." This year it draws attention to another blot on hospital management—the admission to the general wards of hospitals of patients suffering from pulmonary tuberculosis. There is no doubt that the present system errs gravely in this respect. A patient in the last stage of phthisis is admitted to a hospital on account of a sudden attack of hæmoptysis, or he is sent in by a subscriber who considers that he is performing a charitable action; or he is admitted on account of some intercurrent disease, or suffering from the effects of accident. He is placed in a bed in a, perhaps, crowded general ward, and no precautions are taken to guard against the extension of infection to others, save perhaps by the placing

of a little carbolic lotion in his spitting cup. When the patient leaves the hospital what must be his ideas of the consequences of his condition so far as others are concerned? If he is an uneducated man, he has received no impressions on the subject. If he is an educated man, he reasons to himself that if the medical authorities consider it safe for a patient, suffering perhaps from bronchitis, to live two feet from him, it will not harm his relatives, who are healthy, if they do the same. This is the unfortunate point in the present hospital arrangement. Not only are the fellow-lodgers of the consumptive made victims, but indirectly, his relatives and friends. The evil of such a procedure is admitted on all sides, indeed it would be impossible even to condone it, but still nothing is done. For this reason, the suggestion of the Board of Superintendence, that in each hospital there should be two suitable wards allotted for the reception of tuberculous patients, is most important. Such an arrangement would not, of course, afford accommodation for any appreciable proportion of the number of cases of phthisis occurring in Dublin, but it would afford accommodation for the few phthisical patients which are admitted to a hospital. Another suggestion of the Board is worthy of note—"Several hospitals possess suitable adjoining grounds for the erection of shelters with the help of which the 'open-air treatment' could be instituted with great benefit to judiciously selected cases. The number of consumptive patients who could thus be treated would of necessity be very limited, yet sufficiently large to offer a useful demonstration of the efficiency of open-air treatment even when practised in the midst of a city." We fear the surroundings of city hospitals are not—save in a few cases—such as would enable the open-air treatment to benefit consumptives. But in these few cases, there is no reason why the suggestion of the Board of Superintendence should not be carried out.

THE HYPNOTIC HABIT.

SOME correspondence has taken place in the lay press concerning the poisonous effects of sulphonal when taken regularly or in large doses. It was started by the relative of a person who, it was stated, had developed symptoms of insanity consequent upon the prolonged use of the drug. Other correspondents assert on the contrary that they have taken it for long periods of time without any appreciable effect upon the general health. Admitting that clinical observations recorded by non-medical persons do not possess that element of scientific impartiality which is indispensable to sound scientific conclusions these contradictory assertions are none the less of interest. It is obvious that no narcotic or hypnotic can be perfectly safe, they all comport an element of danger; in other words, it is merely a question of dose. Now individuals react very differently to drugs, some being vastly more sensitive than others, the difference being no doubt in large measure due to the ease with which the drug is decomposed in the

organism and in the rate of elimination. It follows that the effects must vary *ad infinitum* consequent upon circumstances of which we are, for the most part, left in ignorance. This ignorance is not one of necessity but of omission, that is to say, the public do not take the precautions observed by every medical man of carefully noting the action of a given quantity of a drug on the organism. That sulphonal, for example, should produce insanity is intrinsically improbable, though by determining a grave disturbance of function of one or other organic system it might conceivably evoke a latent taint of insanity. That taken habitually in large doses it gradually induces progressive debility, culminating, it may be, in coma and death, is quite within the scope of possibility; indeed, in presence of renal insufficiency, such a result is even probable. It is important that the public should be led to understand that the arguments advanced against sulphonal apply with approximately equal force to hypnotics in general. We repeat that there is no drug of this class which can be methodically taken to procure sleep without ultimate, and occasionally very prompt, damage to the organism. It is positively appalling to witness the thoughtlessness with which people have recourse to powerful drugs of this kind. They suffer from sleeplessness, attributed to worry or overwork, but most frequently due in reality to some vicious habit—the abuse of tobacco, alcohol, tea &c., or to dietetic irregularities, in other words, to causes absolutely within the control of all, and forthwith they conceive themselves to be called upon to absorb toxic drugs without inquiring whether the symptom would not be amenable to more physiological measures. The public should be taught that the use of hypnotics is at best but the lesser of two evils and that in the majority of instances the remedy is decidedly worse than the disease. One disquieting feature is the ease with which most of these drugs can be procured from the retail chemist without medical authority. The habit of self-medication is so ingrained in certain classes of society, indeed in most, that it seems idle to ask for more stringent regulations in respect of the sale of potent substances. Sufferers from insomnia should be impressed with the fact that it is but the symptom of disturbed function, and should be made to understand that it is absurd to suppress what is in reality a warning, regardless of the mischief that may be brewing within. There is no reason to believe that sulphonal is more dangerous than chloral or any one of the numerous group of substances which the industry of the coal-tar chemist has placed in the hands of the physician. Nor, on the other hand, does it present any distinctive advantages of its own. It is asserted that the tendency of the public to employ these substances is in large measure due to the “recklessness” with which they are prescribed by medical men, but this is a mere excuse, although it is possible that medical men are not always as mindful as they ought to be of the responsibility which they assume in prescribing them.

ANTI-VIVISECTIONIST REASONING AND A BRITISH JURY.

ONE of the many curious phases of human nature is that particular sensitiveness portrayed in the parable of the man with the beam in his own eye who wished to remove the mote from that of another person. An amusing instance of that kind of one-sided vision, which sees wrong only in an opponent, was brought to light last week in the King's Bench Division of the Law Courts. The action was laid by Mr. Stephen Coleridge, the well-known secretary of the National Anti-Vivisection Society, against a Dissenting minister at Derby to recover damages for libel. The gist of the statement on which the action was based appears to be that the methods of the plaintiff and of his Society consisted in the “suppression of the true and the suggestion of the false.” That, by the way, is the precise ground on which THE MEDICAL PRESS AND CIRCULAR has challenged the Anti-Vivisectionist Society in general and its secretary in particular. The sentence in question merely expresses the conclusion that Mr. Coleridge uses arguments that are not in our opinion logical, and that they therefore cannot be accepted as established. It seems extraordinary that a man with the training of a lawyer should confuse the expression of a purely intellectual difference with the accusation of a moral offence. That is the simple fact, however, if we may accept the statement made by the plaintiff in the witness box that he considered the letter of which he complained was a personal attack, as it inferred he was a liar. At the same time, he admitted that he himself was a hard hitter in controversy and expected good blows in return. Quite so:—Mr. Coleridge is in the habit of accusing the medical profession of heartless and wholesale acts of objectless cruelty upon the lower animals. When, however, a country clergyman questions the soundness of his reasoning, he replies to that “hard blow” by bringing an action for libel. The jury showed their sense of the grievance of this hard-hitter by stopping the case, and saying the action should never have been brought, and the judge pointed out that Mr. Coleridge must not be too thin-skinned when he himself was attacked. The dismissal of this action plainly shows what value a British judge and jury attach to Mr. Coleridge's judgment and intellectual methods. To play the part of Don Quixote and attack an honourable profession by every species of quibble and unfair argument may be an amusing pastime. It needs no logical reasoning, that is to say, it needs no absolute, irrefutable truth to convince persons of the kindly but feeble intellectual type of which antivivisectionist audiences are usually composed. It is another matter, however, as by this time Mr. Coleridge himself is aware, to force illogical views upon the sound common sense of a British judge and jury. For our own part we have been unsparing in our condemnation of Mr. Coleridge's methods. In dispute he is master of the art of special pleading, that is to say, of ignoring all facts hostile to his own

views, and of freely availing himself of every kind and species of fallacy. The fact of the matter is that the legal mind need not necessarily be logical. We do not for a moment question the sincerity of Mr. Coleridge's position, in spite of what we consider his unfairness of attack, but while we admire his humane tendencies we cannot admit that his mind is capable of trained reasoning. In controversy Mr. Coleridge has a way of avoiding main issues that is peculiarly characteristic of a special pleader. Does he eat the flesh of animals? If it be permissible to destroy the lower animals in order to maintain human life, is it not equally permissible to make experiments upon them with a view of prolonging human life by making it more secure from sickness? If the one thing be defensible as an abstract proposition, surely so is the other, unless it is maintained that mankind has no right to attempt to cure sickness. Surely, if it be right for man to avoid death by starvation by eating the lower animals it cannot be wrong for him to avoid death from sickness by subordinating the same lower animals to scientific experiment. These are fairly plain issues which may be settled on purely logical grounds apart from the necessity of showing that science is enabled to cure sickness by comparative experimentation. That point is mentioned simply to confine the issue so far as possible within a small compass. Were the medical profession to resort to the law courts for a judgment as to anti-vivisectionist attacks it is likely that the hands of Mr. Coleridge and his party would be fully occupied for some considerable time to come. We are sorry to see that so worthy a cleric as Archdeacon Wilberforce allows prejudice to blind his sense of justice. It is said that on Hospital Sunday he informed his congregation that one collection would be made for the Lord Mayor's Fund and another for the Anti-Vivisection Hospital "run" by the Hon. Stephen Coleridge. If this be so we consider the archdeacon is adopting an unworthy and an un-English method in the "support" of his anti-vivisection propaganda, and one that for logical justice may compare favourably with the proceedings of Mr. Coleridge.

Notes on Current Topics.

An Interesting Case.

SENOR FALPHY PLANA reports a case of a boy who (*Arch. de Ped*) had a severe attack of appendicitis which terminated in the formation of an abscess and was followed by copious purging of fœtid, purulent stools. The appendicitis was followed by peritonitis, and from the history of the case it appears as if the inflammation on the under surface of the diaphragm excited some pleuritic and pneumonic adhesion on the thoracic surface. Through this inflamed area the pus in the peritoneal cavity made its way and communicated with a bronchial tube through which it was evacuated. Don José Falphy writes: "The exhaus-

tion produced by percussion and auscultation produced a violent paroxysm of coughing which continued for at least half an hour, when the patient seemed in the jaws of death; he vomited up in my presence a quantity of pus. It was so fœtid that it became necessary to admit all the air possible, for the atmosphere was irrespirable." For some days he continued to cough up pus, which gradually lessened in quantity and became less fœtid; ultimately he made a good recovery. Cases of abdominal abscesses opening into the bronchi are very unusual. One of the earliest recorded is that of the elder Monro. In his case a hepatic abscess was discharged through the bronchi and for long afterwards the patient spat bile, and one of the latest is that of Dr. Gabriel, whose patient spat up 400 ounces of bile. But it is even more unusual for a peritoneal abscess to be evacuated by the bronchi, and we think Don José Falphy Plana's case well worthy of record.

London's Natality.

THE recent Census returns have afforded material for much discussion and useful research. One of the most important and interesting points raised is that which concerns the natality of the metropolis. Mr. T. A. Welton, at a meeting of the Royal Statistical Society on June 17th, drew attention to the falling birth-rate, and showed that the number of children in London between the ages of ten and fifteen was at the present time 164,000 less than would have been the case had the old proportion of children been preserved. The fertility of marriages appears to have so much diminished that the decrease in London now equals 26,000 births yearly. This is a matter of national importance and demands consideration.

Medical Supplies during the War.

Now that the land enjoys the blessings of peace it may not be uninteresting to look back on some of the work of the military and civil surgeons, more especially during the first period which ended in March 1900, with the relief of Ladysmith after a siege of four months. A glance at the list of drugs used during that time will enable us to form some idea of the work of the medical officers. Commencing with anæsthetics, we find that 132 lbs. of chloroform were issued, and 49½ drachms of cocaine. The chloroform issued was sufficient to anæsthetise 10,000 patients; of ether the amount issued was 10 lbs. 15 ozs., a relatively small amount. Of boric acid. 115 lbs. was issued and of carbolic acid 99 lbs. As might be expected, opium was much in demand; of laudanum, 113 lbs. were requisitioned; of liquid extract of opium, 40 lbs. 1 oz.; of tincture of chloroform and morphia, 65 lbs. 6 ozs.; of tincture of ipecac and opium, 4 lbs. 1 oz.; of wine of opium, 8 lbs.; of paregoric elixir, 109 lbs. 6 ozs.; of aromatic powder with opium, 48 lbs.; of powdered opium, 5 lbs.; of morphia, 1 lb. 10 ozs. Besides this, 21 lbs. of chloral were consumed. And if we would estimate fairly the work done by the medical officers we may add to these the

list of surgical necessities: Medicated wools, 3,819 lbs.; 10,417 yards of medicated gauze; and 10,585 bandages. In the four hospitals at Intombi on January 1st, 1900, there were 1,205 patients under treatment, not counting the drivers, coolies, &c., which brought the total to 2,557. That all the difficulties were overcome redounds greatly to the energy and resourcefulness of Lieut.-Col. Stoneman, A.S.C.

Languages and Medical Education.

THE question of what to teach our boys and girls is always a vexed one, and it is unlikely that any system capable of universal application will ever be devised. So far as the medical profession is concerned, no general agreement has hitherto been arrived at with regard to the languages desirable for a good standard of preliminary education. The one language that can most readily be dispensed with is probably Greek, which, in almost all cases is blotted out from the memory after a few years of general practice. There seems to be a modern tendency to cultivate languages that will not only serve as a means of training the intellect, but will also have a practical value in everyday life. Latin, French, and German appear to answer those conditions, and are certainly most popular among the languages set forth in the medical curriculum, and of these Latin and German are unquestionably the most important, though for some reason French is generally preferred to German. Perhaps the most generally neglected language is English, and it is astonishing how few matriculation students who have a smattering of Greek, German, and Latin, can read and write their mother tongue with the accuracy of assured and competent knowledge. As a means of educating the mind and at the same time of furnishing it with a subject of perennial usefulness English is by far the most valuable language that could be taught to the embryo medical student.

Army Enteric Fever.

THE lessons of the South African campaign will doubtless be cut deep into the minds of men, and will one day lead to valuable and practical reforms. Meanwhile, there is likely to be the usual weary time of probation while the wisdom of the War Office is reposing, chrysalis-like, in the splendid solitudes of Whitehall. If the weakness of any one branch of the Service has been absolutely and hopelessly exposed it is that of the Army Medical Service, which owes its chances of reform to the courageous conduct of a civilian journalist rather than to its *ex parte* defence by the Government. What has the Department done in two and a-half years of constant experience of enteric fever to lessen the incidence of that disease upon the troops? Judged by results no effective plan of dealing with the malady has been devised, for the cases were not reduced in numbers up to the last day of the campaign, and are still occurring with unabated severity. Yet we are told that enteric fever was practically excluded from certain volunteer detachments who habitually boiled

their drinking water. What is possible in the case of volunteers may surely be attainable on the part of regulars. Anyway, the fact demands explanation that in two and a-half years the Army Medical Department with unlimited resources at command has been unable materially to reduce the decimation of troops under its charge by so entirely preventable a scourge as that of enteric fever.

Fees for Medical Evidence.

IT is wise for a medical man called upon to give medical evidence in Court to insist upon being paid in advance. Otherwise, especially in the large class of speculative cases undertaken by lawyers on behalf of impecunious clients, he probably will find he has wasted his valuable time and given his skilled testimony for nothing, not even gratitude. Recently in Yorkshire a medical man insisted upon being paid before giving evidence, and maintained that position firmly in spite of the taunts of the plaintiff's attorney and the pressure of the judge. The plaintiff had brought an action to recover £50 damages against a school teacher for assaulting her son. Her case was dismissed as incredible by the Court, so that the medical man would in all likelihood have had an extremely remote chance of receiving any fee had he been foolish enough to contribute his evidence. Why should a lawyer be permitted to reckon upon gratuitous medical evidence? If the client be substantial enough to bring an action then the payment in advance of a medical witness is no hardship. If the client be unable to pay the medical witness let him say so in an honourable, straightforward manner and not attempt to secure evidence under false pretences. The present writer knows a medical man who was subpoenaed in a similar speculative school assault case. He was detained several days in a strange town. On coming to trial the case was contemptuously dismissed, and he never received a penny in spite of the repeated previous assurances of plaintiff's solicitor that all expenses would be paid.

Allegations against a Public Vaccinator.

AN extraordinary incident which has occurred at a meeting of the Maidenhead Board of Guardians deserves comment from various points of view. So long ago as April 6th last, one of the guardians stated that a certain public vaccinator had made a charge for re-vaccination of a person by whom he had been paid privately. That serious charge was not upheld, but the complainant said he would consider the matter further before giving the names of those concerned. On June 11th he stated that whilst he maintained his ground he should choose his own time for substantiating his allegation. The Committee therefore very properly reported that the charges were unsubstantiated. It is simply scandalous that any public man should be able to act in this manner, and it seems likely that there would be substantial grounds for immediate action on the part of the medical man concerned, or failing the disclosure of his name, on that of the local public public vaccina-

tors as a body. There can be no official privilege sufficient to protect a Guardian from bringing unsupported charges of fraud against a public officer. Even supposing the fee to have been paid twice over, an extremely unlikely occurrence, it is quite possible that there may be an adequate explanation forthcoming by way of inadvertence or otherwise. In any case a public officer is at present labouring under an odious accusation made in the dark. If he belongs to the Medical Defence Union or one of the kindred protection societies, as every medical man ought to do, he would probably get his case taken up at once.

Insanity in South Wales.

THERE appears to be little reasonable doubt that insanity is on the increase in all parts of the United Kingdom. Reports of deficient accommodation and of new asylums are familiar and universal. An illustrative case is that of Cardiff. Formerly, that town was able to provide for all its lunatics at the Glamorgan County Asylum. But the accommodation that proved sufficient for the past generation is unequal for the wants of the present, and for some time past Cardiff has boarded out a hundred lunatic patients in neighbouring county asylums. The general increase of insanity, however, will in all probability soon lessen the number of "foreign patients," as they are termed. Under a statutory provision Cardiff has been ordered to find accommodation for all its lunatics by April, 1904. A large new asylum is to be built at a cost of a quarter of a million, but some doubt exists as to whether it will be ready at the appointed time. To meet that state of affairs Dr. H. T. Pringle, the Medical Superintendent at the Glamorgan County Asylum, has recommended the erection of a temporary hospital to house three hundred patients. With regard to this suggestion it may be remarked that the Lunacy Commissioners exact somewhat stringent conditions as to the quality of temporary buildings of the kind. The reasons of the general increase in lunacy are worthy of the closest scientific investigation in the interests of the community at large.

The Vagaries of Newspapers.

A PAPER called the *Anglo-Celt*, which we learn is published in Cavan, copies from our columns Dr. Minchin's article on the treatment of tuberculosis by garlic, not alone without any acknowledgment of the source from which it is taken, but in a manner which is directly calculated to bring Dr. Minchin into discredit with his professional brethren. The article in the columns of the *Anglo-Celt* is headed in large letters "Certain Cure for Consumption Discovered by a County Meath Doctor.—What Dr. Minchin has Achieved." The article itself starts with the statement that "personally we do not know Dr. Minchin . . . nor have we received a scrap of paper from him eliciting (*sic*) our assistance . . . we are not aware of his religion, his politics, or any of the other potent factors which now-a-days are first inquired into before a man's worth is considered." It then continues:—"As usual with anything

Irish, the English medical papers have boycotted all reference to the discovery, our Irish dailies, with the exception of the *Independent*, which took it from the *Anglo-Celt*, with acknowledgment—treating it in the same indifferent manner. To some the alleviation of man's suffering only touches the heart when there is a jingling of what Shakespeare calls 'saint-seducing gold.' Then come the remarks of grateful patients, and the suggestion that a sanatorium should be at once built, and, lastly, Dr. Minchin's paper, reprinted from our columns without acknowledgment. The impression left by the whole article on any ordinary reader would be that Dr. Minchin had inspired it, and that it was a gross breach of medical etiquette. As "consumptive cures" have led many men into trouble, we thought it well to draw Dr. Minchin's attention to the utterances of the *Anglo-Celt*. The result, as we expected, has been an absolute denial of any connection with the reproduction of his article. We would point out to the *Anglo-Celt* that it is dishonest to copy an article from a scientific journal without acknowledging its source, and that it is disgraceful to distort it into the form of a gross attempt at advertisement on the part of the author. We sympathise with Dr. Minchin in the false position into which he has been drawn by an imitation of Yankee journalism by an irresponsible newspaper.

The Midwives Bill and Trained Midwives.

WE regret to find that a more satisfactory response has not been made to the requests of the authorities of the Rotunda and Coombe Hospitals for some guarantee of the position of their diplomées under the Midwives Bill. These chartered hospitals asked that the powers which had been conferred upon them by charter should not be swept away by a Bill brought forward under the guise of an attempt to improve the training of midwifery nurses, and that their certificate should entitle the holder to registration. The answer to this has been that the special recognition which Clause 2 confers on nurses holding the certificate of the Royal College of Physicians of Ireland and of the London Obstetrical Society has been extended to them. This sounds as if it was a matter of importance, but when it is looked at more closely, it is shown to be valueless. Clause 2 provided that nurses holding the diplomata alluded to, and who, within two years from the date of the Act coming into operation, claim to be certified under the Act, shall be so certified. It also provides that any woman who produces evidence satisfactory to the Board that she has been in *bona fide* practice for one year and that she bears a good character must also be admitted within a like period. Consequently, the Rotunda and Coombe Hospitals have been granted the valuable concession that their nurses need not produce any evidence of character, otherwise their position is identical with that of any "handy woman" through the country. We cannot believe that this was the amendment to the Bill which Mr. T. P. O'Connor, M.P., and Mr.

Gordon, M.P., believed they were obtaining. It certainly was not the amendment which the Royal College of Physicians of Ireland requested Mr. O'Connor to bring forward. There is, however, as yet no need for the hospitals to give up the hope of carrying their point. The Bill will certainly have fresh amendments made to it during the Committee stage in the House of Lords, and the hospitals are sufficiently powerful and influential bodies to have no difficulty in finding supporters there. We trust that they will put their shoulders to the wheel, and not lose their position through mere want of effort.

The Chronometry of Life.

THE normal evolution of the organism implies a certain synchronism of events, not only in respect of the growth of the various parts of the organism, but also in regard to its environment. Any disturbance of this synchronism is attended by suffering, deformity or other physical incapacity. In the ordinary course of nature, once wrote Sir James Paget, the time rates of each creature are adjusted to those of the external conditions most necessary to life. Such adapted changes in parents for the sake of their offspring are everywhere to be seen, and so are instances in which the development of animals of all kinds keep time with those of plants or other animals on which they live. It follows that the evolution of all living things depends in great measure on their mutual adjustment in time as in all other conditions of life. Some persons, for instance, develop more rapidly than the normal, while others are obviously behindhand. Delayed growth is often the direct consequence of intercurrent disease and, passing from the general to the particular, we find that the growth of particular structures may be similarly delayed or prevented. The development of the teeth for instance, is frequently checked by an attack of some acute fever and the growth of limbs or groups of muscles may be arrested for a time as the result of disease of certain nerve centres. Now there is a time-limit for growth and if the process be hindered permanent deformity may ensue since the time still available may be insufficient to allow of arrears being caught up. Premature development is sometimes as disastrous as when it is delayed since there results a want of harmony between the component parts of the organism. We see this well in the teeth when irregular dentition leads to overcrowding and decay. Premature greying of the hair and precocious baldness are examples of chronometric irregularity, and this obtains also in respect of other organs of the body, the want of harmony between the various organs thus entailing more or less marked and serious departures from physiological health. Many cases of failure of health are doubtless due to these errors in the chronometry of life, and the truth of this assumption is confirmed by the adage that a man is as old as his arteries. Many conditions ascribed to disease are in reality merely due to a falling out of the rank of particular organs or systems, thus introducing a potent source of perturbation into the vital processes.

A New Form of Malingering.

THE extent to which malingerers will go in order to produce the particular symptom by means of which they hope to delude the medical inspector is well known, as is their ingenuity in finding unexpected methods of procedure. The South African war has served as a means of instruction in many directions, but perhaps the most curious information which it has imparted is that of a new method of causing a temporary elevation of the temperature. In a recent number of the *New Zealand Medical Magazine*, Surgeon-Captain Purdy, a medical officer of the Sixth New Zealand Contingent, relates how some of the men in his Company were admitted to hospital with a temperature of 103° F. to 104° F., which within twenty-four hours subsided to normal. The cause of this temporary elevation of temperature was perplexing until it was ascertained that it had been obtained by the ingenious expedient of eating cordite. This means of raising the temperature was discovered by the men, who noticed the effects of cordite fumes when lighting a pipe with a stick extracted from a cartridge. It would be interesting to know the manner in which the internal administration of cordite produces this effect.

The Parliamentary Representation of Dublin University.

A CIRCULAR has been addressed to the medical electors of Dublin University by Mr. A. H. Ormsby-Hamilton, M.A., D.L., announcing his intention to come forward in the event of a Parliamentary vacancy. In its course, Mr. Ormsby-Hamilton says, "The Members of the Great Professions of Medicine and Surgery may at all times rely upon my hearty furtherance of measures calculated to maintain their dignity and advance their interests." The importance to all Irish medical men—not merely to graduates of Dublin University—of having a representative for Dublin University who is interested in the affairs of their profession is very great. There are quite sufficient medical electors in the University to materially influence the fate of any candidate who asks for their votes, and we would strongly impress upon them the importance of assuring themselves that their votes are given to one who, not merely before election, but during his whole parliamentary career, may be relied upon to support the interests of the medical profession.

The Coming Presentation and Banquet to Earl Roberts.

THE long-deferred presentation by the Irish University Graduates to Earl Roberts is to take place on July 8th next. It was originally intended that it should have taken place some time ago, but at the expressed wish of Earl Roberts it was postponed until the South African war was over. A large sum of money was collected, the greater part of which was, at Earl Roberts' request, given to the Fund for the Widows and Orphans. Sufficient, however, was retained to purchase a presentation cup, which will be handed to Earl Roberts after a banquet at the

Victoria Hall at the Hotel Cecil. The banquet will take place at 7.30 p.m., the Right Hon. W. E. Lecky, M.P., in the chair. The hon. secretaries will be glad to receive the name of any Irish Graduate who by inadvertence has not received a notice of the forthcoming presentation, and who may desire to subscribe. All such names should be sent as soon as possible to 2, Henrietta Street, Cavendish Square, London, W.

Fires in London Hospitals.

THE disastrous fires which have recently occurred in London have drawn attention to the inadequate provision for the escape of people from many workshops and private houses. But if difficulty exists in the escape of the strong and healthy from a burning building, the removal of the sick and incapable is a task well nigh impossible, unless under the best organisation and with the most efficient management. It is well therefore that those responsible for the care of the physically and mentally defective in our great London hospitals and asylums should consider their means of dealing with fire. We understand that only too many of the hospitals in the Metropolis are quite inadequately provided for such an emergency. Structural arrangements offer almost insurmountable difficulties in many instances. The staff receive no thorough drilling in the proper methods of "first aid." Communication with the fire station is uncertain or does not exist. Oftentimes there is no clear idea as to the quarter from which help should be sought. The nurses receive no special instruction as to proper action in the emergency of fire, and trust is put in a blind hope that British pluck will be sufficient to allow the danger to be "muddled through." Such neglect is little short of criminal. The matter has been prominently before the public, and we trust that hospital authorities will give evidences that every means are being taken not only to prevent the outbreak of fire but in case of need to allow of the prompt and safe removal of patients from danger to safety.

Arsenic and Cancer.

IN the reports which appeared in the newspapers of Mr. Jonathan Hutchinson's Bolingbroke Lecture on Cancer he was made to say that arsenic was the chief factor in the production of cancer. Mr. Hutchinson has since written to contradict a construction which credited him with a view which he does not hold. He adds, however, that he regards it as proved that the long-continued use of arsenic may cause cancer, and he holds it probable that it has contributed to the increase of cancer which has occurred during the last century. One naturally hesitates to dissent from a view formulated by so distinguished an authority, but we are fain to assert that even this modified view does not command the assent of the medical world; indeed, Mr. Hutchinson concedes that the influence of arsenic in the causation of

cancer is probably but small, the increase in the incidence of cancer which has caused so much alarm among the public being much more probably due, as Mr. Hutchinson suggests, to the greater longevity of the race, a larger proportion of persons now surviving to the age most liable to cancer than was formerly the case. Mr. Hutchinson's guarded utterances are not likely to be misunderstood by an audience of medical men, and it is to be regretted that they should be reported in a condensed and misleading form to the public, who are not in a position to see the facts in proper perspective.

Dreams.

WANDERINGS in Dreamland are not governed by geographical considerations or regulated by the scientific principles of travel. Dreamland still remains a *terra incognita*, and the stuff that dreams are made of yet continues unanalysed, and affords fantastic fabric for the revelling of romancers and the meandering of poets. And yet there is reason to believe that a certain degree of order might prevail where only confusion now exists, and superstition and worse might give way to at least a reasonableness of outlook if only dreams were investigated according to the scientific method. Sir Arthur Mitchell, in the current issue of the *Scottish Medical and Surgical Journal*, deals with this very attractive subject in a paper rich in suggestion, and urges that there is no such thing as dreamless sleep. During the whole continuance of sleep the mind is occupied with hallucinations. Sir Arthur believes that if a person resolves every time he is awakened from sleep to ask himself immediately whether he has been dreaming, he will generally, if not always, be aware that he has just passed out of a dream, the details of which he may or may not be able to recall. Dreaming, it would seem, may at first be wholly forgotten, but afterwards recalled. The watcher by the bedside of a sleeping person may sometimes witness what he considers evidences of dreaming, and yet on awaking the person may feel quite positive that no dreaming has taken place. It is practically impossible to determine the extent to which unremembered dreaming occurs, and, therefore, also impossible to say that it may not occupy the whole time of sleep.

Foolish Experimentation.

IT is announced that a Dr. Garnault, of Paris, in order to combat Koch's contention that there is but little danger of infecting man with tubercle from bovines, has inoculated himself with tuberculous material from a cow. He is said to have blistered his arm over an area of twelve square millimètres at a point ten centimètres below the elbow, and then after removing the raised cuticle, to have applied the pounded tuberculous glands of a cow, which had been seized by the authorities, for a period of two hours. The experiment was carried out on June 17th, and no doubt Dr. Garnault and his friends will watch the result with interest. But such a method of investigation cannot receive the support or approval

of medical men, and is not likely to further medical science.

Rheumatism of Single Joints.

RHEUMATISM, as we know, is often a refuge for the destitute in the matter of diagnosis, and this fact may serve to explain the frequency with which inflammation of a single joint is ascribed to rheumatism. There are very good reasons in favour of the view that there is no such thing as single rheumatic joint disease. If joint disease be due to rheumatism, more than one joint will be involved, but multiple joint affections are not on that account necessarily rheumatic, witness the polyarthritis met with in gonorrhœa, syphilis, and sepsis. Disease of a single joint is either purulent, tuberculous, gonorrhœal, or is due to some central nerve lesion. If the disease commences in one joint and subsequently spreads to others it is presumptive evidence that the affection of the other joints is due to secondary infection. The distinction is not merely of interest from the point of view of scientific accuracy, for it may have, and often has, a very important bearing on treatment and prognosis.

Vitalism and Mechanism.

LIFE in its essence is unknowable. Its mystery lies hidden in activity. It is the eternal problem. Recent thought has revolted against mechanical conceptions of life. Mechanism is materialism. Opinion is swinging back to ancient ways. Old methods of expression are being revived. Vitalism is recognised as an inscrutable force. Professor Bunge insists on the impossibility of giving a mechanistic explanation of psychical processes. These are, indeed, the immediate object of our experience the most real of the real. The mechanists ascribe certain qualities which are a pure product of their inner consciousness to external things, and proceed to use the same conceptions to explain all vital phenomena, imagining that by the help of these threadbare and scanty conceptions they may explain the manifold activities of the inner world of consciousness. Truly psychology and physiology are in transition. The transcendentalist exerts a wide influence. The night has come down on the materialists.

King's College.

WE are glad to see that King's College is wisely shaking itself loose from religious restrictions. In future appointments on the staff, save in the faculty of theology, religious tests are to be abolished. Ecclesiastical exclusiveness is now an anachronism, and fatal to progress in science and obstructive to the best interests of art. Although the awakening of the King's College authorities has come late in the day, it has probably saved this in many ways excellent institution from passing into the sleep of death.

Nocturnal Protection.

THE nights following the Coronation processions will be more or less sleepless for many. Mr. Henniker

Heaton estimates that there will be 100,000 homeless wanderers on the night before the Coronation, and makes the wise suggestion that churches might well remain open all night to afford safe refuge for respectable waifs and strays. We certainly think every effort should be made to mitigate the physical suffering which long standing, excitement, and absence of suitable food necessarily brings to children, delicate women, and old people.

Army Medical Reforms.

WE understand that in pursuance of the recommendations of the Committee which recently held an inquiry with a view to reorganisation of the Army Medical Service, under the chairmanship of Mr. Brodrick, it has been decided by his Majesty's Government that the next session of the Army Medical School shall be held in London instead of at Netley, as heretofore, an important concession which candidates will fully appreciate.

The Midwives Bill.

IN spite of the passive disapprobation of the Lord Chancellor, the Midwives Bill has passed the second reading in the House of Lords, so that it cannot be long before it receives its *exequatur*.

THE Raymond Horton Smith Medical Prize at Cambridge University has been awarded to Mr. Laming Evans, M.A., D.D., of Trinity College.

PROFESSOR RUDOLF ALBERT VON KOLLIKER, of Wurzburg, has been awarded the Gold Medal of the Linnean Society of London in recognition of his zoological researches.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

BELFAST.

THE MEDICAL INSTITUTE.—An active canvass of the medical profession in the country districts around Belfast is being undertaken by a number of medical men, with a view to laying before them the advantages of this new institute, and inducing them to join it. For a subscription of a guinea per annum country members will enjoy the privileges of a club where they can meet friends, have parcels or letters sent, and obtain light refreshments, as well as enjoy the ordinary privileges of membership of the Ulster Medical Society. To increase the benefits of the latter to country members, it has been arranged that in future there shall be one meeting a month at 4 p.m., as well as one at 8.30, and it is hoped that many country practitioners will join the Society and attend the meetings.

Lunacy Department.

ASYLUM REPORTS.—(Continued.)

Glasgow District—Garthloch.—This report is very interesting, and there is plentiful evidence that the reins are in capable hands, and that the administration is efficient. The changes in the population, which show an increase of fifty-five, are as follows:—268 admissions, 153 discharges, and 60 deaths. The recovery rate is 81 per cent., and the death-rate 11.5 per cent., the former

a low, and the latter a high rate. The Brabazon scheme of employment continues to be carried out to advantage, and an interesting exhibit of work done was sent to the late Glasgow International Exhibition. The cause of insanity in sixty-two of the admissions, or 23 per cent., was alcohol. Dr. Oswald makes some very discreet remarks on the importance of early treatment in all cases of mental derangement, and in dealing with the causes of deaths, of which phthisis accounts for 16 per cent., says:—"Beyond doubt the larger proportion of those who died from phthisis contracted the disease here." This appears to be rather a startling admission considering this asylum is practically still in its infancy. The "Nurses' Home" would appear from its description to be on a somewhat elaborate scale, with "attractive fittings and furnishings," and some may be disposed to question, have they not gone too far, and whether these attractions, so liberally provided, are appreciated? The maintenance and expense for the year totalled £17,297 17s. 2d., and the average number of patients resident was 522.

Woodilee.—Here, we have a business-like report, and as there was an addition of no fewer than ninety-four inmates registered during the year, there is a call for immediate extension of accommodation. It is intended to establish a separate hospital suitable for 240 patients, and a home for 110 nurses. The new villa for idiot children, the first in Scotland in coherence with an asylum, has been opened. It is well arranged, efficient for its purpose, and as comfortable as possible. It has accommodation for thirty-five children, and the assistant matron is responsible for its arrangements. The Brabazon scheme of industries is carried out successfully here, too, and provides amusing employment to a number of patients unfit for the usual asylum work. The total admissions was 323, discharges 152, and deaths 77. Of the admissions 145 laboured under the different forms of dementia, including congenitals and cases of senility. The recoveries were only 29.1 per cent. on the total number admitted, and the death-rate 9.4 per cent. Of the deaths twenty-one were due to general paralysis, and one man had been resident for 25½ years. Good work has been done by the pathologist, who, conjointly with Dr. Ford Robertson, published the results of his investigations in the *Journal of Mental Science*. The cost of maintenance per head was £25 10s. 5½d., and the farm and garden account shows a profitable balance.

Lanark District.—There is a melancholy interest attached to the Medical Report, it being the last report of the late Dr. Campbell Clark, whose name will ever be associated with Hartwood Asylum, where he did so much excellent and original work. The Commissioners report in high terms of praise on the condition of the asylum and its management. The rate of board continues the same, viz., 8/9, as also the arrangement for the reception of private patients at a low figure. There were 205 admissions, 127 discharges, and forty-seven deaths. The recovery rate, 49.3 per cent. of the admissions, is above the average, and the death-rate is low—6.8 per cent. on the average number resident. The industrial employment of the patients continues to receive special attention, 72 per cent. of the males and 68 per cent. of the females being, on an average, daily employed, and the advantages derived from the farm, financially and otherwise, have been more than ever fully demonstrated. Alcohol, as a cause of insanity, appears in 20 per cent. of the admissions. There has been only one escape during the year, and this may be regarded as indicative of strict supervision, or contentment of the patients.

Perth District.—The population has decreased by eleven, due to a very low admission rate—eighty—and an abnormally high recovery rate—55 per cent. of the admissions recovering. There is a dearth of accommodation here also, but we note the Board contemplate the erection of a detached hospital for eighty or ninety patients. Besides relieving the constrained accommodation it will be utilised for treating phthisis and infectious diseases.

Western Counties Idiot Asylum.—This report is rather

interesting, and the asylum seems to be conducted with great success. The worthy object of the institution is to provide an intellectual, physical and industrial training for feeble-minded children. The income continues satisfactory, and there are evidences of general prosperity. The total number under care during the year was 294, and a large amount of useful work has been executed. Applications for admission far exceed the accommodation. The Superintendent would like to see a change in the title of the institution. He suggests "training institution" be substituted for the obnoxious term "idiot asylum"—a sensible suggestion. The present title does not convey an accurate impression of its objects.

CHRONIC HYPERTROPHY OF THE FAUCIAL AND PHARYNGEAL LYMPHOID OR ADENOID TISSUES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—All interested in the subject, and this should indeed include every practitioner of medicine, will be gratified that Mr. Marsh has selected this subject for his Ingleby Lectures (THE MEDICAL PRESS AND CIRCULAR, June 11th), notwithstanding that it is fashionable to consider the subject so thoroughly thrashed out that nothing new that would be serviceable can be said on it.

Agreeing generally with all that is so lucidly set forth by the lecturer, I would ask permission to make one or two remarks:—

Climate.—Statistics from such observers in dry climates as Dr. Hamilton in Australasia, Dr. Tiedmann in South America, and Dr. Daly in the Indian territories of North America, go to prove that neither moist atmospheres nor those laden with the "irritating ingredients" of manufacturing districts are important factors in the production of adenoids.

Nasal Stenosis.—I quite agree with Mr. Marsh that adenoiditis is quite as likely to be a result as a cause of nasal hypertrophy, and in this connection it has to be noted that when the two co-exist in children under the age of puberty, the turbinal congestion and hypertrophy almost always disappear without further treatment on the removal of the adenoids.

But the most interesting feature is that of the *relative frequency* of enlarged faucial tonsils and adenoids. Mr. Marsh considers that there is practical agreement that the two are usually associated, and he rightly attributes the frequent failures of faucial tonsillotomy in earlier days to a non-recognition of co-existing adenoids. However, as I have pointed out in my systematic work (a) we now know that adenoids exist without enlargement of the faucial tonsils in a very large proportion, and in the Medical Report of the Central London Throat and Ear Hospital for 1901 the announcement is made that there were 1,363 operations for removal of enlarged tonsils with adenoids, 127 for enlarged tonsils only, and 615 for adenoids alone. Thus the practitioner is liable to be misled if he makes his diagnosis only or mainly on a visual inspection of the back of the fauces.

This opinion is corroborated by the invaluable report, quite recently published by Mr. Arthur Cheate, of 1,000 children in the Hanwell District School (b). Adenoids "were present in 434, although slight in amount in 39. They were associated with enlargement of both tonsils in 174 instances. Some aural trouble was present in 394. On the other hand, in 40 the ears were normal." These figures I quote at length for another reason; adenoids were slight in amount in less than 10 per cent. of the whole number in which they were present, and in this same proportion the ears were normal. The lesson to be

(a) "The Throat and Nose and their Diseases." Fifth edition. P. 414.

(b) *Journal of Laryngology*, June, 1902. P. 203.

derived is that the charge of over-operation in these cases has but a very insecure basis, and it would be fair to assume that this 10 per cent. represents the proportion to be found of adenoids in the so-called latent condition. I mean those in which, to again quote Mr. Marsh, "measles, scarlet fever, whooping-cough, and influenza are active exciting causes, the first symptoms often dating from one of these illnesses," and it is well recognised that this class of case often occasions serious aural mischief, and is generally of an obstinate character. Lastly, my own statistics of 1,000 cases of diphtheria (a) demonstrate that while the diphtherial exudation was limited to the tonsillar region in 666 cases, in only eight of the whole 1,000 was it not implicated. When to this is added the fact that in the case of enlarged tonsils in children under the age of 10 adenoids are invariably present, it must be conceded that surgical neglect of the condition is fraught with much more serious risk than surgical zeal.

I am, Sir, yours truly,

LENNOX BROWNE.

Mansfield Street, W., June 13th, 1902.

PURE WATER DISTILLATION FOR CAMPS AND ARMIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As many proposals have been made to purify the water used for drinking and cooking purposes for the army in the Transvaal and Orange River Colony I beg to draw attention to a description of a new water still in the *English Mechanic*, p. 369, of June 13th, 1902.

It would seem to be just the thing wanted for supplying troops on patrol or in camp in these up-country districts, and it could even be carried in a waggon along with the military transport in full action of distillation preparatory for use in halting. The up-country water is mostly furnished by rivers or vleys, and in both it is liable to become stagnant and contaminated with the decaying remains of wild animals and their ordure during peace time, and much more so during war time, when horses and transport and slaughtered cattle defile the streams all over the country as well. The rivers in the season become dried up into a succession of pools along their course, and get filled with dead animals, remains of beasts, birds, reptiles, and fish, and the nuisance increases till the next rains come and cause a flood, and which will sweep them all down stream, and refill the rivers and pools with fresh water.

The Gem Pure Water Still (address, 121, Newgate Street, London, for inspection), seems to be a construction of a handy character, as it is all in one piece, containing boiling water, distilled water, and condenser, and is heated by Bunsen or any oil burner underneath it.

It may be of any size, from 15 ins. high and 9 ins. diameter, to double or more dimensions, and so may be useful for officers as well as men, in tents or marquees, or huts in any camp, permanent or movable.

W. G. BLACK, F.R.C.S.G., S.M.

Edinburgh, June 19th.

THE RECONSTITUTION OF THE BRITISH MEDICAL ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The narrow majority, viz., three, by which this report was carried must have been a shock to the supporters and opponents alike of these extraordinary proposals. Some men told me they did not intend to go to the meeting, as there was no chance whatever of the report being adopted; others that they should not go because opposition was useless. Both these sections must be much chagrined to find that the presence of but two more members would have turned the scale against the disintegration of this great Association.

It is to be hoped that this apathy will be shaken up before the meeting on July 9th, and that sufficient members will be present to throw out the "Bill" at its third reading. The task, of course, is more difficult now because only a bare majority is required, but those

who were present to hear the feeble attempt of the several members of the Committee to justify their action, will certainly exert themselves to bring up a good and substantial opposition. The speakers for the report admitted that the scheme was bad, but anything was better than the present government of the Association, so "we implore you to adopt our report," "we had two parties in the work, very much opposed to each other, but we compromised!"

Now what is the result? All members forced to pay 4s. to his branch. The Association gets the same as before, 21s., but is mulct in the cost of the delegates and salaried officials for some departments which are to be created, say £1,000 a year. So much for the loss to the Association. Now for the reformers (?). They send up 300 delegates instructed to vote as they have been told. If these gentlemen pass any resolution by a two-thirds majority it is binding on the Council if the Council does not think it wrong, but the Council may take four months to think it over, and then refer it to the branches for further consideration!

Several members of the Committee say, "If you will not have this scheme what are you to do?" The reply is simple—let the branches send to the Central Council men who will work, and not elect a man in order to do him honour. Pay the representatives properly, and let them meet more frequently, and at each annual meeting let every Councillor give an account of himself to his constituents. All alterations necessary to ensure efficient working can easily be made by alteration of the by-laws without the costly process of reconstruction of the Articles of Association.

I am, Sir, yours truly,

JAS. BRASSY BRIERLEY.

Old Trafford, Manchester, June 21, 1902.

Obituary.

JOHN WYCHENFORD WASHBOURN, C.M.G.

It is with special regret that we have to record the death of Dr. John Wychenford Washbourn, C.M.G., M.D.Lond., F.R.C.P., F.R.C.S., &c., of Cavendish Place, W., Physician to Guy's Hospital and to the London Fever Hospital, one of the most promising physicians of the day, and for whom a brilliant career was confidently expected, which took place at Tunbridge Wells on Friday, in his thirty-ninth year. Dr. Washbourn, whose face and voice were well familiar in London medical circles, was the second son of the late Mr. William Washbourn, of the Blackfriars, Gloucester. He was born on June 22nd, 1863, and was educated at King's College, Gloucester, at Guy's Hospital, London, and at the Universities of Vienna and Königsberg. His career as a student was one of exceptional brilliancy. He took the Fellowship of the Royal College of Surgeons, England, in 1888, becoming a member of the Royal College of Physicians, London, in 1889, of which he was elected a Fellow in 1894. He had been appointed a demonstrator of anatomy at Guy's Hospital in 1888, and in 1890 was appointed assistant physician, physician in charge of the electrical department, and joint lecturer on physiology and demonstrator of bacteriology. Dr. Washbourn was also, in 1889, at the age of twenty-six, appointed assistant physician to the London Fever Hospital, and, three years later, physician to that institution. It is seldom that a professional man has established such a sound reputation at such an early age, and become so widely known as Dr. Washbourn was when he was little more than thirty years of age; and no stronger testimony to his sterling worth and professional abilities could have been offered than his selection by the Maidstone local authorities to inquire into and advise upon the serious epidemic of typhoid which occurred therein 1897. His scientific work in experimental pathology and bacteriology and the wide range of his inquiries had made him so widely known that when he was selected as consulting physician to the Imperial Yeomanry Hospital at Deelfontein in 1900 it was felt that no better selection could have been made, and the best results were anticipated from his visit to the seat of war. He

(a) "Diphtheria and its Associates." Second Edition. P. 35.

served in South Africa—first at Deelfontein and afterwards at Pretoria—from February, 1900, till June, 1901, was mentioned in dispatches, and was decorated with the Companionship of the Order of St. Michael and St. George.

Medical News.

Prosecution by the Pharmaceutical Society.

MR. SWIFT, K.C., the divisional magistrate, has given his decision in the case of the Pharmaceutical Society of Ireland against Mrs. Josephine Preston and Mrs. Margaret M'Dermott for keeping an open shop for the compounding of prescriptions and the sale of poisons, and that, without being qualified to do so, they compounded a prescription for one F. W. Leslie, contrary to the Pharmacy Act (Ireland), 1875. The case was tried on the 18th inst., and the decision of the magistrate given on the 20th, the summons being dismissed.

The facts are briefly told:—William Bowers, a certificated pharmaceutical chemist, owned the establishment, 164, Great Brunswick Street, Dublin, and there carried on the business of a pharmaceutical chemist. He died suddenly in 1892, and his mother took out administration of the estate, and as administrator was clearly entitled to continue the business. The estate was a large one, and had to be divided among many relatives of the deceased; before this was accomplished the administrator became ill and died. The sisters of William Bowers then took on the duty of administrators, and against them for carrying on the business the summons of the Pharmaceutical Society was issued.

The plea of the Society was that the death of the administrator terminated the legal right of unqualified persons to conduct the business, and that consequently the sisters of the deceased had infringed the law; they further pleaded that there should be a limit to the time in which the business could be carried on by trustees. It may have been necessary to the Society to get a legal decision on the question, as the death of the first administrator and the succession of others has not, we believe, ever been the subject of a legal decision. But the Act is plain reading, there is no limit of time put on the administrator of the business of a pharmaceutical chemist, though, as the magistrate pointed out, there is to the administrator of a publican's business. For the latter business there is a ready sale, but it is not so easy to dispose of the former. To confine the right of keeping open shop to the first administrator would in many instances cause grave injustice; an administrator might meet with an accidental death within twenty-four hours of his appointment, and the owners, as a rule near relatives of the deceased, be deprived of a valuable asset; this in the case of orphans might mean throwing them on the rates as paupers. All said and done, the object of the Act of 1875 is the protection of the public, the general good, not individual gain, and executors carrying on the business of a pharmaceutical chemist by pharmaceutical chemists give that protection that the Act was passed to secure. The ownership of such a business need not be exclusively in the hands of certificated pharmaceutical chemists—any limited liability company can carry on the business, as many of them do.

The Society must abide by the Act until it is changed, even though they think it needs alteration. We, however, believe that Parliament will not approve of making the meshes of the net finer. As the Act stands, it has been productive of good, and has ensured to the public a considerable measure of protection against accidental poisoning, and provided a number of trustworthy persons to compound prescriptions. But the clauses of the Act to which the Society take most exception are those which the framers of the Bill trusted to prevent the Act pressing harshly on many deserving persons without safeguarding the public by requiring that a trained and certified pharmaceutical chemist should conduct the business.

Death of a Hermit Doctor.

An inquest was recently held by Dr. G. Danford Thomas on the body of Francis Daniel Muller, *et. 73*,

who was found dead in his room one day last week. Dr. Robert Lee, a friend of the deceased, gave some interesting details concerning the eventful career of the deceased, who for some years had led the life of a recluse in rooms near Oakley Square, N.W. He was born in Germany, but fled the country in 1844 and studied medicine in Paris, subsequently going to America, where he joined the Confederate Army as surgeon. Later on he came to London, where, for a time, he mixed in good medical society, but for the last few years he shut himself up in his rooms, receiving neither visitors nor letters, until death at last surprised him.

A Lunatic in a Surgery.

DR. SMITH, a practitioner of Darwen, had a disagreeable experience a few days since. He was standing in his surgery when a man entered and at once seized him by the throat, and it was only after a violent struggle that the assailant was overpowered. He turns out to be *non compos*, but this explains, without excusing, the attack.

A Medical Motorist Fined.

MR. WILLIAM EMMOTT WILSON, M.R.C.S., L.R.C.P., of Westgate, Burnley, was fined £7 10s. and costs for driving a motor car without a light, with the result that he ran into a cab and caused much damage to the vehicle, the occupants fortunately escaping.

A Locum Tenens Arrested.

A PERSON giving the name of James Crean, *alias* William Waddell Moore, has been arrested at Bridlington on a charge of having stolen various articles of jewellery from Dr. Batchelor, of that town, for whom he had been acting as locum tenens. He claims to be fully qualified, but as there is some uncertainty as to the real name of the accused the point cannot be cleared up for the present. The prisoner was remanded.

Deaths under Chloroform.

AN inquest was held at the London Hospital last week on a man, *et. 45*, who died under chloroform, within three minutes of the commencement of anaesthetisation. No details are to hand concerning the method of administering the drug, and the usual verdict was returned.

A young man died last week from the effects of ninety minims of chloroform, "administered in the usual way," at the Southern Hospital, Liverpool, and no explanation was forthcoming of the cause of death, the organs, including the heart, being quite healthy. A verdict of "death by misadventure" was returned.

Report of the Board of Superintendence of Dublin Hospitals for 1901.

THE forty-fourth annual report of the Board of Superintendence of the Dublin Hospitals was laid on the table of the House of Commons on Wednesday last. The report begins by stating that in none of the hospitals did anything occur approaching culpable negligence or serious offence of any description. The work done during the year, we are told, was equalled, and in some instances exceeded in amount compared to former years. The quality of the work appeared to the visitors to be of a high order, and would bear favourable comparison with that of hospitals elsewhere. An opinion is expressed, however, that in some cases the pathological and bacteriological laboratories are still lacking in modern requirements. This, it is said, must impede physicians in arriving at a sure foundation for the diagnosis of certain diseases, and in procuring for their patients the full advantages of modern methods of treatment. With regard to the admission into general wards of cases of pulmonary phthisis, and as to the danger of contagion extending to other patients, the board expressed an opinion that it would be advisable to have in each hospital two suitable wards—one for each sex—allotted when practicable for the reception of such patients. It is then declared that although all the available accommodation in the city would be insufficient to cope with the prevalence of this disease, more might be accomplished than at present. The report then deals with the subject of the open-air treatment, and suggests that the public should be informed by authorities of the ways in which tuberculous diseases may

be disseminated and the means by which they may be obviated. The Board further adds that it would be advisable that strict sanitary legislation should be enforced in regard to public conveyances and buildings where large assemblies of people are gathered together. Analysing the statistics put at their disposal, the members of the board state that on April 1st, 1901, there remained 911 patients in the hospitals which are under their management. The number admitted during the year was 11,248, making the whole number under treatment 12,169, of whom 10,792 left the wards either cured or relieved, or were discharged for other causes, and 471 died. Eight hundred and ninety-six remained under treatment in these hospitals on March 31st, 1902. Exclusive of incurables, the mortality was 3.80 per cent. on those treated to a termination. The total daily average number of beds occupied in these hospitals throughout the year was 942.75. The time spent in hospital by each patient under treatment (omitting the patients in the Royal Hospital for Incurables) averaged 23.97 days.

West London Medico-Chirurgical Society.

THE annual conversazione was held at the Town Hall, Hammersmith, on Friday, June 20th, and attended by a large number of medical men. The Cavendish Lecture was delivered by Sir Frederick Treves on "Some Phases of Inflammation of the Vermiform Appendix." The chief clinical features of appendicitis were lucidly dealt with, and concise enlightening considerations regarding indications for operation were forcibly presented. A very instructive medical and surgical exhibition was arranged in the large hall, and with music, smoking, refreshments, and much conversation a delightful evening was spent.

Charing Cross Hospital.

THE Duke of Connaught, on Friday, June 20th, laid the foundation stone of the new buildings of Charing Cross Hospital, with full masonic ceremony, and expressed the wish that one of the new wards should be named the "Louise Ward," in compliment to his sister, the Duchess of Argyll, president of the hospital.

Child Study.

THE London School Board is to be congratulated on its admirable exhibition in the Medical Examination Hall on the Victoria Embankment, of the excellent samples of the work of its half-million of children in training for the battle of life. In spite of the widespread dissatisfaction and strong condemnation of much in our educational system, this exhibition certainly shows that even in the face of great difficulties much good work is being accomplished.

A Medical Semi-Millionaire.

THE late Dr. Thomas Kidley, of Sheffield, left property of the estimated value of over £500,000, and his will was contested on the ground that the testator was not at the time "of sound disposing mind." The Judge, however, decided in favour of the will. We may take it for granted that the deceased gentleman did not derive this large fortune from the practice of medicine, and this may account for the fact that he did not leave any of it to further the interests of the medical profession.

Royal Army Medical Corps.

THE list of examiners of candidates for commissions in the Royal Army Medical Corps under the new regulations is now complete. It is as follows:—

In Medicine.—Dr. Kingston Fowler (London), Dr. E. Markham Skerritt (Bristol), Dr. G. S. Middleton (Glasgow), Dr. James Craig (Dublin).

In Surgery.—Sir W. Thomson, C.B. (Dublin), Professor John Chiene, C.B. (Edinburgh), Mr. Herbert Page, M.C. Cantab., F.R.C.S. (London), Mr. Jonathan Hutchinson, jun., F.R.C.S. (London).

A Burglar Shot.

DR. JOHN OLDBERSHAW, of Wallasey, one evening in last December, detected a burglar in the act of escaping through a window of his house, and promptly lodged a revolver bullet in the body of the unauthorised intruder with such effect that it was only last week that he could be brought to judgment. The prisoner complained bitterly of having been shot, in spite of the fact that he

had offered no threats, but he was advised to reserve that argument for the jury, who will shortly have an opportunity of expressing an opinion on his conduct.

Belgrave Hospital for Children.

LORD WINDSOR on June 17th presided at the annual meeting of the above institution in its new buildings at Kennington. Over £30,000 have been subscribed towards the new hospital, but £20,000 are still required to complete the building. The hospital is intended to contain eighty beds, but at present it is being built block by block as funds will allow.

Death from Ruptured Heart.

DR. W. LLOYD, of Llandilo, died very suddenly a few days since, while on a visit to Swansea, and at the inquest it was stated that his heart was ruptured in two places, consequent upon advanced fatty degeneration. Dr. Lloyd held many public appointments, and was generally esteemed in the district for his professional and social qualities.

Cholera at Shanghai.

ACCORDING to a telegram from Shanghai, cholera is spreading there. There are now fifty deaths a day in the Chinese town. Up to the present there have been, in all, forty cases in the foreign settlements. Among those who have died of the disease is the Spanish Consul.

The Value of a Thumb.

THE defendant in an action brought in the Leeds County Court by Mr. J. J. Moran objected to the amount of the bill (£12) as unduly high for attendance involving amputation of the thumb for injury by a gun accident. The judge held that, in the absence of any evidence to the contrary, the charge was reasonable, and gave judgment for the amount claimed.

Garden Cities.

IN connection with the garden cities movement a public conference is to be held at Liverpool and Port Sunlight on July 25th and 26th, when Messrs. Lever will entertain about a thousand delegates from all parts of the country. Mr. George Cadbury has offered to subscribe £1,000 to the Garden City Pioneer Company on condition that the whole capital of £20,000 is raised. Much interest is being taken in this effort to return to the soil, and it is well that medical men and sanitarians generally should make themselves acquainted with the details of the scheme.

Pass Lists.

University of Dublin (Trinity College).

The following passed the Final Examination in Medicine, during Trinity Term, 1902, arranged in order of merit:—John S. Joly, John A. Valentine, Robert P. Beatty, Horace Townshend, M.D., Ernest B. Booth, Walter E. H. Smith, Charles M. Benson, James E. Johnston, Richard F. Steel, Wallace Benson, Harry F. Johns, John S. Wilson, George R. Harman, William A. G. Cluffe, George H. Keene.

M.B. Degree.—William H. Peile (M.R.C.S. Eng.), William Taylor (F.R.C.S.I.), Herbert L. Thurnell (M.R.C.S. Eng.).

Royal Navy Medical Service.

THE session of special instruction at the Royal Naval Hospital, Haslar, terminated on the 20th inst., when the following surgeons received appointments to H.M. ships:—Two prizes, viz., the gold medal and microscope, were awarded to Surgeon Oswald Mills, R.N., late of St. Thomas's Hospital, and one, viz., the silver medal and ten pounds' worth of books, to Surgeon Leslie M. Morris, R.N., late of St. Bartholomew's Hospital.

Surgeons in order of Seniority:—

Name.	Marks.	Name.	Marks.
Oswald Mills	5,532	William N. L. Cherry	3,863
Leslie M. Morris	5,185	John G. Peebles, M.B.	3,790
Alexander K. Smith-Shand, M.B.	4,321	Thomas W. Myles, B.A., M.B.	3,786
Norman H. Mummary	4,278	Elijah R. A. Thomas	3,444
John Fullarton, M.B.	4,245		

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

BEDFORDIAN.—The symptom you describe is common to many persons whose environment leads to a constant wetting of the finger tips. In the case of public-house servants this eczematous inflammation of the skin round the base of the nail has been named "potboy's disease." At the same time it should be observed that there are possibly other irritants concerned, and it has been occasionally reported from the use of some of the strong cleansing soaps now so extensively advertised. In all cases, again, where the symptom is well developed, there is probably some obscure factor concerned in the constitution of the patient. If you fail to cure the patient within a reasonable time it will be advisable to consult a dermatologist.

MR. F. E. P.—The subject is not of sufficient interest to our readers to enable us to devote so much space as your communication demands.

CUTTING TEETH FILLED WITH GOLD!

OUR contemporary, the *Journal of the British Dental Association*, reports that among the rubbish going the round of the American Press is a report of a child who has cut some front teeth which have the appearance of being filled with gold. This phenomenon is supposed to have resulted from the fact that the mother when pregnant paid a visit to the dentist, and had two front teeth filled with gold. It will not surprise our readers to learn that "the matter is causing much discussion among Chicago doctors."

DR. DUKE.—We hope to have space for your communication in our next.

MEMO.—For phthisical patients chloroform is probably the safer anesthetic as compared with ether, on account of the irritating effects of the latter on the mucous membrane of the respiratory tract. It must be given cautiously, preferably by the aid of a regulating inhaler, bearing in mind that the resistance of the subject is below the normal, and that the oxygenisation of the blood is less perfectly accomplished than in a healthy individual.

DR. KOLISCH.—Your request will be borne in mind when the blocks come to hand. We are holding over the translation until sufficient time has elapsed for you to make the necessary arrangements.

M. B.—It is unusual to demand a certificate of health under the circumstances mentioned, but there need be no hesitation in giving one without entering into objectionable details.

D. B. J.—The man you mention is a registered dentist. He is described in the *Register* as having been "in practice before July 22nd, 1878."

INSOMNIA.—The unconsciousness produced by an anesthetic differs fundamentally from ordinary sleep, and unless the amount inhaled be sufficient to leave behind it a state of stupor, sleep does not follow. For this reason, chloroform is an utterly untrustworthy hypnotic, and it is objectionable from many other points of view. For prompt action, not unduly prolonged, trional or paraldehyde may be recommended. Insomnia, however, is not a disease, to be treated brutally by sleep-producing drugs, rather is it a symptom, to be relieved by ascertaining and removing the cause.

Appointments.
